24,942. How do you explain the fact that plague did not commence sooner after 1881 than 1896?—The work of constructing the main drain was taken in hand in 1881. The population also began to increase, and the sullage also began to accumulate in the drain.

24,943. What is it that proceeds from this accumulation which causes plague?—The sullage and night-soil accumulating in the drain. In 1896 there was no rain for the last two months of the monsoon, and the night-soil and other sullage accumulating in the drain gave rise to the plague.

24,944. Do you mean that the accumulation polluted the air?—I am not a professional man, and I am not able to answer that question. I request you to read my précis of evidence.

24,945. I have read it. You have made some proposal as to the best measures to adopt; what do you think is the best measure?—Instead of the night-soil getting into the drain, it should be taken a long distance out to sea and thrown there, as is done in Hong Kong.

24,946. Do you believe in the efficacy of bonfires?—The bad effluvia coming from the gutters may perhaps be removed by the burning of bonfires.

24,947. It is the effluvia of the sewage which, in your opinion, is the cause of plague; is that so?—The exhalations coming from the gutters are the cause of plague, and the rats coming out of the gutters are another cause of plague.

24,948. The bonfires are intended to destroy the plague in the air?—Yes.

24,949. Are these effluvia being continually given off, or only at certain times?—The effluvium continues coming out always.

Mr P. B. Dantra.

13 Mar. 1899.

24,950. Do you propose that bonfires should always be burning?—The burning of bonfires at one place or at several places at one time will not be sufficient.

24,951. Then it requires continuous bonfires?—Wherever it is found that the atmosphere of a certain district is contaminated, the bonfires should be continued there for some time every evening.

24,952. Suppose the effluvia are bad in the daytime, should there be no bonfires to destroy the plague then?—In the morning and afternoon there are the rays of the sun; in the evening there are no rays of the sun, and bonfires should be burnt in the evening, as I do in my own street.

(Witness withdrew.)

(Adjourned till to-morrow.)

At The Secretariat, Bombay.

SIXTY-FIFTH DAY.

Tuesday, 14th March 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT. | Dr. M. A. RUFFER.
Mr. A. CUMINE.

Mr. C. J. HALLIFAX (*Secretary*).

Col. D. Robertson, I.S.C.

14 Mar. 1899.

Colonel D. ROBERTSON, I.S.C., recalled and further examined.

24,953. (*Mr. Hewett.*) Since you were before us last, you have had a considerable outbreak of plague in the Mysore city?—Yes, an outbreak commenced very shortly after, and is still continuing.

24,954. What is the population of the city of Mysore?—Seventy thousand.

24,955. Has the epidemic been severe there?—Yes, it has been severe; the total mortality, I think, had reached 57 or 58 per diem.

24,956. What system has the Darbar of the Mysore State adopted as regards the people sick of plague in Mysore town?—The system adopted in the Mysore city has been throughout the voluntary system, as opposed to the forcible system which we tried and worked so unsuccessfully in the Bangalore Civil and Military Station. The system, briefly, is the adoption of all the safeguards, or the measures that were considered necessary under the forcible system, with the exception that everything is left to the people themselves, that is to say, the acceptance of these measures is left to the people.

24,957. Do the people report cases of sickness?—The reporting is surprisingly accurate in Mysore as regards the death-rate; I am not sure about sickness; but every case of death is reported, and before interment or burning takes place a certificate is obtained from the Ward Officer.

24,958. And have you means of ascertaining that the reports of deaths are practically accurate?—I have personally satisfied myself that the reports of death are accurate, for the reason that they are prepared independently by two branches of the city administration, and they do not always agree. There is a variation of one or two, which is, in itself, a sign of honest attempt to prepare a correct total. I think there is no question about it that the reporting of deaths is accurate.

24,959. When a case of plague is reported in the Mysore city, how is the patient treated?—The house would be at once marked as infected, and the people would be urged to take the sufferer to the hospital and to vacate the house as soon as possible, in order that it might be disinfected.

24,960. Do you know whether, in the majority of cases, the people prefer to take the patient to hospital, or to treat him in his own house?—In the majority of cases they treat him in their own houses. I may mention that the State has provided men with English qualifications who go about the city and afford medical relief gratis wherever it is acceptable, but in the majority of cases the people prefer to treat the patient in their own houses

24,961. When the relatives of the patient elect that he should be treated in his own house, what is done with the other inhabitants of the house?—They are allowed to remain there.

24,962. And permitted to have free access to the patient?—Yes.

24,963. Is any attempt made to isolate the patient in one particular portion of the house?—I believe not. At one time they professed to isolate the patient, and, indeed, to turn out the people in the infected house, but after a time it was found that the attempt was hopelessly impracticable, and it was dropped, and practically now the people are left to themselves.

24,964. Between the interval of the reporting of a case of plague and the death or recovery of a patient in his own house, is any attempt made to disinfect the house?—Yes, unless the patient is practically *in extremis*, they would move him out, and disinfect the house, and put the man and his surroundings back again.

24,965. Is there any subsequent system of daily disinfection of the house?—No.

24,966. Does the patient as a rule in Mysore sleep on the floor or on a bed?—The invariable custom in Mysore, I think, is for the people to sleep on the floor.

24,967. When you gave us evidence as regards Bangalore, you told us that the attitude of the people had been anything but helpful. Do you consider that the attitude of the people in Mysore has been helpful?—I think the attitude of the people in Mysore has decidedly been helpful. This effect may partly have been contributed to by the manner in which the Seringapatam town riots were dealt with by the Darbar. The forcible measures adopted by the Darbar undoubtedly tended towards a more pacific attitude on the part of the people. I may mention that the Darbar was very apprehensive of the advent of plague in Mysore, so much so that they requested that volunteers might always be kept ready to turn out at any moment should occasion be required. Mysore containing a considerable Muhammadan population, the Darbar feared outbursts of turbulence amongst them, but up to the present time I am glad to say that these apprehensions have been entirely falsified.

24,968. Have you had many instances in which dead bodies have been thrown out in the Mysore city, as at Bangalore and in the Civil and Military Station?—I have not heard of one.

24,969. Then may it be assumed that whatever the other effects of the measure adopted in Mysore city are, it has been more successful in detecting cases of plague in the houses in which they have occurred?—Certainly.

24,970. Have you been able to observe how the system adopted in Mysore has affected the spread of plague in particular portions of the town?—One very marked feature of the outbreak in Mysore has been the slow manner in which it marched within the town; that is to say, it stuck to one particular district or muhalla of the town, and it did not, as it did in Bangalore Civil and Military Station, jump from one part to the other. The movement has been very slow.

24,971. To what do you attribute that?—I think the cause may fairly be attributed to the fact that the people do not bolt from apprehensions of segregation, but they remain in their houses. There is no terrifying cause, or influence, which would induce them to bolt from one part to the other.

24,972. Have you been able to compare the manner in which the country-side in the neighbourhood of Mysore city has been effected by plague, as compared with the country-side in the neighbourhood of Bangalore city and Bangalore Civil and Military Station?—On this point, my information is necessarily derived from the Darbar, but the authorities—and I believe their reports are fairly accurate—assure me that the country round the Mysore city is very little infected as compared with the country around Bangalore.

24,973. I understand you to say that in both cases the reports come from Darbar?—In both cases, certainly.

24,974. So that there would be the same element of error?—Yes, certainly.

24,975. Do you think that the fact that the neighbourhood of Mysore has been less infected than the neighbourhood of Bangalore could be accounted for by the fact that the villagers now know about plague, and keep strangers out of their villages?—Yes, I think that may have something to do with it, and it is also possible that people may have camped out more than they could in the time of the Bangalore epidemic, when we had almost continuous rain.

24,976. But you would not exclude the possibility of benefit having resulted from fewer people having left Mysore?—I think that is the main cause.

24,977. Could you give us an estimate of the number of people that left Mysore?—I believe it is impossible to do that, because no census was taken of Mysore at the commencement of the plague, and the ward registration of the inhabitants was very defective. They do not know themselves, but looking at the town as I have frequently seen it of late, it did not strike me that it had emptied to any appreciable extent.

24,978. Was there any panic, or any serious disturbance of the ordinary business of the people in Mysore?—There was no panic and no disturbance whatever.

24,979. Was there any disturbance of business in Bangalore city?—Most decidedly. The food supplies ran out almost entirely, so much so that grain was almost selling at famine rates, and we had, for the Civil and Military Station at all events, to improvise an agency for importing grain and firewood, and foodstuffs for the people.

24,980. Are you of opinion that it is not possible, at the present moment, to pronounce authoritatively on the relative merits of the systems adopted in Bangalore and Mysore respectively?—That is so, but at the same time I think there can be no question that the evidence, so far as it is available, points unmistakably in favour of the Mysore voluntary system.

24,981. Would you, as the time goes on, send us reports as to the progress?—Certainly. I may mention that Mr. Cadell is my Assistant, and he has various figures to give, and anything we can supply we will.

24,982. (*Dr. Ruffer.*) Are the sanitary conditions in Mysore the same as in Bangalore?—If anything, the sanitary conditions in Mysore are worse than in Bangalore.

24,983. You mean that the people are more crowded together?—I think the town stands lower, it is more waterlogged, and it is an older city.

24,984. Is there more overcrowding than there is in Bangalore?—I should think that it is about the same; there is very little to choose in that respect; but, as regards the appearance of the town, and the position, I think I should say that Mysore was distinctly more insanitary.

24,985. Are they the same class of people?—Yes, practically.

24,986. Will you tell us how many cases have been treated in their houses, and how many in the hospital?—I did not come to Bombay prepared to give evidence, and I have no figures. Mr. Cadell has them.

24,987. Can you tell me whether the mortality is greater amongst the people who have been treated in their own houses, or amongst the people in hospitals?—That I cannot tell. If Mr. Cadell has not got these figures, it will be quite easy to get them.

24,988. You say that the houses were disinfected as soon as a patient was reported?—That I believe is the order.

24,989. Is the house disinfected again after death?—I am not sure about that.

24,990. Do you know how the house is disinfected?—Yes, I watched it being done. That is perhaps a rather weak point in the Mysore work; I do not think the disinfection is under sufficiently competent supervision. This, however, is a detail in working.

24,991. Who is in charge of the disinfection?—They have a European of no particular status.

24,992. A medical man?—No.

24,993. (*Mr. Cumine.*) Do you find that leaving a patient in his house leads to many of the other members of the family catching the disease?—I asked them in Mysore particularly to record facts about this, because I recognised that it was one of the most important points; they have done so to some extent, and Mr. Cadell will produce the figures.

24,994. (*The President.*) When did the plague commence in Mysore?—I do not know the exact date of the first case, but I think it was in November or December. Mr. Cadell has the figures of when the cases began.

24,995. From the commencement, the system which you have just described has been in operation?—Yes.

24,996. The so-called voluntary system?—Yes.

24,997. During this time, has plague to your knowledge steadily increased in Mysore?—No, it has fluctuated. It increased up to a certain point and now the tendency is a downward one. There is no marked rapid fall, but the last telegrams I got stated that the total mortality was 26 per diem.

24,998. You cannot distinguish the plague cases?—Yes, but I believe in a town like that, that the only safeguard is the total mortality.

24,999. What do you estimate the plague deaths at?—In these figures that are given me, the total mortality being, say 26, the plague deaths would be about 19 per diem, the normal mortality being about six or seven.

25,000. We had the opportunity of seeing the houses when we were in Bangalore; are the houses in Mysore about the same?—Yes.

25,001. There are a good many one-chambered houses?—Yes, very rarely more than one storey; but they are easier to disinfect. I do not know whether you remember that in Bangalore there are many flat roofs, in Mysore they are nearly all gable roofs and tiles.

25,002. How does that facilitate the disinfection?—Because you can take off the roofs.

25,003. In disinfection you include the removal of tiles?—Yes, and letting in the sun and air.

25,004. Air and sun disinfection, as well as chemical disinfection?—Yes.

25,005. I do not quite understand how this disinfection is effected in one-roomed houses when the patient is in the house?—I mean one storey houses: the houses have small rooms, and as a rule they are one-storeyed.

25,006. The floor, I suppose, is of the same nature as in Bangalore—mud?—Yes, mostly mud with cow-dung.

25,007. The houses are usually quite dark?—Yes, certainly.

25,008. You, I understand, are not in a position as yet to give any definite opinion as to the success of this system?—Not definitely, except intermediately that everything points at present to a favourable conclusion.

25,009. It has gone on since October or November?—Not so early as that. I think the first cases were in December. All the first cases were imported, but I think the first indigenous cases were in December.

25,010. On the whole it is on the decline?—Yes, I think there is a downward tendency.

(Witness withdrew.)

Mr. P. R. Cadell, I.C.S.
14 Mar. 1899.

Mr. P. R. CADELL, I.C.S., recalled and further examined.

25,011. (*The President.*) We wish some further information from you with regard to Bangalore City?—Yes.

25,012. (*Mr. Hewett.*) You have some figures with regard to the Civil and Military Station which will supplement Colonel Robertson's evidence at Bangalore Will you kindly put them in?—Yes.

25,013. First of all, will you state what they are?—Firstly, the progress of disease by wards in Bangalore and Mysore.

STATEMENT I.

BANGALORE CITY.

NUMBER of DEATHS from all Causes by WARDS from 12th August 1898 to 28th February 1899.

Ward Number.	Population.	Total Mortality.	Percentage to Population.	Ratio per Mille per Annum.
Ward I.	20,663	1,545	7·5	138
Ward II.	27,095	2,670	9·9	182
Ward III.	11,843	1,090	9·2	169
Ward IV.	20,684	1,793	8·7	160
Total	80,285	7,098	8·8	163

BANGALORE, CIVIL AND MILITARY STATION.

PROGRESS of the DISEASE by WARDS from 15th September to 28th February 1899.

Circle Number.	Population.	Plague Attacks.	Percentage to Population.	Plague Deaths.	Percentage to Population.	Total Mortality.	Percentage to Population.	Ratio per Mille per Annum.
I.	4,774	49	1	37	·8	60	1·3	27
II.	16,196	610	3·7	512	3·1	1,102	6·8	148

XIV.	4,120	48	1·1	25	·5	55	1·3	27
Outside limits and unknown.	—	82	—	46	—	46	—	—
Total	100,081	4,060	4	3,298	3·3	6,130	6·1	133

MYSORE CITY.

PROGRESS of the DISEASE by WARDS from 1st October 1898 to 28th February 1898.

Ward Number.	Population.	Plague Attacks.	Percentage to Population.	Plague Deaths.	Percentage to Population.	Total Mortality.	Percentage to Population.	Ratio per Mille per Annum.
1	33,251	1,356	4·1	1,074	3·2	2,155	6·5	156
2	31,187	470	1·5	387	1·2	977	3·1	75·2
3	9,610	104	1·1	53	·6	76	·8	19·
Total	74,048	1,930	2·6	1,519	2	3,208	4·3	104

NOTE.—No death from any cause is recorded from Ward III. from 1st October to 20th January, which suggests some inaccuracy and is being inquired into.

The deaths in Ward III., which was only constituted on 18th January, have, up to that time, been recorded under Wards I. and II.

25,014. Have you returns of deaths among races?—Yes.

25,015. Will you put them in, all three—for Bangalore City, the Civil and Military Station, and Mysore?—Yes.

STATEMENT II.

BANGALORE CITY.

NUMBER of DEATHS from all Causes by RACES from 12th August 1898 to 28th February 1899.

	Population.	Total Mortality.	Percentage to Population.	Ratio per Mille per Annum.
Hindus and others	67,388	5,280	7·8	145
Muhammadans	10,472	1,671	15·9	294
Native Christians	2,425	147	6·1	112
Total	80,285	7,098	8·8	163

BANGALORE, CIVIL AND MILITARY STATION.

MORTALITY by RACES from 15th September to 28th February 1899.

——	Population.	Plague Attacks.	Percentage to Population.	Plague Deaths.	Percentage to Population.	Total Mortality.	Percentage to Population.	Ratio per Mille per Annum.
Europeans - -	4,985	18	·3	12	·2	37	·74	16
Eurasians - - -	2,649	47	1·7	35	1·3	77	2·9	63
Native Christians -	10,268	414	4·4	320	3·1	517	5	109
Muhammadans - -	23,892	871	3 6	789	3·3	1,881	7·9	172
Hindus and others -	58,287	2,650	4·5	2,142	3·7	3,611	6·2	135
Total - -	100,081	4,000	4	3,298	3·3	6,130	6·1	133

MYSORE CITY.

SPREAD of the DISEASE by RACES up to 28th February 1899, from 1st October 1898.

——	Population.	Plague Attacks.	Percentage to Population.	Plague Deaths.	Percentage to Population.	Total Mortality.	Percentage to Population.	Ratio per Mille per Annum.
Hindus and others -	58,741	1,345	2·3	1,026	1·7	2,223	3·8	91
Muhammadans - -	15,307	585	3·8	493	3·2	985	6·4	155
Total - -	74,048	1,930	2·6	1,519	2	3,208	4·3	104

25,016. Is there any point you would like to call our attention to with regard to those three returns?—As regards the races in all three cities, the Muhammadans suffered much the most severely.

25,017. Are the Muhammadans in all those three towns in a depressed condition?—Yes, they are all poor—very much poorer than the Muhammadans elsewhere; and they are much more crowded, I think, than the Muhammadans elsewhere in their houses.

25,018. When you say the Muhammadans have suffered more than other classes, I suppose you are deducing your conclusion from the total mortality rather than from the number of recorded plague attacks?—From the total mortality.

25,019. On the ground that the difference between the normal mortality and the mortality during the plague outbreak is practically attributable to plague?—For Mysore City and Bangalore Civil and Military Station I have the plague figures as well as the total mortality. In the Civil and Military Station the Muhammadans, from recorded plague deaths, suffered less than the Hindus; but their total mortality was considerably higher. In Mysore, both from the recorded plague deaths and the total percentage of the population, it was higher than in the Hindus.

25,020. And Bangalore City?—In Bangalore City the record of deaths from plague was so inaccurate that I could not get the figures. I have got the total mortality.

25,021. Do the Muhammadans in those three towns live in more overcrowded houses than the other portions of the population?—No; I could not say that.

25,022. Have you any other reason which you can offer for their being attacked more than the Hindus?—Except that there was greater concealment in the Civil and Military Station among the Muhammadans, and where, in the end, the Hindus have been got to report the cases early, the Muhammadans never did it in the Civil and Military Station. A much smaller proportion of the Muhammadans, also, underwent inoculation.

25,023. You think the fact that they had plague cases and that no precautions were taken may have increased the plague mortality among them?—I think so.

25,024. The next statement you put in is one relating to the hospital figures?—Yes. The statements with regard to Bangalore City, Civil and Military Station, and Mysore City, are as follow:—

STATEMENT III.

HOSPITAL FIGURES: TOTAL ADMISSIONS.

Hospital.	Admissions.	Discharges.	Deaths.	Percentage of Mortality.	Remaining.
Bangalore City - -	2,131	709	1,422	66·7	—
Civil and Military Station:—					
North Camp - -	940	336	596	63·4	8
South Camp - -	768	306	462	60·2	—
Total - -	1,708	642	1,058	61·9	8
Mysore - - -	206	20	101	49	85

NOTE.—The hospital figures for Mysore are up to the 28th February, and for the Civil and Military Station up to the 3rd of March, 1899.

25,025. In the figures for the Plague Hospital of Mysore City, you show the total admissions to the hospital to have been 206; could you give us any estimate as to the number of persons suffering from plague who were treated in their own houses in Mysore?—No, not those who were treated separately from those who died without treatment.

25,026. You cannot give any approximate estimate?—No, I am afraid not, as treatment was voluntary. The total mortality in the houses was, of course, higher.

25,027. Then you have a statement of hospital figures as regards the inoculates?—Yes. It is as follows:—

STATEMENT IIIA.

HOSPITAL FIGURES for INOCULATES.

——	Admissions.	Deaths.	Discharges or Convalescent.	Percentage of Mortality.
Bangalore City -	57	31	26	54·4
Civil and Military Station:—				
North Camp	87	24	63	27·6
South Camp	41	12	29	29·3
Total -	128	36	92	28·1
Mysore - -	26	9	Not shown	34·6

NOTE.—The figures for the Civil and Military Station are up to the 3rd of March, and those for Mysore up to the 28th of February, 1899. The figures for the Military Hospitals are contained in separate statements relating to the Military.

Mr. P. R. Cadell, I.C.S.
14 Mar. 1899.

25,028. And you have a statement of the number of cases of plague which occurred amongst the contacts?—Yes, for all three. The proportion of contacts in Mysore, where the contacts were all voluntary, was higher than in the Civil and Military Station.

STATEMENT IIIB.

ADMISSIONS to CONTACT CAMP.

—	Admitted.	Developed Plague.	Percentage developing Plague.	Died from other Causes.
Bangalore City -	3,960	238	6	—
Civil and Military Station:—				
North Camp	1,527	50	3·3	3
South Camp	887	25	2·8	—
Total -	2,414	75	3·1	3
Mysore City -	452	27	6	—

NOTE.—In the earlier stage of the epidemic, contacts in the Civil and Military Station were allowed to go out to their work. Many absconded, and the above numbers were, therefore, not all detained for ten days.

25,029. The camp was reserved for contacts in Mysore; it was not a health camp?—No, entirely a contact camp.

25,030. Have you any information to give us as to how long after the contacts came into camp they developed plague?—I have figures for the Civil and Military Station only. They are:—

Number developing plague—

On first day after arrival in camp -	26
,, second ,, ,, -	16
,, third ,, ,, -	5
,, fourth ,, ,, -	5
,, fifth ,, ,, -	8
,, sixth ,, ,, -	1
,, seventh ,, ,, -	3
,, eighth ,, ,, -	1
,, ninth ,, ,, -	7
,, tenth ,, ,, -	3
	75

25,031. Have you got the number of houses in which more than one seizure has been recorded?—It is as follows in Mysore:—

NUMBER of HOUSES from which more than ONE SEIZURE has been recorded.

In 76 houses there were	2	attacks.
,, 26 ,, ,,	3	,,
,, 4 ,, ,,	4	,,
,, 6 ,, ,,	5	,,
,, 4 ,, ,,	6	,,
,, 2 ,, ,,	7	,,
,, 1 ,, ,,	10	,,
119		

In Bangalore City there was more than one seizure in 297 houses, but the exact number in each is not known.

25,032. In all the other houses in Mysore in which plague cases occurred, was there only one attack?—There could have been only one attack.

25,033. Do these figures refer only to cases definitely found to be due to plague?—Yes.

25,034. Have you a statement with regard to the number of inoculations performed in Bangalore City, Bangalore Civil and Military Station, and Mysore?—Yes, as follows:—

STATEMENT IV.

BANGALORE CITY.

SHOWING NUMBER of INOCULATIONS performed from 2nd September 1898 to 28th February 1899.

—	Number of Inoculations.	Remarks.
Week ending 8th September 1898	81	
,, 15th ,, ,,	241	
,, 22nd ,, ,,	328	
,, 29th ,, ,,	4,212	
,, 6th October ,,	4,384	
,, 13th ,, ,,	1,280	
,, 20th ,, ,,	1,108	
,, 27th ,, ,,	1,285	
,, 4th November ,,	2,667	
,, 11th ,, ,,	1,385	
,, 18th ,, ,,	2,134

Total - -	118	98	83	84	71·2	62	73·8

25,035. You have endeavoured to get the information asked for from Col. Robertson with regard to the incidence of plague among the inoculated and uninoculated?—Yes.

25,036. Have you got that only for the Civil and Military Station?—We have only that accurately for the Civil and Military Station.

25,037. You put in other figures?—I have put them here for what they are worth, but for Mysore city they are inaccurate so far as regards the examination of bodies, and I would not vouch for them. The statement attached for the Civil and Military Station shows that of the cases actually seen and pronounced to be plague, 10·8 of the seizures and 9·4 of the deaths were among inoculated persons, against 85·1, or 85·5 respectively among the uninoculated; this is considerably lower than the proportion of the inoculated to the uninoculated population:—

STATEMENT No. V.

CIVIL AND MILITARY STATION.

PROPORTION of INOCULATED PERSONS ATTACKED to TOTAL NUMBER of ATTACKS and DEATHS.

Number of Plague Cases seen by Government Medical Officers and found to be or not to be inoculated.								Number of Cases seen by Hakims and pronounced to be plague.								Number of Bodies buried without Permit, and counted as Plague.
No. of Cases seen by Govern- Medical Officers.		No. of these found to be Inoculated.		No. of these found not to be Inoculated.		No. doubtful or Unknown.		No. of Cases seen by Hakims and pronounced Plague.		No. of these found to be Inoculated.		No. of these found not to be Inoculated.		No. of these Doubtful or Unknown.		
Attacks.	Deaths.	Attacks.	Deaths.	Attacks.	Deaths.	Attacks.	Deaths.	Attacks.	Deaths.	Attacks.	Deaths.	Attacks.	Deaths.	Attacks.	Deaths.	
3,473	2,772	374	260	2,961	2,374	138	138	9	9	2	2	3	3	4	4	516

The remaining persons who died between 15th September and 28th February, were either seen by Medical Officers and certified not to have died of plague, or were seen by Hakims and Baids and pronounced not to have died of plague, or were buried without certificate, before the certificate rules came into force.

—	Number seen and pronounced to be Plague.	Percentage inoculated.	Percentage not inoculated.	Percentage unknown.
Attacks -	3,482	10·8	85·1	4·1
Deaths	2,781	9·4	85·5	5·1

25,038. Could you tell us how the fact of a person being inoculated or uninoculated was ascertained for the purpose of these returns?—Inquiries were always made in the household, and if possible a certificate was recovered.

25,039. Do you think that there is any margin of error by reason of any disposition of the people to retain the certificate?—I think there is a slight margin of error.

25,040. But you would not attach any material importance to it?—No. Inquiry was made on that point, and the medical officer said that they only found rare instances in which there was suspected transference of the certificates.

25,041. Can you tell us when the first indigenous case of plague took place in Mysore?—It was on the 26th November.

25,042. Do you know whether there was in Mysore any mortality among rats before cases began to occur?—I do not know.

25,043. Is Mysore city dirtier or cleaner than the town of Bangalore?—It is dirtier and generally more unhealthy. Amongst those who know them well, there is only one opinion, that Mysore is ordinarily a far dirtier and more unhealthy town than Bangalore. Col. Benson says the difference between the healths of the jails in each place is striking. It is true that this year there has been singularly little malarial fever in Mysore jail: but in general the town is extremely malarial, lying in a hollow, with no fall for its sewage. Mr. Architrao, Civil Surgeon of Mysore, writes, "The town is incom- "parably more filthy than the pettah of Bangalore. "In places like old Agrahar the houses are inde- "scribably damp for the greater part of the year."

25,044. Has past experience shown that epidemics of cholera attacked both places alike?—As regards liabilities to epidemics, both Bangalore, so far at least as the Civil and Military Station is concerned, and Mysore have been subject to visits of cholera, though in Mysore there has been no epidemic since 1891. Formerly it was more liable to cholera.

25,045. At the time of the year when plague broke out in Bangalore there was much more difficulty in dealing with the disease than at the time it broke out in Mysore, was there not?—Yes. In respect to climatic conditions it cannot be doubted that the plague attacked Bangalore

Mr. P. R. Cadell, I.C.S.
14 Mar. 1899.

at the more unfortunate period of the year. Both in October and November there was heavy rain, and this not only hampered all active operations carried out by the officials, but drove the people into their houses, just at the beginning of the cold weather. In Mysore, the disease has spread at a much drier season; the weather has become, for the Province, warm, and the season of the year is approaching in which the plague has, I think, usually dropped in Bombay.

25,046. When was this evil effect of climate most apparent as regards the epidemic in the Civil and Military Station?—From about the 11th to the 20th November in the Civil and Military Station.

25,047. Then it would not have been operating at the time that plague was at its worst in Bangalore city?—I could not say about Bangalore city from personal knowledge. There was rain in October, too. I cannot say what the exact effect was on the plague operations.

25,048. Do you think between the 22nd October and the 4th November, from what you have heard, that the operations in Bangalore city were seriously prejudiced by the rains at that time?—Yes, I was told so. I put in a statement of the rainfall, as follows:—

STATEMENT of RAINFALL in BANGALORE.

No rain in January.

25,049. When the outbreak took place in Mysore, to what extent had inoculation been resorted to there?—By the end of November in Mysore 10,600 people had been inoculated, and by the end of December 26,000 people—over one-third of the population—had been inoculated.

25,050. And in Bangalore city and in Bangalore Civil and Military Station the people were not inoculated until plague was among them, were they?—No. At the end of October in the Civil and Military Station, by which time the plague had got very bad, there were only 12,000 persons inoculated: at the end of November 20,000 were inoculated. By that time the disease had begun to decrease so that less than one-fourth of the non-military population was inoculated before the disease turned.

25,051. You say in the précis of your evidence: "It "may be taken, I think, that Bangalore, both the "Civil and Military Station and city, underwent an "abnormally severe attack." What do you mean by that, precisely?—That there were a very large number of cases. I do not go into the causes of it at all, as I cannot say whether one type was more severe than the other.

25,052. You do not mean to say that the conditions of the epidemic were different?—No, I say that the results were different.

25,053. Will you kindly tell us the state of plague at present, first of all in Mysore and secondly in Bangalore Civil and Military Station?—In the Civil and Military Station it is practically extinct. Last week we had only five indigenous cases and the week before only four. They are all sporadic cases. With the exception of these sporadic cases plague is extinct.

25,054. Can you give us the total mortality of Bangalore city, the Civil and Military Station, and of Mysore city respectively up to date, from the beginning of the outbreaks?—In Bangalore city there have been 2,652 recorded deaths from plague. The total mortality has been 7,115, and taking an estimated daily death rate of seven from the normal causes, the excess over that normal is 6,016. In the Civil and Military Station there have been 3,306 recorded deaths from plague, a total mortality of 6,192, and taking the normal average of 9 per diem the excess over the normal since the beginning of the outbreak has been 4,779. In Mysore city there have been 1,592 deaths from plague. The total mortality has been 3,301. Taking the normal from other causes of 7 per diem, the excess over the normal is 2,202. So, roughly, it may be taken that plague mortality in Bangalore city was 6,000, in the Civil and Military Station it was 4,800, and in Mysore 2,200 up to date.

25,055. I believe you have prepared charts which show in respect to Bangalore city and Bangalore Civil and Military Station the normal mortality, the total mortality, and the plague mortality during both epidemics. And one for Mysore city shows the total recorded mortality and the total plague mortality?—Yes.*

25,056. Perhaps you will complete these two charts as to Mysore and Bangalore Civil and Military Station and send them to us by the end of April?—Yes.*

25,057. I believe you were at Bangalore Civil and Military Station when the disease was there in epidemic form?—Yes.

25,058. Did you observe any difference in the attitude of the people in the Bangalore Civil and Military Station and Mysore?—The difference has been very striking in the way the Mysore people have freely reported the cases. As far as we know they have not tried to remove the sick from the town or from the houses, and they have reported very freely indeed. In Bangalore Civil and Military Station they did not report until the very end and only after great compulsion. They also removed the sick to a very considerable extent.

25,059. Has the result been that you found plague at a much earlier stage in Mysore?—I believe so.

25,060. When you found a patient suffering from plague in Mysore, I understand that he was given the option of remaining in his house or going to the hospital?—Yes.

25,061. Were the patients urged to go to hospital as a rule?—They have been advised to go.

25,062. But the result has been that only a comparatively small number of the sick have gone?—Yes, comparatively few.

25,063. Supposing you found a plague patient sick in his house, what did you do with the people who were in the house with him?—If they agreed to allow the patient to remain in the house, nothing was done to the other people.

25,064. What was done to the house?—Nothing was done.

25,065. No disinfection?—No. The rule was that a house was not to be disinfected until the patient either died or recovered. As a matter of fact Col. Benson tells me that the houses have generally been disinfected excepting the room in which the patient has been living.

25,066. (*The President.*) At the commencement or afterwards?—Immediately.

25,067. (*Mr. Hewett.*) The room in which the patient was suffering was left alone till the patient either recovered or died?—Yes.

* *See* App. No. LXXI. (i) to (iv) in this Volume. The charts have not been completed beyond the beginning of March.

25,068. The whole of the family were permitted to visit him, I suppose, where he was lying?—Yes.

25,069. Does the patient as a rule lie on the floor or on a bed?—In Mysore, on the floor.

25,070. Have you observed whether the plague has moved more rapidly about different parts of Mysore city than it did about the Civil and Military Station at Bangalore?—It moved very much more slowly in Mysore.

25,071. To what do you attribute that?—To the people not being disturbed and not moving. I do not think there has been any other cause, unless the disease can be said to have been, of itself, more virulent in Bangalore.

25,072. Has there been any panic in Mysore?—No, none.

25,073. And the ordinary business has been conducted throughout the epidemic?—Yes, throughout the epidemic.

25,074. Has there been any exodus of the people to outlying parts of the country?—A large number have gone—about 20,000—but not nearly to the same extent as in Bangalore city.

25,075. Have you had any opportunity of ascertaining whether the neighbourhood of Mysore has been infected as much as Bangalore?—It has been far less affected. In Bangalore the whole of the surrounding tálukas were highly infected.

25,076. Do you think that the fact that the neighbourhood of Mysore has not been so badly infected may to a certain extent be accounted for by the villagers knowing more about the measures?—Yes, and in being more careful in keeping strangers out.

25,077. Do you think that this is the only circumstance which has affected the extent of the infection near Mysore?—There is the fact of their camping out. In Mysore, they certainly did learn that lesson thoroughly. They camped out very early on the appearance of the disease. I think something must be assigned to the fact, that far fewer sick people were taken out than in the case of Bangalore.

25,078. Have you observed anything else with reference to the relative treatment in hospital in Bangalore, and in the Civil and Military Station and Mysore city?—There are so many still remaining under treatment in Mysore hospital that I do not think it is safe to draw any deductions. The figures are so far more satisfactory in Mysore. In Mysore the mortality has been 49 per cent. so far; whereas in the Civil and Military Station the mortality was 61 per cent., and in Bangalore 66 per cent.; but, of course, the numbers in the Mysore hospital have been smaller.

25,079. Have you any reason for thinking that the voluntary system, as adopted in Mysore, will, in the long run, lead to a greater extension of plague in Mysore city?—I think it is inevitable it will spread over the whole city. It is spreading. It is attacking quarters which have hitherto been free. I think it is inevitable that it must go all over the town.

25,080. Do you think that it is likely that it will be more severe than if the system adopted in Bangalore city and Civil and Military Station were adopted?—I do not think there will be as high a mortality as in Bangalore.

25,081. I am speaking of the city?—Yes.

25,082. I understand you to say that apart from the city itself, the result of the voluntary system will be, to a certain extent, that the neighbourhood will suffer less severely than it did at Bangalore?—Yes, so far as we can say at present.

25,083. That would rather tend to show that the disease is less likely to extend from a place in which the voluntary system is at work?—Yes.

25,084. Do you think that the disinfection which has been carried out at Mysore has been effectively carried out?—I do not think so. There has been very little European supervision in Mysore—only one or two subordinates.

25,085. Do you think that disinfection under a system, such as you have had in Mysore, might have been properly carried out if you had had proper supervision?—I do not see how it could be. According to the rule, the people may object to their houses being disinfected until the patient has died or recovered. It gives infection a very long time to spread.

25,086. Why do the people object to a house being disinfected before the patient has died?—It is the Darbar's rule that the house need not be disinfected until then. Even if the house was disinfected, with the exception of the room in which the patient was lying, there would obviously be danger of fresh infection to the house as long as the patient remained ill in it.

25,087. Have the people of Mysore displayed any objection to disinfection?—I believe they did at first, but to a very small extent.

25,088. Has the effect of this system been that people have been in better heart during the epidemic?—I think so. I saw a very marked difference in the demeanour of the people in Mysore than in Bangalore.

25,089. Has this voluntary system caused greater or less expense than the one adopted in the Civil and Military Station?—Far less expense. The system of the Civil and Military Station was extremely expensive, whereas in Mysore, there was very little expense indeed.

25,090. In addition to the other evils which existed in Bangalore Civil and Military Station, was there any difficulty owing to the staff running away?—The sweepers in the early part of the epidemic ran away—they struck.

25,091. Did you find any difficulty of that sort in Mysore?—No, but that could have had nothing to do with the system, except as to the results—that the extent of the disease and the high mortality might make the sweepers strike. The sweepers themselves would not be influenced by the plague measures.

25,092. Were they influenced particularly by fear of death?—Yes, and by the desire to earn higher wages—reasons which would cause an ordinary strike.

25,093. Do you think that it would be possible to combine the evacuation of infected quarters with the voluntary system?—I think so. The officers of Mysore say it would have been impossible in Mysore without disturbing the people unduly. I think it would be possible in a second epidemic, and I think in most places it would be possible to persuade the people in a first outbreak.

25,094. Would you explain exactly what you mean by a combination of the two—how would you combine the systems?—By combination I mean telling the people that they must leave an infected quarter, and providing huts for them, and saying they must go there; and as far as the sick are concerned, taking their sick with them, and having no segregation amongst them of any contacts, or even of the sick, except what they carried out themselves—simply making the people leave the infected quarter, and go to another place; otherwise leaving them entirely at liberty, though, if necessary, forbidding them to go to adjoining villages.

25,095. That is to say, under such a system there would be no compulsion as regards going to hospital, and no compulsion as regards being placed in the contact camp?—That is so.

25,096. (*Dr. Ruffer.*) How did you disinfect the houses in Mysore?—The actual work in Mysore was entirely under the Darbar—the State officials. I cannot talk of the actual work.

25,097. How was it done?—The disinfection was done on the same system as it was done in Bangalore.

25,098. Did you provide rules for disinfection?—Yes; the Mysore State had rules.

25,099. Can you put those in?—Yes, they are as follows:—

"10. *Disinfection.*—When it is provided in these rules, or in any others, which are or may be in force in the cities of Bangalore and Mysore that disinfection may be employed, disinfection as follows, as often as seems to him necessary, may be ordered by any plague authority, unless where otherwise provided:—

"*Of the Person.*—In a bathing tub, with Jeyes' fluid or carbolic acid, strength, 1 in 100.

"*Of Travellers' Bundles.*—(1) If specially ordered by the President, or any officer deputed for the purpose, to be opened out and steamed for 20 minutes by steam pressure of 20 lbs. and temperature 250° or (2) otherwise, to be treated as below.

"*Of Clothes, Silks, &c.*—To be exposed first one side then the other, for eight hours in a strong sun.

"*Other Cloths, &c.*—In perchloride of mercury, 1 in 1,000.

Mr. P. R. Cadell, I.C.S.

14 Mar. 1899.

"*Of an infected House.*—If its value is Rs.100 or less, and there is no danger of the fire spreading, it may be burnt. Otherwise, if a plague authority so directs, it may be unroofed and treated as provided in the next paragraph, after removal of all surrounding obstructions (walls, huts, sheds, pandals, &c.), to ensure a complete perflation of air.

"*Of Houses in an infected Area.*—Each house shall be opened to light and air in its dark rooms. Infected things of small value, such as bedding, cots, &c., may be burnt. Everything else, as well as the entire interior of the house, including the floor, shall be sprayed or sprinkled with perchloride of mercury. The floor of the rooms used by the sick person shall, if of earth, be dug out to a depth of two inches, and removed to a spot well away from habitations, and thoroughly burnt. Rubbish shall be burnt or carted away. Then the exterior and interior of the house shall be limewashed, chloride of lime being mixed with the limewash.

"*Of other Places and Spaces in such an Area.*—As any plague authority may direct."

25,100. What do you mean by saying that the cases in Bangalore now are sporadic?—I mean scattered and unconnected with each other. The five indigenous cases we had last week occurred in five different quarters of the town. There was not any particularly infected locality, and the week before, similarly, six cases were found in five different quarters.

25,101. Did you have corpse inspecti on in Mysore?—Yes, there has been corpse inspection.

25,102. Has every dead body been seen?—Yes, after the 22nd January.

25,103. Are you inspecting all the bodies now?—I believe so, in Mysore and in the Civil and Military Station they are now inspecting all the bodies.

25,104. Do you think there was much difficulty in examining the bodies of women?—I cannot say to what extent it was carried out in Mysore, whether it was strictly carried out or not. In the Civil and Military Station, all the bodies of women have been examined by females.

25,105. Do you know whether there have been any disturbances owing to corpse inspection?—No disturbance.

25,106. Did you give any special advantages to inoculated people?—Not in Mysore, because there were no special advantages to give to anybody, as there were no restrictions.

25,107. Have you any knowledge of inoculated people leaving the place?—They undoubtedly did so in large numbers in Bangalore.

25,108. I am speaking of Mysore?—In Mysore, no. I think a certain number would get inoculated because they know inoculated people have greater privileges on the railway.

25,109. You think that people get inoculated to go away?—Yes, a certain number.

25,110. That was the case in Bangalore was it not?—Yes.

25,111. A great many inoculated people did leave Bangalore, did they not?—Yes. In Bangalore city, out of 28,000 inoculates 12,000 are stated to have left.

25,112. Will you turn to Statement No. IV. about Mysore city? When you say the number of inoculates attacked, I suppose you mean the number you know of?—Yes.

25,113. There may have been more than that number attacked?—I do not think there is any reason to suppose there may have been many more, because inquiry was always made in the case of death.

25,114. There may have been many more attacked than were registered, might there not?—Not many, in Mysore they got the reports of the attacks, and they would always inquire.

25,115. You think the reports were accurate?—Yes, the people had no reason for misleading in Mysore.

25,116. You say "number of inoculates, 118, number "verified by comparison certificates, 98"?—Yes.

25,117. That means, that in 20 cases you could not find the certificate?—Either the certificate could not be found or the entry could not be found in the register.

25,118. So that there is a possibility of 17 per cent. of people having died who were not inoculated, or that the certificates had disappeared, or had been kept by the people themselves?—Yes, or that the inoculation had been done in all cases, and that the register had not been properly kept.

25,119. So that there is a possibility of an error of 17 per cent.?—Yes.

25,120. (*The President.*) With regard to the Statement No. I. referring to Mysore city, how do you account for the very large number of cases in Ward No. 1 relatively to other wards?—I think the return is unreliable, because the deaths in the third ward were not separately entered till the 13th January. Therefore, I think a great number of them may have been entered under the first ward.

25,121. The figures are not altogether reliable?—No, but the disease has been worse in the first ward. It started there.

25,122. It was worse there?—It has been actually worst there. I do not think the ward was worse than the other parts of the town from a sanitary point of view.

25,123. It only commenced there?—Yes, it got a footing there.

25,124. You have already expressed the opinion that Mysore is, on the whole, a dirtier place than Bangalore?—Yes.

25,125. Is there any difference with regard to overcrowding or the character of the houses?—The back streets are generally narrow and dirty in Mysore. I cannot speak of the overcrowding.

25,126. There is a larger population, I suppose, in a smaller space?—Yes.

25,127. Overcrowding is not only in the houses but in the area, I suppose?—In the area. I do not know about overcrowding in the houses. The area is smaller.

25,128. I see that you have made some reference to cholera having practically disappeared from Mysore since 1891?—Yes.

25,129. Can you tell us what kind of water supply there is in Mysore?—Cholera has disappeared since the new water supply was introduced.

25,130. Why do you think disinfection is quite useless under this voluntary system?—Because there is no certainty of doing it in time, and it can very likely only be done several days after the infection has had a start.

25,131. Therefore, if the voluntary system has any advantage, it is independent of any advantage gained by disinfection?—That is so.

25,132. You do not think it quite fair to compare the conditions in Bangalore so far as plague is concerned, with the conditions in Mysore, at present?—I think it would be dangerous to draw too strict a comparison between the two places.

25,133. Experience may, for anything you know, show that it would become much worse in Mysore than it has been even in Bangalore?—Yes, it might; but it does not seem likely to do so.

25,134. What was the great difference in the system pursued in Bangalore compared with the system followed in Mysore?—In Bangalore there was compulsory segregation—the sick person was always taken off to the hospital at once, and the persons living in the same house were removed to the segregation camp for ten days. In Mysore, no person has been removed to hospital except of their own consent, or with that of their relatives, and taking people to the segregation camp has been entirely voluntary. No one has been obliged to go there who did not wish to go.

25,135. Therefore, Mysore had not the advantages of so-called evacuation?—No, there was no evacuation in Mysore.

25,136. Therefore, there is no comparison to be made between Mysore and Bangalore with regard to evacuation in one and its absence in the other?—With regard to evacuation in large areas, in neither; but in Bangalore Civil and Military Station there was evacuation in some small areas, but that was subsidiary to other plague measures.

25,137. But judging between the native towns in both cases?—There has been no evacuation on a large scale in either.

25,138. I think you wish to put in some further tables which you have prepared, regarding the military population, and to make a statement with regard to the number of uninoculated people?—Yes, the statements are as follows:—

Mr. P. R. Cadell, I.C.S.

STATEMENT IV.—EVACUATION and SEGREGATION.

The following Corps segregated their contacts only:—

2nd Madras Lancers.
1st Madras Pioneers.
17th Madras Infantry.
Followers J. Battery, R.H.A.
Commissariat and Transport Followers.

The following evacuated their lines:—

—	Date.	Cases after Evacuation.
Q. O. Sappers and Miners - - -	16th November -	10*
Followers, 4th Q. O. Hussars - - -	17th November - -	3
Followers, 21st F.B., R.A. - -	12th December -	3†
„ 25th F.B., R.A. - - -	10th December - -	3

The numbers of the contacts segregated are not known. Only two contacts appear to have developed plague, but it is not certain whether this is the whole number.

* The Sappers were encamped on their Parade Ground, close to their old lines, and to infected quarters.
† Two of these were officers' syces who lived partly at the bungalows.

The exact number of the military population is not known, as there are always a certain number of unauthorised inhabitants of the lines. Taking it, however, at the figure of the Census of 1891, namely 15,133, the following figures may be taken:—

Total Population of the Station by Census of 1891.	Estimated Deaths from Plague to end of February.	Percentage of Mortality to Population.
100,081	4,779	4·77

Total Civil Population.	Estimated Deaths from Plague.	Percentage of Mortality to Population.
84,948	4,638	5·46

Total Military Population.	Deaths from Plague.	Percentage of Mortality to Population.
15,133	141	0·93

Exact figures are, however, obtainable with regard to the fighting men of the native regiments. Their strength during the epidemic of plague was (*vide* Statement II. of the papers submitted) 2,900 inoculated men, in addition to eight uninoculated men who were attacked by plague, or 2,908 in all. Of these 25 died from plague, or 0·86 per centum.

In estimating the probable number of deaths among the total population, a fairly high death rate from causes other than plague has been assumed, and no account has been taken of the considerable exodus which took place among the civil population, which, if it could be accurately estimated, would show the percentage to be even more favourable to the military population.

The Principal Medical Officer thinks — in the Resident's opinion, with justice — that, considering the fact that the native troops were living in the close neighbourhood of localities which suffered severely from plague, the extremely small mortality from plague among them is a strong testimony of the efficacy of the inoculations that were carried out among them at an early stage of the epidemic.

I have not entered the figures of the uninoculated in the statements, because it is impossible to arrive at them accurately. All the people in the lines were supposed to be inoculated, with the exception of old women and people in a delicate state of health, but it is obvious that a great number must have remained uninoculated, especially among the followers of the British troops. I think so, because a certain number of cases have occurred which have been recorded as being among uninoculated persons, when everyone was supposed to be inoculated. The figures regarding the strength of the fighting men of the native troops may be taken as absolutely accurate.

25,139. Can you give me an example of that?—One example is in J. Battery, R.H.A. In the week ending the 9th December there was one case among the uninoculated, although the whole strength of the battery was supposed to have been inoculated on the 4th November. Similarly, in the 21st Field Battery, there were three cases occurring among the uninoculated in the weeks ending the 18th and 25th November and the 9th December, while the whole strength of the battery was supposed to have been inoculated on the 11th November. Similarly, in the 25th Field Battery, there were six cases among the uninoculated, although the whole strength of the battery was supposed to have been inoculated.

25,140. You conclude from this that there were more non-inoculated people than was known?—I think so; they did not succeed in inoculating the whole number, except among the native fighting men, and possibly among the followers of the native regiments.

25,141. In all these cases in which you put deaths as having occurred among the inoculated people, I suppose the fact that these people had been inoculated was verified?—Yes; it was entered in the medical officer's book, with the date. I should like to put in a chart,* showing the number of cases among the inoculated and uninoculated, and the number of inoculated persons week by week. I wish to state, as an indication of the efficiency of the inoculation, that the total mortality from plague among the fighting men of the native troops was only 0·86 per cent., whereas among the civil population it was estimated at 5·46 per cent.

* *See* App. No. LXXII. in this Volume.

(Witness withdrew.)

Mr. E. L. Cappel, I.C.S., recalled and further examined.

Mr. E. L. Cappel, I.C.S.

25,142. (*Dr. Ruffer.*) You have handed in a statement concerning Hubli, giving the inoculated population, &c.?—Yes.

25,143. Comparing these figures with the figures* handed in by Captain Leumann we found the two did not agree. Can you give us some explanation of that fact?—The explanation of that is that Dr. Leumann, as he has stated in his evidence, found it necessary from time to time to correct the figures which were given to him by the Chief Superintendent and by the other officers concerned.

25,144. In what way did he correct them?—By further inquiry, and on several occasions the figures were rather materially corrected in that manner. Dr. Leumann has said that those corrections were communicated to me as Collector, but I have searched the files, and I do not find that such communications were made to me at all—at any rate, there is no record on the Collector's files at Dharwar. I only used the original figures, and he has put forward the corrected ones, and, therefore, those corrected figures will stand. There was another point brought forward in Dr. Leumann's evidence, which was that his figures and mine did not agree as to dates.

25,145. There is only a difference of three days, and probably that was the time that they took to reach you?—The reason was that Dr. Leumann's figures, and the figures of all the other officers concerned in plague duty, were required by me for the special purpose of a weekly report to Government, which had to leave my office, or at least to be made up, on Fridays. In order to get those figures in time, the officers reporting to me had to report on Tuesdays and that makes the three days difference.

* *See* App. No. XV. in Vol. I. and Question No. 3064.

Mr. E. L. Cappel, I.C.S.
14 Mar. 1899.

25,146. If you take your figures you will see you give an account of the plague as far as the week ending the 2nd of December, whereas Dr. Leumann only gives them to the 22nd of October. Must you not correct the other figures now, because we can only take Dr. Leumann's figures as far as the last date in his report?—There are no corrected figures. The figures that are given beyond that may be taken to be accurate. They are not corrected by anybody, and there is nothing to show that they require to be corrected.

25,147. But did not all the other figures require to be corrected up to the 22nd of October?—No, all the figures up to August were not challenged at all.

25,148. But from August?—From August Dr. Leumann made corrections occasionally.

25,149. I think he made corrections in all of them; is that not so?—Yes, but those corrections did not amount to anything very vital. There is a difference of about 3,000 in inoculated cases, which, considering that the total inoculations ran up to 40,000, will not vitiate any inferences to be drawn.

25,150. Then you have no further corrections to offer?—I have no further corrections to put forward.

25,151. Then we take Captain Leumann's figures, as far as they go, as being your own figures?—Yes. I put in a statement reconciling my figures with his, as follows:—

HUBLI.

Weeks ending.	Population for the Week.	Inoculated			Uninoculated.	Attacks in					Deaths in

	Percentage of Deaths (Plague) to Population.*					
— Dharwar	—	—	3·2	·07	9·01	4·4
— Hubli	—	—	·3	· 6	6·04	7·

* Taken on average population, which is, for Dharwar, 21,808, and for Hubli, 42,040.

† These figures are not worth much. They arise from an unduly low proportion to the total inoculations and should not be generalised from. Also, there is the fact that many inoculations were done on persons already incubating plague. (*See* Dr. Leumann's Report, App. XV. in Volume I.)

	Attacks in		Deaths in	
	Dharwar.	Hubli.	Dharwar.	Hubli.
Once inoculated	115	491	42	129
Twice inoculated	29		7	278
Uninoculated	1,172	2,897	916	2,539
General	1,316	3,388	965	2,946

25,152. I believe you have a statement to make with regard to the enormous number of deaths among the uninoculated during the last period?—Yes, this statement which was embodied in my evidence, showed that in the third week of September there were only 143 uninoculated persons, and that there were 99 attacks among those, giving a percentage of between 60 and 70 per cent. for one week. Those figures had been reported by me to Government in my weekly report, but I pointed out in those weekly reports, what is a sufficiently obvious thing, that percentages drawn on very small figures are unsafe, and that was eminently so in this case, because those figures turned out not to be right. By Dr. Leumann's corrected record, the figures for that week should be:—Uninoculated persons 937, inoculated 38,205, and plague deaths among the non-inoculated 106, and among the inoculated 55. The percentage works out for the uninoculated to 113 per 1,000 per week, which is very different to the percentage formerly given.

25,153. That is exceptionally high?—Yes.

25,154. How do you account for this very high mortality among the uninoculated?—I do not account for it at all. In my evidence formerly given I stated that the virulence of the disease was very great at that particular time, and in that particular part of the country, and that the villages adjoining Dharwar and Hubli, which were similarly situated, and, if anything, in a better sanitary position, and where no inoculation was done, suffered to the extent of from 30 to 50 per cent. in the course of from six to 12 weeks, whereas the Hubli epidemic lasted 22 weeks.

25,155. One hundred and thirteen per mille would kill everyone in the town in less than eight weeks?—But 50 per cent. in six weeks will clear it out in 12.

25,156. Have you any other villages or towns of the same size as Hubli, showing a mortality from plague equal to that?—No. I would like to point out that, taking Dr. Leumann's figures, they are very small to draw percentages upon, and the deduction is not a very safe one.

25,157. We had it in evidence before us from several people, that the uninoculated population in Hubli was greater than that given in Dr. Leumann's Report. It has been estimated by several witnesses as being about 5,000?—I very much question that. No officer concerned with those operations could say, with certainty, that a census of that kind is absolutely accurate. There must be a margin of error, seeing the conditions in which those things are taken in India. But to assert that the census was out to that extent appears to me to be a statement very wide of the mark. The plague census was taken in exactly the same way as the Imperial Census was taken.

Mr. E. L. Cappel, I.C.S.

14 Mar. 1899.

25,158. When was the first census taken?—In October or thereabouts.

25,159. When did plague break out?—About that time. It was taken in exactly the same way as the Imperial Census was taken, that is to say, the houses were numbered, the town was divided into sub-divisions and wards, and a separate census paper was made out for each house. These papers were bound up in volumes, and constituted the record of each Supervisor and Superintendent, who went about with them daily in their hands. That was the first document on which the Supervisors and Superintendents worked. It was by these census records of each house that they tested whether people had arrived or had left, or were sick or had died. After the census was first made at the end of 1897, it was tested weekly during the operations by a corrected record being sent in for the purposes of that week's plague report.

25,160. Then you cannot account for that statement as given to us?—I think that statement errs very much on the side of exaggerating the error.

25,161. Is there anything else you would like to add?—I may say with regard to the discrepancy between Dr. Leumann's figures and my own, that the figures of incidence were never changed at all. They were his own figures, and there is no change to be made in them.

25,162. Do you put in maps showing the incidence of disease in Dharwar and Hubli?—Yes.*

25,163. (*The President*) Having regard to the Dharwar district generally, am I right in supposing that there has been a very remarkable amount of inoculation done in that district?—Yes, we have, up to date, inoculated nearly 100,000 people in the Dharwar district, nearly all of whom have been inoculated twice.

25,164. At what stage in the prevalence of plague was the inoculation commenced? Early or late?—Quite early in every case.

25,165. Am I right also in believing that there has been a very large amount of plague in your district?—Yes.

* *See* Appendices No. LXXIII. and LXXIV. in this Volume.

(Witness withdrew.)

SARDAR KHAN BAHADUR MUHAMMAD YAKUB KHAN called and examined.

Sardar Khan Bahadur Muhammad Yakub Khan.

25,166. (*The President.*) You are now on special plague duty in Bombay?—Yes.

25,167. When were you placed on this special duty?—On the 7th October last, in Bombay.

25,168. Previously to that you had been working in Karachi, I think?—Yes, on plague duty, but not immediately before that. Immediately before that I was Acting Deputy Commissioner in the Thar and Parkar district.

25,169. Were you on duty during both epidemics in Karachi?—Yes—the first being in 1897 and the second in 1898.

25,170. Will you describe the system which you found best suited for conducting plague operations?—Yes. My district there consisted of several villages of Musalmans. In each village I formed a committee of the leading members of the village, and conducted my operations through them, and with their co-operation.

25,171. What did these operations consist of?—Before I went there, there was opposition even to disinfection of houses, and to the segregation of contacts. In those days the sick were not removed to hospitals. After securing the co-operation of the Headmen, we arranged for segregation camps, and removed the contacts from the infected houses to the segregation camps and the sick to the sick camps. That was always done by the Headmen themselves.

25,172. What special advantages do you claim for your system?—The people were ignorant and excitable; through the Headmen they understood things better, and things went on more smoothly, and, I think, more quickly.

25,173. You got earlier information of plague cases, and were able more easily to remove the sick and the contacts?—Yes.

25,174. Was any evacuation of a large area attempted?—Yes, on a large scale. In the first year, three whole villages were moved into health camps one after another. That was arranged through the Headmen.

25,175. What was the population of each village?—In the first village it was 1,600. Half went away to the hills and the other half came into camp. The second village had 913 people.

25,176. They all went out?—Yes.

25,177. And the third village?—I have not the figures at hand now for the third village.

25,178. Was it smaller than either of the other two, or larger?—It was smaller than either of them.

25,179. Had plague already taken a strong hold in these villages before evacuation?—Yes.

25,180. In general terms, what was the result of the evacuation so far as the spread of plague was concerned?—With regard to the first village, we had no plague case in the camp after the first ten days. I say, from recollection, that there were only 18 cases in the first ten days.

25,181. How many cases had there been before evacuation in the first village?—There were about five cases a day before evacuation.

Sardar Khan Bahadur Muhammad Yakub Khan.
14 Mar. 1899.

25,182. How many days had that been proceeding?—Not less than ten days.

25,183. Now, with regard to the second village?—In the second village there were three plague cases only after evacuation. Before evacuation, we had two or three cases every day.

25,184. For how many days?—I should say for one week.

25,185. Now, with regard to the third village?—I have not the figures for that.

25,186. What is your opinion as to the value of evacuation in stopping an extending epidemic?—I am strongly of opinion that it stops it.

25,187. Did you have any experience in Karachi city?—My quarter formed part of the city. The people from Karachi city in the second epidemic camped outside in what is called the Trans-Lyari area. Half of that area was given to my charge. In all 30 voluntary camps were made by the people in my portion, and the population of that was 14,000. The other portion was given to another officer, and there were 11,000 people there.

25,188. Making a total of 25,000 all out at the same time?—Yes.

25,189. Had that a beneficial effect upon the spread of plague in Karachi?—Decidedly it had, I was watching each camp, and after ten days I did not find plague cases there. If there was any rare case found, I traced it to some infected people coming in without permission.

25,190. How long were the people kept out of their houses?—It varied slightly; on an average six weeks to eight weeks.

25,191. What was done with the evacuated houses before the re-admission of the people?—I was not concerned in that; it was done in the City Proper, but I know that there was an arrangement for general disinfection of all houses in the city. It was very thoroughly done.

25,192. Was it by chemical disinfectants?—Yes, under the supervision of medical officers specially appointed.

25,193. Were the houses opened up and unroofed?—Where it was necessary; not always.

25,194. What is your opinion of the duration of a plague epidemic if it be not interfered with?—I have not had experience of that.

25,195. If it be interfered with, what do you think is the general duration?—Four months.

25,196. That will depend upon how it is interfered with; you have already said it appeared to stop in ten days?—Yes, ten days for the people, but for the infected locality, I should say, two months. I would not see it re-occupied before two months.

25,197. Have you had any experience of plague affecting a second time a house in which it had occurred before?—Yes, my impression is that a large proportion of plague cases occur in those houses in which plague cases have previously occurred.

25,198. Is that after they have been vacated for several weeks, and disinfected?—No, I cannot say in those which had been vacated for several weeks, but in those which had been vacated for the ordinary period, namely, 10 days, and disinfected in the best manner laid down for us, cases did occur in the second epidemic.

25,199. Have you had any experience of inoculation?—Not much, except in respect of a portion of the population of two villages. In one village about 300 persons were inoculated, and I turned out about 200 from that village into a health camp when I found the village was getting infected.

25,200. The 300 people who remained were inoculated, and the 200 who were evacuated were not inoculated?—That is so. The 300 chose to get inoculated because they did not wish to leave the village. There were two cases of plague after inoculation, not before a fortnight I think.

25,201. Had there been many cases before evacuation?—Two per day.

25,202. Have you any other instance?—In another village 200 Memons were inoculated, they also got themselves inoculated because they did not wish to be turned out of their village. In that village there was about one case per day before the inoculations. After the people were inoculated there was no plague case in that village.

25,203. How many people were there in this village altogether?—These 200, and 100 more.

25,204. What became of the other 100?—I sent them to a health camp.

25,205. Before the inoculations?—Yes.

25,206. It is a similar case to the former one?—Yes.

25,207. In the case of plague becoming indigenous in a town of, say, 5,000 or 6,000 people, what would be your advice?—My advice would be to evacuate the town, if that were possible.

(Witness withdrew.)

Khan Bahadur B. B. Patel.

KHAN BAHADUR BOMANJI BYRAMJI PATEL called and examined.

25,208. (*The President.*) I believe you are a Justice of the Peace?—Yes.

25,209. What has been your relationship to the plague epidemic?—For the last two years I have been a volunteer in searching for plague cases.

25,210. (*Mr. Cumine.*) Are you a volunteer witness also?—Yes.

25,211. In what part of the city did your work lie?—In the Fort district.

25,212. From what period did it extend?—It commenced from March 1897.

25,213. Up to when?—Up to now.

25,214. To what class of the community are your observations chiefly confined?—Chiefly to the Parsees.

25,215. To how many of them?—Nearly 8,000. There are 360 houses in the block which is entrusted to me.

25,216. What proportion would that form of the total population in Bombay?—About one-sixth of the Bombay Parsee population.

25,217. How many plague cases among the Parsees have come under your immediate observation?—Nearly 125.

25,218. Have you noticed whether deaths among rats have generally preceded, or followed, attacks amongst human beings?—Preceded.

25,219. Is it, in your opinion, dangerous to continue living in a house where dead rats have been found?—Yes. I have explained the matter to several people, and told them not to live in houses where dead rats were found, but, notwithstanding, they live there. Within the last week I have seen plague cases where dead rats have been found.

25,220. Have you found that in a certain class of houses the death of rats is not necessarily followed by plague amongst human beings, and if so, in what class?—In some large and well-ventilated houses I have seen dead rats on the ground floor and on the upper storeys, and no plague cases have occurred, even on the ground floor.

25,221. Do you think segregation has had a good effect in Bombay?—It has had a very good effect among the Parsees.

25,222. How has that effect shown itself?—This year's mortality among the Parsees is about three-fourths less than the previous year.

25,223. Is there more segregation this year than there was before?—Yes. Nearly 2,500 people from the Fort have been segregated.

25,224. What do you call segregation?—The people live in the camp.

25,225. That is evacuation?—Yes. They have lived in camp on the Esplanade, on the Chowpati, and in six more other localities.

25,226. Voluntarily?—We persuaded some people to go out. Of course all did not go voluntarily. In several cases where dead rats were found, we persuaded them to go out.

25,227. Have you noticed whether plague cases this year occur sometimes in the same houses, or whether they occur in different houses?—Cases have occurred in the same houses, and I have seen cases occur even in the same rooms.

25,228. I suppose cases have also occurred to a large extent in the other houses and other rooms?—Yes, in other houses also.

25,229. Do you consider from what you have seen that plague is contagious?—No. Yet being a layman I cannot form an exact opinion, though I have seen people embracing, hugging, and kissing patients. Last week I saw in one family people embracing a patient.

25,230. What has the result been?—They have not been attacked.

25,231. Last week is rather recent?—I saw similar instances in January; but last week there was a plague case in my block, and I saw the people embracing the patient.

25,232. Have you had any considerable experience of Professor Haffkine's inoculations?—Yes.

25,233. How many people have been inoculated?—Amongst the Parsees 6,478 people have been inoculated since the year 1898, and there has been no death amongst them within the last six months from the date of their inoculations.

25,234. If there had been any deaths would you have heard of them?—Yes. We keep a register of deaths in our Towers of Silence. The register states whether the people are inoculated or not. It also gives the cause of death.

25,235. Has anybody examined that register to see to what extent inoculated people have died of plague?—All the particulars are in the register; whether they have died from plague or not, and whether they are inoculated or not.

25,236. Have you examined the registers often?—Yes.

25,237. You say over 6,000 people have been inoculated. That would be about one-eighth of the population. Then, even though the inoculated people died at the same rate as the uninoculated, you would expect to find in your register seven who died uninoculated to one who died inoculated, would you not?—Yes. Several people have died from plague one year, or nine months or eight months, after inoculation, but not within six months.

25,238. Have you worked out the figures from the registers?—No; from newspapers. I saw it in the Government Gazette. *Khan Bahadur B. B. Patel.* 14 Mar. 1899.

25,239. Has any case come under your notice where an inoculated Parsee has caught plague and died?—Yes; but the death has occurred after six months from the date of inoculation.

25,240. How many?—I cannot give the definite number, but I have seen some two or three inoculated cases having recovered.

25,241. (*Dr. Ruffer.*) How many inoculated people have died from causes other than plague?—A great many. Some have died of consumption, and some from fever and dysentery.

25,242. Can you tell us how many have died from causes other than plague?—No; I cannot tell you the exact number.

25,243. (*The President.*) Has your experience been chiefly amongst the Parsees?—Yes, amongst the Parsees only.

25,244. Do they dwell in rather better houses than the majority of the people?—Most of them dwell in better houses than the majority of the people. The 125 cases were mostly on the ground floors; and not on the upper floors.

25,245. When segregation was adopted this year, was it ever applied to people living in houses where there had been no plague cases, but which adjoined plague houses?—To people in houses in which plague cases occurred, or in which dead rats were found.

25,246. Not to adjoining houses?—No. We give people permission to go and live in the huts when dead rats are found, or when plague cases occur in their houses or in the neighbouring houses. When there are no plague cases, and when no dead rats are found, we do not give permission to the people to go and live in the huts.

25,247. So that the evacuation has been restricted to houses in which plague cases have occurred or dead rats have appeared?—Yes, so far as the Parsees are concerned.

(Witness withdrew.)

Dr. U. L. Desai called and examined. *Dr. U. L. Desai.*

25,248. (*The President.*) What are your qualifications?—M.B. and B.C.H., Victoria University, Owen's College, Manchester; L.R.C.P., L.R.C.S., Edinburgh; L.M., Edinburgh; L.F.P. and S.G., M.D., Belge, M.C.P., A.C.P., London; Consulting Physician Moah and Porwad Plague Hospital.

25,249. What is your opinion as to the cause of plague?—It is a manifestation of septicæmia by a specific virus in a filth diathesis.

25,250. In regard to the propagation of plague, what, in your opinion, are the chief causes of that propagation?—The chief cause is the infection by bacillus.

25,251. How is it spread or propagated?—By direct contact, by contagion, by inoculation from the earth, by aerial infection, by aqueous infection, by clothes and other fomites.

25,252. Have any of the lower animals got anything to do with it?—Yes.

25,253. What animals?—Rats, and other rodents.

25,254. Have you got any examples in which rats appear to have actually produced the disease in human beings?—I have seen one or two cases in which dead rats have been found in the houses, and the people living in the houses have vacated them at once, and then plague has broken out in the next house.

25,255. In the house without the rats?—Where the rats have not died.

25,256. How do you associate that contagion with rats if rats were not in the house in which plague occurred?—Before the rats came to that particular house where they died they must have been moving about; they do not stay in one particular locality.

25,257. These people might also have come in contact with plague contagion in other ways, might they not?—Yes, they might.

25,258. Have you anything to show that rats did it, anything more clear and definite?—No, except that I have observed plague invariably breaking out in houses not vacated after rats dying in them.

25,259. What is your opinion as to the origin; is it an introduction, or does it arise spontaneously?—From analogy, from cholera and other specific diseases, I think the disease can arise *de novo*.

25,260. The only reason for saying that is analogy?—Yes.

25,261. No fact in relation to plague itself?—No. It being a specific disease, it could not differ in its methods of origin and propagation from other diseases of the same class.

25,262. What are the most important predisposing causes of plague in your view?—Overcrowding, lowering of the vitality of the people by habitual derangement of health, as over fatigue, anxiety, habitual disregard of hygienic rules, diet, exercise, clothing, air, and water.

25,263. Everything insanitary?—Yes, both from a personal and a general point of view.

25,264. Amongst which things you place overcrowding first?—Yes. Overcrowding, and the pollutions of earth, air, and water resulting from it.

25,265. What about the exciting causes, or immediate causes?—Infection by a specific bacillus.

25,266. Has it come within your observation that any special classes of the community are more liable to plague than other classes?—The poorest, who live in damp filthy localities, are the most subject to this class of disease.

25,267. That is a new condition. You did not mention that before. That you distinguish from overcrowding?—Yes. They might act together or separately, overcrowding, filth, and dampness. Before plague broke out in Bombay, Poona, and Surat exceptionally heavy rains had fallen, increasing dampness and atmospheric humidity, besides the rise of subsoil water level.

Dr. U. L. Desai.

14 Mar. 1899.

25,268. You think dampness in an open house might be a strongly acting cause?—Indirectly, because dampness will give a fit condition for the bacilli to grow in. A certain amount of moisture and heat are necessary for the growth of bacilli. Dampness supplies moisture.

25,269. Overcrowding you still keep in the first place?—Yes.

25,270. What communities are least liable to plague?—Europeans.

25,271. How do you explain their relative immunity?—By being removed from overcrowding and the causes of infection, in the first place; and in the second, by having more vitality in them.

25,272. What do you mean by vitality?—Capacity to resist the inroad of a disease. They are a better-lived class of people. Their nourishment is of a superior order to that of other communities that contract plague.

25,273. Is not that covered by what you mean by vitality?—Yes. Good nourishment means more vitality.

25,274. Are there any other causes?—The sanitary surroundings in which they live.

25,275. And that other great factor which you have referred to, overcrowding, has that anything to do with it?—Yes; it is much less amongst Europeans.

25,276. What do you think should be the plan of campaign against plague?—Battle against plague has to be waged not only as against a specific disease, but as against general causes of unhealthiness leading to lowered vitality of the masses, and consequent increased mortality. It will have to be a huge war against the continued forces of hereditary habits, religious prejudices, conserved customs, and extreme ignorance of the laws of personal, social, and public hygiene, which go to make up the social life of an Asiatic. It is to be a thorough meeting of the sanitary and medical needs of the country, by numerous compulsory enactments and institutions, which shall be bitter pills for the masses of India to swallow, and unless that is done, plague germs shall find fit nidus to grow, multiply, and cause ravages in various parts of India.

25,277. Therefore you think that a large improvement in the first place in the sanitary condition of the people is the fundamental reform required for diminishing plague epidemics; is that your view?—Yes.

25,278. What are the chief remedies you would propose against plague?—The chief remedies against plague are:—

Temporary.—Isolation of those attacked from the healthy, and removal of the inhabitants of the affected area to healthier localities.

Permanent.—For Bombay:—

1. To improve its drainage and sewerage. The most of the drains of Bombay are below sea level, some of it even below spring-tide low water mark, and nearly the whole of it too slightly elevated to admit of gravitation into the sea, at a distant point of outfall, and hence, improvement in the gradient is necessary.
2. An Act for the better housing of the people in Bombay, with a view to lessen the overcrowding in badly-constructed, ill-ventilated and ill-accommodated houses, and increase the responsibility of the proprietors of houses, that are let to lodgers.
3. Inspection of houses, as regards cooking, washing, sleeping, and other accommodations, and as regards walking barefooted on a filthy soil.
4. Necessity of a Rent Act, to control exorbitant rents by greedy proprietors.
5. Compulsory notification of infectious diseases, and to obtain this end, introduction of an Act for medical practitioners, qualified or unqualified, specifying the responsibility of such practitioners.

For Bombay and other Parts of India.

6. Food and Drugs Act.
7. A scheme to promote the knowledge of personal and General Hygiene among the inhabitants of India, as by instituting Degrees in Sanitary Science at Bombay, Calcutta, Madras, and Punjab Universities. To set a paper on this subject at the Matriculation and School Final Examinations, and make Sanitary Science a compulsory subject at the Indian Civil Service Examination.
8. To organise a Competitive Sanitary Civil Service for India.
9. A scheme for village sanitation and healthy water supply for human beings and cattle.
10. A scheme to supply better midwives for natives.
11. A scheme to direct the charitable instincts of the wealthy Indians to organise a system of medical relief in the homes of the poor.
12. An institution to supply nurses for infants and invalids among the Hindus and Muhammadans.
13. A scheme to encourage cremation of dead bodies of men and animals.
14. To enforce burning of all excretions and secretions of human beings and animals suffering from Infectious Diseases, particularly in Hospitals.

25,279. What do you mean by "Specifying the responsibility of such practitioners" as bearing upon the treatment of plague?—The first point is that, unless a man knows differential diagnosis, he cannot properly diagnose whether a case is plague or any other disease. It has actually come under my notice that a case of gonorrhœal bubo has been diagnosed as plague, and sent to a Plague Hospital in my charge.

25,280. You do not exclude unqualified practitioners?—I want to exclude them; but at present they are practising in India, and consequently I cannot exclude them. If an Act for Medical Registration is passed in India, the best thing would be to have an Act for qualified medical practitioners.

25,281. To register the qualifications of those who possess them?—Yes, and to give permission to qualified and registered practitioners only to practise, the same as it is in England.

25,282. Do you think the country is yet ripe for such a large measure?—Yes, I think it is quite ripe for the occasion, particularly the large towns of India, as Bombay, Madras, and Calcutta, where Medical Graduates of European and Indian Universities abound. In a city like Bombay the Act would work very well, now that the plague is on, for it will help the authorities to get at the real extent and home of plague which lies hidden under lies, quackery, and superstition.

25,283. I do not refer to the practitioners themselves, but in so far as the lower population is concerned. Do you think they are prepared for a measure of that kind?—When suttee and infanticide were practised, the measures taken for their suppression had to be strong measures. The will of the people is not to be taken into consideration, but their welfare is to be taken into consideration, and I think the British Government will confer the greatest boon upon India if they tried how this Act for qualified practitioners would work—at least in the city of Bombay. Numerous untold blessings to the ignorant masses will spring from this source.

25,284. What proportion, do you think, of the people do not employ qualified practitioners?—About three-fourths.

25,285. What proportion, do you think, do not employ any practitioners whatever?—At present the people refrain from taking any advice at all. They are afraid, if a case of fever is attended by a medical man, that he will report it as a plague case, and that the person may be removed to the isolation hospital.

25,286. I do not refer to the present period, but prior to this scare about plague. What proportion had no medical advice—no doctor?—Almost one-fourth.

25,287. And three-fourths do not have qualified practitioners?—No. This three-fourths include those that do not take any medical advice.

25,288. But still you think that a measure which prevented other than qualified practitioners from practising could be enforced—could be brought into operation?—Yes; provided vaids and hakims of a certain intellectual and moral standing already practising be given special licenses as qualified vaids and hakims, and an examining board for future vaids and hakims be instituted under Government supervision.

25,289. You think it would be very desirable?—It would be very desirable.

Dr. U. L. Desai.
14 Mar. 1899.

25,290. (*Mr. Hewett.*) Do you know anything of any places outside the Presidency towns?—Yes. I have been in Surat and seen plague there.

25,291. Do you know anything about the feelings of Muhammadans in Northern India as regards the employment of vaids and hakims?—Yes.

25,292. What are their feelings?—The feeling is that they prefer vaids and hakims, but in places like the Punjab there are universities for vaids and hakims. The Punjab University has a scheme whereby it gives its qualifications to vaids and hakims after a certain source of study.

25,293. In European medicine?—No, in country medicine; but it is modified upon a European basis.

25,294. When you propose the registration of medical men, do you propose to register those who practise by the European system, or those who practise by native methods?—If a special examination is held for native medicines on the same lines as that of the Punjab University, they may be included as qualified practitioners, I would propose to register two classes of qualified practitioners, one practising the European system, enjoying greater freedom in the scope of the medical, surgical, and midwifery work to be performed by them, and with power to sign a certificate of death. The other a class of qualified vaids and hakims, whose sphere of work will be curtailed, so far as surgery, midwifery, and signing of death certificates were concerned. They might also be prevented from using certain poisonous drugs, as arsenic, aconite, mercury, morphia, &c. As the masses will realise the superior privileges enjoyed by the class practising the European system, the class of vaids and hakims will gradually diminish. I do not want to deprive the Hindus and Muhammadans of their vaids and hakims, as it partly is a religious question, but I wish to give them better vaids and hakims with some qualifications and a sense of responsibility, while practising a profession on which the life and death of a human being depends. I may mention that the question is apparently a complicated one, and is believed by many to be impossible of realisation, but I know for certain that the details are easy of arrangement; only that in the starting of this Act, vaids and hakims of a certain intellectual and moral standing already practising will have to be given licenses as qualified vaids and hakims without any examination, and a Board appointed under Government supervision to examine and grant qualifications as vaids and hakims in future.

25,295. Do you agree with the opinion expressed by many European medical men who have appeared before this Commission that the people do not like to be treated for plague according to European methods?—I do not agree with that opinion. I have been practising here for the last three years, and I know that they appreciate and prefer European medical attendance if they can afford it. The only bar is the heavy fees charged by European medical men. A love for skilful European medical and surgical practice is increasing even among the ignorant masses.

25,296. Are they in the habit of charging fees for attending plague cases?—Not now, because the plague cases are mostly attended in the hospital.

(Witness withdrew.)

(Adjourned till to-morrow.)

At The Secretariat, Bombay.

SIXTY-SIXTH DAY.

Wednesday, 15th March 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT.
Mr. A. CUMINE.
Dr. M. A. RUFFER.

Mr. C. J. HALLIFAX (*Secretary*).

Mr. C. H. Cayley, M.B.
15 Mar. 1899.

Mr. C. H. CAYLEY, M.B., called and examined.

25,297. (*The President.*) You are Master of Arts and Bachelor of Medicine?—Yes.

25,298. Have you an appointment here in connection with plague?—Not now.

25,299. You have had?—I was working in the laboratory with M. Haffkine.

25,300. As an assistant?—Yes.

25,301. (*Dr. Ruffer.*) You have made some observations on the presence of plague bacilli in the sputum?—Yes.

25,302. In cases of primary and secondary plague pneumonia?—Yes.

25,303. How did you examine the sputum in order to find the bacilli?—I dipped a glass rod in the sputum and inoculated a series of agar tubes with this glass rod, and immediately after inoculating the tubes, I covered them up from the light.

25,304. Do you find that an essential precaution?—I never found bacilli growing unless I did do that. Then the agar tubes were allowed to incubate for 24 or 48 hours, and from the colonies that developed fresh agar tubes, and also flasks of peptone broth, were inoculated.

25,305. Do you find the bacillus is often present in cases of primary plague pneumonia?—In all the cases I examined it was forming nearly pure cultures at first.

25,306. What is the sputum of plague pneumonia like at first?—A bright brick-pink and very glutinous, coughed up with difficulty. After a few days it gets looser and a darker colour, and as the case goes on it gradually becomes muco-purulent.

25,307. Do you find the number of bacilli increases or diminishes in the sputum?—It diminishes.

25,308. When does it begin to diminish?—In primary plague pneumonia, after the third or fourth day, they were distinctly less.

25,309. Most of the cases of plague pneumonia die?—Yes.

25,310. But you saw two cases which recovered?—Yes.

25,311. Did you make any examinations as to how long after the fever had subsided the plague bacilli could be found in the sputum?—Yes; I did not see either of these cases till after the fever had subsided.

Mr. C. H. Cayley, M.B.

15 Mar. 1899.

In one case it was 10 days after the fever had subsided that there was plague bacilli in the throat. There was no cough or expectoration.

25,312. Were you able to isolate the plague bacillus?—Yes.

25,313. And reproduce the disease in animals?—A rat was inoculated, and it died in 4½ days.

25,314. A rat inoculated with the sputum itself?—No, with ½ c.c. of an agar culture.

25,315. How do you know these cases were primary plague pneumonia if you did not see them?—I saw the doctor in charge, and got the history of the cases. They had been entered as plague pneumonia, and, in both cases, there had been consolidation of the lungs and no buboes.

25,316. What are the physical signs of primary plague pneumonia?—At first there are no signs pointing to the lungs at all. In the earliest cases I saw, there seemed to be no sign pointing to any particular organ at all. Then a cough developed, there was expectoration, and then I detected some consolidation of one of the bases.

25,317. Is the whole base affected?—No, only a portion.

25,318. It is a patchy sort of pneumonia?—Yes; in all the cases there seemed to be some distinct part where it started.

25,319. Does it affect both lungs or only one lung, as a rule?—In one of the cases both lungs were affected, but in most of the others it was one, and then there was general bronchitis.

25,320. The discharge from the mouth is sometimes extremely profuse, is it not?—Yes.

25,321. When do the secondary lung symptoms generally show themselves?—About the fifth or sixth day.

25,322. Is that the rule in every epidemic?—I do not think so. In Poona there were hardly any lung symptoms.

25,323. Have you made any observations in the present epidemic?—No, I have not.

25,324. You are referring to the epidemic of last year?—Yes; March, April, and May of last year.

25,325. The symptoms came on on the fourth or fifth day?—Yes; sometimes as late as the eighth day.

25,326. What physical signs did you find in the lungs?—Signs of acute bronchitis and patches of consolidation.

25,327. Did you ever find consolidation of the lung?—No; only a few patches where there was a little bronchial breathing, perhaps—no definite consolidation.

25,328. Did you ever notice signs of œdema of the lung?—In the later stages, when the patients were exhausted, at the back.

25,329. Did you notice signs of pleurisy?—No.

25,330. Is the sputum profuse in such cases?—Yes; it is fairly profuse, but not excessive.

25,331. Is not there a great deal of difficulty in bringing up the sputum?—Yes, there is.

25,332. The patients strain a good deal?—Yes.

25,333. Did you find the plague bacilli in such cases in the sputum?—In a fair number of cases.

25,334. In how many?—In 17.

25,335. Out of how many?—There were 43 after I had got the technique, and had worked out the best method for isolating the bacillus.

25,336. By cultures?—Yes.

25,337. In how many cases did you find it microscopically?—I found everyone of them had it, practically.

25,338. Did you find there were other bacteria present as well?—Yes.

25,339. What bacteria did you find?—A diplo-coccus was common at the start.

24,340. Did you find Friëdlander's diplo-coccus?—I never went beyond the fact that there was a diplo-coccus.

25,341. Did you find strepto-cocci common?—Yes.

25,342. For how many days did you find plague bacilli in these cases?—As a rule, about a fortnight after the lung symptoms developed; but there was one case which was 28 days, three days after the temperature was normal.

25,343. Did you isolate it in that case?—Yes.

25,344. Did you find that the plague bacilli in such cases were virulent?—I inoculated three rats; they took three or four days to die, and the primary pneumonia case died after 36 hours.

25,345. I think in one case you found the plague bacilli for five days only?—Yes.

25,346. In 13 cases the plague bacilli were found in periods varying from 10 to 14 days, in one case 15 days, in one case 19 days, and in another case 23 days?—Yes.

25,347. (*The President.*) You have tested clothes for the bacillus?—Yes.

25,348. Will you be good enough to tell us what was the result of your testing?—I never succeeded in finding the bacillus in any clothes which I examined.

25,349. These clothes had been worn by plague patients?—Yes.

25,350. In any cases had they been removed from a corpse?—Yes.

25,351. You examined portions of these articles of clothing and did not find any?—That is so.

35,352. You have examined the perspiration, I think?—Yes.

25,353. With what result?—I never found the plague bacillus in it.

25,354. You examined the saliva?—Yes.

25,355. With what result?—I found the bacillus in ordinary bubonic cases occasionally. I examined five cases where the parotid or submaxillary gland was affected, and I found it in each case. In one case I found it in the secretion 10 days after the temperature had become normal; the glands were still enlarged, but they had not suppurated.

25,356. Ten days after the apyrexia, you found it?—Yes.

25,357. Is that the longest period?—Yes; I never found it in any other case after the temperature was normal.

25,358. Have you examined the urine?—Yes: I failed to find it in the urine.

25,359. Have you made a large number of examinations?—About 15.

25,360. At what stages of the illness of the patients?—At all stages.

25,361. Will you describe the process you followed for separating the bacillus if it had been in the urine?—I collected the urine direct from the bladder with a catheter and passed it into a conical vessel and allowed the vessel to stand covered up from the air. After it had been covered up for three or four hours I took a small drop from the sediment at the bottom and inoculated broth with that. Drops of this inoculated broth were added to tubes of liquid agar, and plates and rolled tubes were prepared from them. Numerous colonies of bacilli developed, but I never succeeded in isolating the plague bacilli.

25,362. You did not centrifugalise?—No.

25,363. What has your experience been with regard to fæces?—I examined two or three cases of fæces. In one case where the motions consisted of nearly pure mucus I managed to isolate the bacillus, but that was the only case.

25,364. Out of how many?—About five altogether.

25,365. Was this the only case you examined in which the symptoms were specially abdominal?—Yes.

25,366. Have you examined the epidermis of the tongue?—Yes.

25,367. With what result?—I examined about 20 cases and I found it twice in the fur at the back of the tongue.

25,368. At what stage of the illness?—The patients had been ill for some time—about 10 days.

25,369. They were becoming convalescent?—Yes. They still had fever and were ill, but they were out of danger.

25,370. Have you anything to add to what you have said as to the examination of buboes?—No. I could

always get plague bacilli from the buboes before suppuration had taken place, but after suppuration I never succeeded in getting it—at least, not from the pus. I got it from the part of the bubo which had not broken down. There was one case of bubo which had not suppurated, and the patient was convalescent and going about. I tried it, but I did not succeed in getting any bacilli from it.

25,371. What is the latest period in the disease in which you found any bacilli in the bubo?—In all the cases in which I found it the temperature was still high.

25,372. Within 10 days?—Yes. I did not make any special attempt to find out how long.

25,373. But the maximum period is about 10 days?—Yes.

25,374. I think you made some examinations of earth in different localities?—Yes.

25,375. In what localities?—In Poona and Bombay.

25,376. Where in Poona?—From the floor of infected houses and the graveyards of Poona.

25,377. What were the results?—I never found it.

25,378. Taking infected houses, how many have you examined?—About 30 or 40.

25,379. Did you take a mixed sample of different parts of each floor or only one part?—It varied. Sometimes, if a patient had been lying on a particular place, I took a part from there. If I did not know anything about the matter I took samples from different parts, avoiding the fire-place and where the light shone in.

25,380. At any rate, you included, in your examination, earth which you knew had been very close to the patient?—Yes.

25,381. You examined also the earth of graveyards?—Yes.

25,382. With what results?—I never could find the plague bacillus.

25,383. The floors which you examined were cow-dung floors, were they not, in all the cases which you have referred to?—Yes.

25,384. Have you examined any dust in infected houses?—Yes.

25,385. Where did you collect it from?—I got it from all parts, from the ceiling and the walls, from niches in the walls, and from the sweepings from the floor.

25,386. What was the result?—The result was negative.

25,387. Were your examinations numerous?—Not with regard to the dust, particularly—that came in with the earth floors; I generally did some of the dust in the room when I did the earth floor.

25,388. That was a considerable number, apparently?—Yes; I suppose about 15 or 20 times I tried the dust.

25,389. Did you examine any of the hangings or the clothes in the room where patients had been living?—Yes.

25,390. What were they?—Mats in the room, hangings on the wall, and cotton or anything which I found lying about.

25,391. Did you examine any clothes?—Yes; soiled rags and anything I found left in the room.

25,392. Did you make a large number of examinations?—No; in about five or six houses.

25,393. What was the result of that?—In one case I found the bacillus on a piece of matting.

25,394. Had that been hanging up?—It was actually hanging up when I found it, but I was told it had been used for the bedding of the patient who had died, and it was certainly soaked with the discharge.

25,395. Fæcal or urinal?—Urinal and the saliva from the mouth.

25,396. Not fæces?—No.

25,397. I think you have made some examination of the temperature of plague in the steam apparatus and of the penetration of that temperature to bundles of clothing?—Yes. At Poona a steriliser was used at the railway station. The clothes of each passenger were tied up tightly into bundles and put in. To effect penetration to the centre of these bundles sufficiently to kill the plague bacillus, we had to get a pressure of 15 lbs. to the square inch and keep it at least for a quarter of an hour.

25,398. How large was the biggest bundle?—2 feet by 2 feet 6 inches generally, in long bags.

25,399. And you found that penetration extended to the centre?—Yes.

25,400. How did you ascertain that?—I got glass capsules with living plague growths in broth and placed them right in the centre of the bundles: and after the exposure to the steam, fresh broth and agar tubes were inoculated from the contents of these capsules.

25,401. You did not ascertain the actual temperature?—No; there was no registering thermometer.

25,402. (*Dr. Ruffer.*) What disinfector was it?—It was a locomotive boiler. The steam was introduced from a stationary engine.

25,403. How big was the bundle?—Just the clothes of the people who came up; they were all sizes. I suppose the biggest I tried was 2 feet 6 inches by 2 feet. They could not touch the bundles at all for 10 minutes or a quarter of an hour after their removal from the boiler. When they had only 10 lbs. pressure, the bundles could be handled directly they were brought out, the heat did not penetrate. 15 lbs. pressure for 10 minutes was not sufficient.

25,404. That corresponds to what temperature?—I had not a thermometer, but I suppose about 220° F. or 224° F.

25,405. Have you ever examined the blood of patients for plague bacilli?—Yes, microscopically.

25,406. Not cultures?—No.

25,407. Have you ever found it in a case of plague which recovered?—No, not in any case; but I saw some slides of blood which Dr. Marsh had taken.

25,408. And the patient recovered?—Yes. Apparently, they were plague bacilli.

25,409. (*The President.*) In these pneumonic cases which you have referred to, did you ever search for the pneumo-coccus either in the primary or secondary cases?—I did not search specially for it. I was only looking for the plague, but there was a diplo-coccus constantly present in the secondary pneumonia which was only occasionally present in the primary pneumonia.

25,410. You could not identify that with the pneumonia coccus?—I thought the secondary pneumonias were primary pneumo-coccic infections. That is the idea I got from the examination of the sputum.

(Witness withdrew.)

Mr. Sorabji Manekji Damaun-Valla called and examined.

25,411. (*The President,*) You are a volunteer witness, I think?—Yes. I was nominated by the Collector of Surat.

25,412. Will you state to the Commission what have been your opportunities of observing plague?—When the first epidemic broke out in Daman I was called there, and I saw the people dying of plague.

25,413. Have you had experience elsewhere?—No.

25,414. (*Mr. Cumins.*) When did your experience in Daman begin?—At the beginning of the first epidemic in March 1897.

24,415 Up to what point did your experience last?—To the end of the epidemic in July 1897. Then there was a recrudescence in March 1898 up to June, and the third epidemic is now going on.

25,416. Have you had experience of all three epidemics in Daman?—Yes; I was there all the time.

25,417. I think you have come to speak about inoculation chiefly?—Yes.

25,418. Have you done any inoculations yourself?—I have.

25,419. How many people did you inoculate yourself?—About 200.

25,420. Did you keep a watch upon these people to see what happened to them?—Yes.

Mr. S. M. Damaun-Valla.

15 Mar. 1899.

25,421. Upon the whole 200?—Upon all those who were inoculated through me.

25,422. How many would that be?—About 4,000, inoculated at my expense—of course from time to time. In the beginning of 1897 I sent for Dr. Kalapesi. He came thrice to Daman through the courtesy of Dr. Haffkine and inoculated about 2,000 people, and about 200 by Dr. Poiares, and then the Government sent for him, and I have nothing to do with that. Then, again, I sent for Dr. Dubash. He inoculated 1,115 persons, including inoculation by me, and then again this year he has inoculated 397. This includes my own inoculations also. Besides this about 200 persons of my village of Katheria were inoculated by Dr. Fernandes.

25,423. In what month were the 2,200 people inoculated?—In March, April, and May 1897.

25,424. In what month were the 1,115 and 200 inoculated?—In April 1898, within nine and four days respectively.

25,425. And the 397?—Last month—February.

25,426. What part of Daman did all these three sets of people live in?—In Daman Proper, where I live Katheria, which belongs to me, and Kariwari, a group, of three villages. I have brought a map here which will show the position and topography of Daman.*

25,427. To what extent were you able to keep a watch upon these three groups of inoculated people?—I had about half a dozen agents who know all the people. Whenever the people were inoculated I used to send them round every day to ascertain how they were getting on, especially in the first year.

25,428. To 2,200 people?—Yes. They are all known to me, and I have every facility to make inquiries. Then it is a small area, about 1¼ miles long and three-quarters of a mile broad. I, myself, used to visit them whenever I could, and I was all the more interested, as I had introduced inoculation and I did not know what effect it would produce.

25,429. What practical effect did it produce?—It had a wonderful protective effect. Those who were inoculated were protected from plague, and a very small ratio died—about two per cent.—whereas the uninoculated died in numbers—about 70 per cent. taking all the three seasons together.

25,430. How do you know how many of the inoculated died?—I had my servants, who were always going about. Then those who were inoculated had instructions to let me know if there was any sickness among them. Then I had my sepoys and the servants at the burial and burning grounds always from the beginning of plague, and they brought information if my other people failed to give it to me.

25,431. How did your subordinates and the sepoys at the burial grounds know whether certain persons were inoculated or not?—They inquired whether they were inoculated and what was the name, and reference was always made to the inoculation registers.

25,432. How are you satisfied that the answers they gave you were true answers?—Because whenever they were ill I used to know it, and gave them medicine as I gave to others also.

25,433. How did you know it?—Generally people came to me running whenever they got ill, and my men always used to go and inquire who was ill amongst the inoculated people. It is necessary to know, first of all, that Daman is a very small area, where it is not difficult to make inquiries, and then I, myself, and my men, know all the people. Then, owing to the cordon (British) which was very strict, nobody was allowed to go out of Daman. It was very easy to ascertain, especially in the first year.

25,434. Did you have a register kept in which each person's name was entered as he got himself inoculated?—Yes.

25,435. After the close of the first epidemic did anybody go round with this register in his hand to every house in the town and see with his own eyes whether the inoculated persons were alive or not?—Yes.

25,436. Who did it?—My men. I have about half a dozen men appointed for the purpose, and, as I said, I was specially interested and anxious in making inquiries during the first year in order that the preventive measure which was entirely a new one, and which I had introduced, may not prove injurious and bring a slur upon me. Then, again, Dr. Haffkine was very particular about the statistics.

25,437. Was this done at the close of the epidemic when people had ceased to die of plague?—No. Then there was no need, because my men who were at the burial grounds used to bring information.

25,438. Out of the first set of 2,200 people, how many got plague and how many died?—26 people died of plague up to May 1897, who were inoculated in the first season of the same year, when Dr. Lyons came to Daman for inspection. All the information was supplied to him by me.

25,439. How many got the plague and did not die?—That I have not got at hand. I have the register, but I have not taken out the figure.

25,440. Now with regard to the second lot; how many of those who were inoculated got plague, and how many died?—There were people who were inoculated in 1897 who died in 1898, and also who died in 1899. Up to date, yesterday, 83 persons have died, out of which 36 died during the first season.

25,441. Of those 2,200 inoculated in the first season, how many died in the first season, and how many in the second, and how many in the third? Then, as regards those inoculated in the second season, please tell us how many died in the second, and how many in the third season?—Of the 2,200 of the first season, 46 died in the first season (1897), 19 in the second season (1898), and two in the third season (1899). Of those inoculated in the second season (1898), 12 died in that season (1898), and four died in the third season. Fortunately, there has not been a single case of death among those inoculated in the third season (1899).

25,442. Was everybody who came to be inoculated in Daman inoculated, or did you reject some people because they were too old or too young?—Yes. Those who were too old, or those who had recent fevers or who had fever, or suffering from any other disease at the time, were not accepted. Then the old people, cripples, and small children under six months, and pregnant women, were rejected.

25,443. Did you observe whether inoculation had any marked effect upon the mortality from causes other than plague?—In the first epidemic, I did.

25,444. What was the effect?—After the epidemic had ceased the health of Daman was marvellously good, as the death register will show.

25,445. I am asking about the inoculated people. Had inoculation a markedly good effect upon them with regard to diseases other than plague?—I have not come to learn of any complaint, and when the inoculated people died, whatever they died of was registered. The register shows they did not die of any disease up to date, except the plague.

25,446. Amongst the 2,200 people inoculated in the first season, have there been, up to date, any deaths from causes other than plague?—Amongst the inoculated I have not found a death from any cause other than plague.

25,447. (*The President.*) I think I heard you say that after the epidemic had disappeared the health of the people seemed to be specially good?—Yes.

25,448. During the second epidemic, was there much sanitary improvement effected in the district?—I used to give disinfectants and fumigation. People had great faith in burning rosin and sulphur, and they were freely given to them.

25,449. Was there any special scavenging or cleaning of the place?—It was not what it ought to be.

25,450. Was there more done than before the plague?—Yes.

25,451. During the epidemic you specially attended to the scavenging?—Yes.

25,452. Did you open up many of the houses in which plague cases had occurred?—Not I; the Government did.

25,453. Were only the houses in which plague cases had occurred disinfected?—Yes. It is being done in a real systematic way this season.

25,454. Did they constitute a large number of the houses?—Yes.

25,455. Therefore, you had been specially active during the epidemic in improving the scavenging, cleansing

* Not printed in the proceedings of the Commission.

the place, and opening up a considerable number of the houses?—Yes. It is especially the case this season under Dr. Pinto, the Special Plague Commissioner.

25,456. And after the epidemic subsided the health of the population was greatly benefited?—Yes. If I am permitted, I should like to say that several cases were treated with living frogs. Living frogs were applied to the buboes. The first frog so applied died within five minutes, the second within 10 or 15 minutes, the third within half an hour, and so on; the fifth frog lived about two or three hours. I have even known it live five or six hours, and the patient found considerable relief.

25,457. From killing these frogs?—Not from killing, but from application. The colour of the frog was changed into a greenish-yellow when dead.

25,458. How are the frogs fastened on to the patient?—They were tied on to the bubo, on the abdomen side.

25,459. With a cloth?—No, without a cloth; they were put on and then bandaged. Some cut the frog transversely, and then applied it dead, and kept it on for some hours and then applied another. This is a sort of root (*handed in*) which was applied by many people, and some found relief. The general treatment which the poor people applied was branding of the bubo. I have reason to believe that many escaped by mere branding than by any other treatment. Then there were one or two marvellous cures. A Parsee woman, while pregnant, got diarrhœa, and had it for a year and a half until she was inoculated. As soon as she was inoculated the diarrhœa disappeared on the third day without any medicine. The head Parsee priest, of Daman, is a gouty man, and used to get very severe attacks very often, lasting over weeks. After he was inoculated the attacks have become very mild and far between.

25,460. How many cases were treated with frogs?—About five.

25,461. Did they all recover?—Three recovered and two died. *Mr. S. M. Damaun-Valla.* 15 Mar. 1899.

(The following letter was subsequently submitted by witness:—I produce a receipt which I have obtained from a native doctor, and which was said to be very efficacious:—

"Recipe for bubonic fever given by a native doctor (raid), Brahmachari Boa Raghranand, residing in Kandavady, Bombay, who has treated and cured hundreds of people with the following medicines:—

"*For External Application.*

℞:

"*Bhilama* (marking nut) cut into small pieces - - - - -	1 lb.
"*Isus* (Incense or Crude Mastic) in coarse powder - - - -	1 lb.
"Wax, in pieces - - - -	½ lb.
"Oil of *Sarsi* (Pongamia Globra) - -	¼ lb.

"Mix together and distil. Apply the distilled oil or ointment as a plaster on the buboes, and ferment them with *Neem* tree leaves (Azadirakhta Indica) mixed with Ajawan and common salt.

"*For Internal Use.*

℞:

"Cow's urine - - -	To be taken in equal parts.
"Juice of *Neem* tree leaves - -	
"Juice of green (*i.e.*, fresh) ginger	

"To be taken when there is fever or not. Dose, ½ oz. for adults once or twice a day. If the fever is very high, give thrice a day. When the fever is less, reduce the dose."

The aforesaid native doctor is well known in Bombay, has great experience of native herbs and medicines, and has cured some very serious diseases. He assures me that he has treated hundreds of cases of plague with the above medicines, and cured most of them.)

(Witness withdrew.)

Mr. Shrinivasa Rau, M.B., recalled and further examined. *Mr. Shrinivasa Rau, M.B.*

25,462. (*Dr. Ruffer.*) I believe you have made some observations on the samples of soil found at depths of 1,420 and 1,620 feet respectively in the Mysore mines?—Yes.

25,463. What sort of soil was that?—More or less pulverised rock.

25,464. Was it mixed with any organic material?—Yes.

25,465. Where did that organic material come from?—I believe it must have been brought in by the miners who went down.

25,466. You do not know whether the micro-organisms which you found there are due to the organic material which was brought in by the miners, or whether they were in the rock itself?—That is so.

25,467. What micro-organisms did you find?—Only four kinds of bacilli, three of which were spore-bearing, and one was non-spore-bearing, but it was motile.

25,468. Did you find anything else?—No.

25,469. I suppose the soil on which the coolie lines are built is full of all sorts of material?—Yes.

25,470. Did you find the plague bacillus?—No.

25,471. Did you find that cockroaches which were inoculated died of plague?—A cockroach which was experimented on died, but I do not think it died of plague. There was no moisture in the bottle in which it was kept, and it must have died of that.

25,472. (*The President.*) Why did you make experiments with cockroaches?—I was specially asked to do so to see whether there was any chance of their carrying the plague.

25,473. (*Dr. Ruffer.*) You fed some cockroaches on plague-infected material, but you did not find that it affected them?—No; at least, on the fifth day after I fed them on infected material they were quite well.

25,474. What are "cyanide tailings"?—Pulverised rock mixed with a solution of potassium cyanide.

25,475. Did you find any micro-organisms in that?—No.

25,476. Did you make any experiments as to the effect of fumes given off by blasting gelatine?—I sent my assistant to make them.

25,477. What did he do?—He simply exposed pure cultures of the plague bacillus to the fumes for five, ten, and fifteen minutes. He opened a cotton plug, and also opened a Petri's dish and exposed them to the fumes. I was not satisfied with the way in which the experiments were done, and I have not drawn any conclusions from them.

25,478. Did the plague bacillus die as a matter of fact?—No.

(Witness withdrew.)

(Adjourned to Friday, March 17th.)

At The Secretariat, Bombay.

SIXTY-SEVENTH DAY.

Friday, 17th March 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT.
Prof. A. E. WRIGHT, M.D.
Mr. A. CUMINE.
Dr. M. A. RUFFER.

Mr. C. J. HALLIFAX (*Secretary*).

Major J. Crimmin, V.C., I.M.S.

17 Mar. 1899.

Major J. CRIMMIN, V.C., I.M.S., recalled and further examined.

25,479. (*Mr. Hewett.*) Can you supplement the figures you gave us at your last examination regarding medical examination of the crews and passengers of ships proceeding from Bombay, first to ports out of India, and secondly, to ports in India?—Since my previous examination on 2nd December 1898, the Port Health Staff examined, up to 15th March 1899, 330 vessels proceeding to ports out of India. They carried a crew of 20,273 and 15,745 passengers. The number of vessels examined and proceeding to ports in India, including Burma, was 22,950. They carried a crew of 169,799 and 218,069 passengers. The inspections in the harbour from 1st January 1897 up to 15th March 1899 show that 51,213 incoming vessels, with a crew of 404,934 and 520,679 passengers, were examined, and that 110,851 outward bound vessels, with a crew of 930,448 and 962,573 passengers, were examined, making a grand total of 162,064 vessels of all sorts, with 2,858,634 souls as crew and passengers. The total outward-bound vessels since 1st January 1897 I have classified into (*a*) those going to Aden, Red Sea, and Europe; (*b*) those to ports out of India, other than Aden, Red Sea, and Europe; and (*c*) those going to ports in India.

	Total Number of Crew and Passengers who left for Aden, Red Sea, and Europe.	Number rejected.	Total Number of Crew and Passengers who left for Ports out of India, other than Aden, Red Sea, and Europe	Number rejected	Total Number of Crew and Passengers who left for Indian Ports, including Burma.	Number rejected.
In 1897 - -	56,448	181	32,862	206	621,404	2,935
In 1898 - -	57,988	552	33,705	547	830,135	13,812
From 1st January 1899 until 15th March 1899 -	18,711	107	9,118	139	282,750	6,532
Total -	133,147	840	75,685	892	1,734,289	23,279

Total number of outward bound crew and passengers - - - 1,943,122
Total number of rejected at the examinations - - - - 25,011
Total number of plague cases found among outward-bound crew and passengers - - - 243*

25,480. Can you give us information to show the number of persons you prevented from sailing on outward-bound vessels?—The number prevented from sailing on outward-bound vessels since 1st January 1897 up to 15th March 1899, is 840 to Aden, Red Sea, and Europe; 892 to ports out of India, other than the above; and 23,279 to ports in India.

25,481. How many of these people got plague?—The number of outward cases that we know of is 243. The total number caught at the outward and inward inspections, as well as in harbour craft up to date, is 374. The number of plague cases I have given do not represent the total number prevented from sailing, because in the early days we had no camps to send the rejected to. They were turned into the city, and lost sight of.

25,482. Does your examination, in your opinion, act as a deterrent?—Yes, very much. Nowadays we get very few fully developed plague cases. In the early days we got fully developed cases; but since the people found our inspections were so strict they would not run the risk of being detained at the examinations. A person may have a rise of temperature—99° or 100° F., and he or she is rejected and sent to a camp. If the temperature falls to normal he is let out. If not he is kept until we are certain that the fever from which he is suffering is not due to plague. They have an idea that we knew when they came from a plague-infected house, and that they would be detained if they suffered from fever.

25,483. Does the fact that you have discovered and stopped a certain number of persons who have subsequently developed plague while under your observation, taken with the fact that very few cases have developed after the ship has left port, lead you to infer anything as to the period of incubation?—It is very difficult to give the period of incubation; I have cases in my mind of men who came from non-infected ports, and who developed plague within two or three days after after arriving in Bombay. These men died. There was one the other day that came from London. He was a paid off crew of one of the P. and O. ships. Being paid off he was booked as a passenger, and he came in here on the 25th February and was dead from plague on the 1st March.

25,484. (*Dr. Ruffer.*) Was he a European?—No, he was a native. The only case of plague I have found in a European, in connexion with ship inspections, was the case of a postal official. He was born in this country.

25,485. (*Mr. Hewett.*) I want to ascertain whether you think that the fact that so few cases develop after your examination, when you turn out all the people who have fever, tends to show that the period of incubation is very short?—I believe that in the majority of instances it is from three to five days. That is the period I put it at. Longer periods may be given, but I believe they are, more or less, mild cases and are not detected in the early stages of the illness.

25,486. When you were under examination last, you said you did not disinfect the clothing and the effects of any people proceeding by these ships; do you do so now?—At present we disinfect the clothes and bedding and boxes of all native crews proceeding to all ports out of India, either directly, or by first calling at another Indian port, such as steamers going to Europe *viâ* Karachi.

25,487. What is your method of disinfection?—What we do is as follows:—The new native crews are collected in the disinfection shed by some official from the shipping office who brings a copy of the Articles. Native crews from ships in the harbour are brought by one of the officers of the ship. Roll-call from the Articles takes place so as to make certain that we have the total number of native crew as well as their property. The shed is divided into two portions. In the larger portion, the crews' kit is sorted. The crew dress themselves in the cleanest clothing they have, and the remainder of their clothing and bedding is put through an Equifex stove, and subjected to saturated steam at

* This number is exclusive of 47 cases found on vessels lying in the harbour, and 84 which developed among people arriving from coast ports near Bombay. For detailed monthly figures, *see* App No. X. in Volume I. and App. No. LXXV. in this Volume.

a pressure of 10 lbs. to the square inch. This pressure is said to give a temperature of 239° F., which is said to give absolute disinfection in the case of the most resistant organisms yet isolated. Clothes and bedding are kept in the stove for 15 minutes, and during that time they are subjected to three changes of steam. They are then dried for about five minutes with hot air. Boots and shoes and rain-coats are disinfected with a spray of perchloride of mercury of the strength of 1 in 1,000, or, if they are greasy, they are sprayed with live steam through a hose from the boiler. The crews' boxes are brushed inside and out, or washed, if they are very dirty. They are then rolled about in a large tub containing a solution of perchloride of mercury, 1 in 1,000. The kit and boxes are then passed into a second part of the shed, where they are packed, and are then conveyed to the ship under a Police escort. One of the European Sanitary Police goes on board to see that no bedding is stowed away in the forecastle, fore-peak, or other parts of the ship. Sometimes they say they have no bedding at all, but we make them find it somehow or other. The floor of the shed is then swept, and the sweepings destroyed in the furnace of the stove. I have a copy of the Rules which have been drawn up. They are as follows:—

Major J. Crimmin, V.C., I.M.S.

17 Mar. 1899.

RULES for DISINFECTION of KIT at PILGRIM SHED.

I. The boxes and kit of crews to be collected and placed in the southern half of the building.

II. The Officer in charge of the disinfection should see that the entire kit, clothes, and bedding, and all the boxes of the crew are produced for disinfection. This can be ascertained by having a roll-call from the ship's articles. Each man, as his name is called, should point out his property.

III. The officer in charge should detail one of the Sanitary Police officers to see that the forecastle has been completely emptied of all kit and bedding, and that kit has not been concealed in cupboards, forepeak, stokehold, or other places on board.

IV. All clothes, including those worn at the time, and bedding, should be passed through the stove.

V. Fifteen minutes should be given for disinfection with steam at a pressure of 10 lbs. The steam at this pressure will have a temperature of 239° F. There should be three changes of steam during the 15 minutes, and 5 minutes should be taken for drying with hot air.

VI. The following articles need not be put through stove:—Leather goods, books, velvet, silks, rain-coats, and such other articles which, in the opinion of the Medical Officer, it is unnecessary to disinfect, such as clean white clothes, ironed shirts, &c.

VII. Leather goods should be sprayed with perchloride of mercury, or, if greasy, steamed with carbolised steam.

VIII. The boxes should be brushed inside and out, and then disinfected with perchloride solution, 1 in 1,000. When this has been done, they should be moved to the north side of the shed to receive disinfected kit.

IX. The kit, when disinfected, should be placed in the north side of the shed, packed there and conveyed on board the ship under escort.

X. A certificate, showing the number of saloon, deck and engine-room crew, whose kit has been disinfected, should be sent to the office, so that it may be attached to the vessel's papers for the information of the Examining Medical Officers.

XI. Crew should be advised to wear shoes or boots when on shore, and should clean their feet on returning to the ship at all times.

XII. When the disinfection of kit is finished, the floor should be swept and the sweepings destroyed in the furnace.

(1.) In order to meet the letter and spirit of the Venice Convention, the crews may be examined in the shed while the kit is being disinfected. The names of any of them who have a marked rise of temperature should be taken down and sent to the office.

25,488. Have any cases of plague been detected recently on steamers going to Europe after their departure from Bombay?—No, I do not know of any.

25,489. A statement was recently made in the newspapers that one or two cases had developed on board the *Caledonia*: can you give us any information as to this statement?—At our examination, on the 19th November 1898, we found a man with fever. He was sent for observation, and the doctors in charge of the hospital reported that it was a case of plague. The information was telegraphed to Suez by Government, and on the arrival of the vessel at that port two native crew suffering from fever were removed from the ship. Reuter telegraphed, as an item of news, that they were plague cases. I wrote to Egypt for details of the cases, and at the same time asked for a list of plague cases imported from Bombay during the year 1898. The President of the Quarantine Board replied that neither of the men removed from the *Caledonia* could, in his opinion, be considered to have developed plague, and further that no genuine case of plague had been imported from Bombay during the year. I have the letter here and can read extracts from it.

25,490. (*Dr. Ruffer.*) By whom is it signed?—It is signed by Dr. Cathcart Garner. He says: "The ship, "on arrival at Suez, was disinfected and allowed to "proceed through the canal in quarantine." He goes on to say: "The first of these cases which I have "described as 'slight,' was up and about the next day, "and the temperature normal. He had a small simple "gland only in the axilla." Then he describes the other, and says, "This case has been treated all "through as 'suspicious,' although considering the "absence of certain clinical symptoms together with "the absence of bacteriological confirmation, I am "inclined to believe it was not really a case of "plague."

25,491. (*Mr. Hewett.*) Have any cases of plague occurred on ships going from here to Rangoon?—During the present epidemic which commenced in December 1898, only one case of plague, as far as we know, has got away from Bombay on a vessel bound to any port outside the Bombay Presidency. This was a native cook on board the *Booldana*, which left this port on the 18th of January 1899. At the time of the inspection of the *Booldana* one of the saloon-crew—a native cook—was missing. It now turns out that the missing cook was at the time suffering from fever on shore and did not like to face the inspection. He died of plague on shore a few days after the vessel sailed. The man who developed plague on board after leaving this port was another native cook who we now find resided in the same house as that in which the first cook who died came from. The second cook, who had plague on board, was therefore a contact. That is the only case, so far as we know, that has got outside the Bombay Presidency during the present epidemic.

25,492. Has any case of plague got by sea from Bombay to Ceylon?—No, it was another of those cases reported by Reuter. We made inquiries, and we found he was a man who went by land from Bombay to Tuticorin. He embarked at that port for Colombo, and on arrival he was found to have an enlarged gland and fever. I presume the doctors segregated him as a precautionary measure so as to be on the safe side. It was admitted later on in the newspapers that it was not a case of plague. The man did not die.

25,493. Have you heard this from Ceylon?—Yes; I hand in a copy of the letter from the Port Surgeon, Colombo, saying that it was not a plague case, as follows:—

"Port Health Office, Colombo,
"SIR, 25th February 1899.

"I HAVE the honour to acknowledge your letter No. 307, of 1899, dated 14th February, and to inform you that the case referred to occurred at Galle, and has been officially pronounced to be not one of plague. The patient, Carolis Jayesuria, travelled to Ceylon by way of Tuticorin, and passed through Colombo after disinfection. He was treated at Tuticorin for venereal disease, and the glands of the groin had evidently enlarged sympathetically.

The Port Health Office,
Bombay."

25,494. Is there any trade between the port of Bombay and Madagascar?—There has been some trade, apparently. I find that the last steamer which left Bombay for ports in Madagascar, either directly or by first calling at an intermediate port, sailed on the 9th of August 1897. She had a doctor on board, and during the voyage one death took place. This is certified in the log-book to have been due to paralysis, 41 days after leaving Bombay, and after an illness of 30 days. As far as we know plague broke out at Tamatave, in November or December 1898, that is 15 months after the last steamer left Bombay for

Major J. Crimmin, V.C., I.M.S.

17 Mar. 1899.

Madagascar. I have a special report on the subject drawn up by Dr. Evans of my staff, which I hand in.*

25,495. Can you give us any facts about plague on the *Bhundara*?—The agents of the *Bhundara* say there were seven cases of plague during the voyage, of whom five died, and in addition there was a death certified to be due to acute lobar pneumonia. The first death took place on the 16th December 1898, the day after leaving Karachi. It took place among the coolies from some part of the North of India. There were no cases among the crew who left Bombay, and there was no illness of any kind resembling plague among the crew from the time they left Bombay until they returned to India *viâ* Colombo.

25,496. You have ascertained that from the agents?—Yes, and I hand in a copy of the log-book of the vessel, as follows:—

* *See* App. No. LXXVI. in this Volume.

VOYAGE No. 121.

COPY of OFFICIAL LOG, S.S. *Bhundara*

(*See Note at end of Copy of Log Book.*)

Date.	Entry.
16.12.98 5.30 P.M.	1. A railway coolie named Alla Ditha died from hyperpyrexia, and was buried at 8.5 p.m. by his co-religionists. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
20.12.98 6 A.M.	2. A railway coolie named Navab died from acute lobar pneumonia, and was buried at 8.45 a.m. by his co-religionists. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
20.12.98 10 A.M.	3. A railway coolie named Essa died from uncertain causes, whether cholera (sporadic) or plague, symptoms pointing to either or both, more towards the latter, and was buried at 10.45. a.m. by his co-religionists. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
20.12.98 10.30 A.M.	Effects of Essa (deceased) were destroyed. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
20.12.98 11 A.M.	After burial of Essa, the two cabins set aside for the hospital in the port alleyway, and one other second-class cabin next thereto, were thoroughly washed out, fumigated, and disinfected. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
21.12.98	4. A railway coolie named Jalal Deen died. Cause of death uncertain, whether cholera (sporadic) or plague, symptoms pointing to either or both, more towards the latter, and was buried by his co-religionists at 10 p.m. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
21.12.98 10 P.M.	Effects of railway coolie Jalal Deen were destroyed. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
23.12.98 9.10 A.M.	5. A railway coolie died, Feroz Khan. Cause of death plague, and was buried at 9.45 a.m. by his co-religionists. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
23.12.98 9.50 A.M.	Effects of Feroz Khan (deceased) were destroyed. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
24.12.98 6 A.M.	6. A railway coolie named Maula Dad died. Cause of death plague, and was buried by his co-religionists at 6.25 a.m. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
24.12.98 6.25 A.M.	Effects of railway coolie, Maula Dad (deceased), were destroyed. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
24.12.98	After the burial of the above, the cabins used as hospital were washed out with carbolic acid solution, and all bedding destroyed. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
28.12.98 1.30 P.M.	Fumigated No. 1 'tween deck with tar and sulphur, all ports, ventilators, and hatches closed whilst under fumigation for two hours. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
29.12.98 2 P.M.	Fumigated No. 2 'tween deck for two hours with tar and sulphur. Ports, ventilators, and hatches closed whilst under fumigation. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
30.12.98 2 P.M.	Fumigated 'tween deck alleyways with tar and sulphur for two hours. Ventilators, ports, &c. closed whilst under fumigation. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.

Date.	Entry.
31.12.98 2 P.M.	Fumigated No. 3 'tween deck for two hours with tar and sulphur. Ventilators, ports, and hatches closed whilst under fumigation. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
1.1.99 2 P.M.	Fumigated No. 4 'tween deck for two hours with tar and sulphur. Ventilators, ports, and hatches closed whilst under fumigation. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
4.1.99 11 A.M.	'Tween decks and alleyways washed with a solution of Jeye's fluid and whitewash all over the deck and three feet up the sides fore and aft. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
4.1.99	Lascars' and fireman's forecastles washed with Jeye's fluid and quicklime solution. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
5.1.99 2 P.M.	All flooring in the first-class saloon, also ship's bilges, washed with a solution of Jeye's fluid and quicklime. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
1st to 5th January 1899.	All clothes, bedding, and effects of coolies in No. 1 'tween decks (where all but one of the cases occurred) were soaked into a hot solution of corrosive sublimate for several hours. The coolies themselves were made to bathe in a similar solution. The plague attendants segregated for a few days, and after the necessary actions being carried out, were allowed to mix themselves up with the others. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
6.1.99 9 A.M.	A fracas occurred amongst the deck passengers, in which two of them were injured about the head. One of the offenders, who was caught red-handed, was tied up and kept on water only during the day, under the supervision of the Commander. He was released at 5 p.m. The injured were attended to by the Surgeon, one being retained in hospital for treatment, and the other, after having his wounds dressed, being discharged. Signed—P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
18.1.99	Paint work on upper deck. Saloon and second-class cabins all scrubbed round with carbolic powder. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
20.1.99	Boats used for landing passengers scrubbed and disinfected with carbolic powder. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
21.1.99	Crews' bedding and effects exposed to the sun's rays for six hours this day. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
22.1.99	Crews', passengers', and ship's dirty linen put into the port and starboard cutters and soaked in a solution of corrosive sublimate, as ordered by Health Authorities, to enable the ship to get pratique. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
22.1.99	Washed the 'tween decks, fore and aft tops, sides, and deck with corrosive sublimate, as per above orders. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
22.1.99	Put corrosive sublimate into all the bilges and pumped them out fore and aft. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
23.1.99	Took the linen out of soak and dried all during the day. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander
24.1.99	Destroyed by fire 40 bundles dry fish marked a.m. or c.a.m. under instructions from the Port Authorities. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer. A. E. STEBBING, Commander.
25.1.99	Destroyed by fire the following packages, under instructions from the Port Authorities, being rat-eaten :— A.M.J. - - 3 Bags Indian Corn. ,, - - 3 Bags Jawaree. B.A.K. - - 1 Bag Jawaree. E.A.K. - - 1 Bag Jawaree. Signed—J. E. SYLVESTER, Doctor. P. H. STUNT, Chief Officer, A. E. STEBBING, Commander

Major J. Crimmin, V.C., I.M.S.

17 Mar. 1899.

The Medical Officer's Register shows six deaths from plague and two recoveries according to the following extract from the Register of the *Bhundara* on the voyage from Bombay to East Africa, *viâ* Karachi:—

No.	Names.	Disease.	Remarks.
3	Alla Ditta	S. Plague	16th. Died.
4	Nawab	S. Plague	16th. Died 20th.
5	Esa	Plague	19th. Died 20th.
6	Jalal	Plague	21st. Died 21st.
7	Feroz Khan	Plague	23rd. Died 23rd.
8	Mooladad	Plague	24th. Died 24th.

Besides the above, two more railway coolies are shown to have been admitted suffering from plague on the 25th December, Surbar Kutal, temperature 104·2; and Khuda Bux, temperature 103·4. Both had tender inguinal glands, and both recovered.

25,497. So that all the cases occurred among the coolies?—Yes, all occurred among the coolies, none of whom had left Bombay. The first death, as I say, took place on the 16th December 1898, the day after leaving Karachi. The second death occurred on the 20th December, the third on the 20th, the fourth on the 21st, the fifth on the 23rd, and the sixth on the 24th of December.

25,498. Do you wish to say anything with regard to some previous evidence which has been given here about the discharge at Mandvi in 1896 of the cargo of a ship laden with wet grain?—Dr. Weir, in his evidence on the second day, refers to a ship laden with wet grain, and states that notwithstanding his protest, the grain was landed and stored at Mandvi, and that a large number of rats died.* I remember the ship very well. She was the *Knight Companion*, which returned to Bombay after meeting with rough weather in 1891. The agents reported that the grain cargo was damaged and stinking badly, and wished the Port Health Officer to condemn it, apparently for insurance purposes. We stated that we had nothing to do with damaged cargo, and had no power to condemn it, and suggested, if it was stinking, that it would be advisable to send it out to sea on an ebb tide. The agents then consulted the Municipal Health Officer, and afterwards, presumably with his knowledge and permission, sent the grain cargo into the city. It would appear that the Municipal Health Officer has, or had, no power to order the destruction of bad or damaged food-stuffs unless actually exposed for sale as human food. Most of this cargo, I remember, was boiled down to make size of for stiffening piece-goods.

25,499. (*Dr. Ruffer.*) How do you ascertain the temperature in your steam sterilizer?—It is guaranteed by the constructors.

25,500. Have you ever made any comparative experiments?—No. I do not think there is an electric signal thermometer available in India. The results of the experiments showing the temperature at various pressure are given in a book of instructions sent with the sterilizer.

25,501. Yo do not take the temperature at each disinfection?—No; it is impossible, unless we have a patent signal thermometer, which I understand are very liable to get out of order.

25,502. (*Mr. Hewett.*) Is there anything else you wish to bring before our notice?—I understand some people are rather sceptical as to the way in which we carry out harbour inspections, and the success which has attended them. I should be delighted if the Commissioners would give me an opportunity of accompanying them around, so that they can verify for themselves what is done.

25,503. Have you any facts to show that certificates of inoculation are tranferred from person to person?—We have come across certificates, occasionally, where the description in the certificate does not correspond with the person presenting it.

25,504. Can you give specific instances of this?—As a specific instance, I remember one case which was brought to the notice of Government in connection with another matter. The card showed that Janki Dhakoo, a woman, age 40, was inoculated on 15th February 1899. The card was presented on the 20th February by a lad of not more than 17 or 18 years of age.

25,505. Will you please give us the number of deaths that occurred in 1895 and 1896 on board ships coming to Bombay from Hong Kong, with details of each case of death that occurred?—I cannot give deaths in those years, except for part of 1894, when plague was epidemic in Hong Kong. I have the counterfoils of the pratique book for 1894, which showed that 11 vessels arrived during the time that restrictions were in force against arrivals from Hong Kong, with a total of 1,269 crew, and 342 passengers from Hong Kong between the 29th June and 25th September 1894. During the voyage, three deaths occurred, and none of the persons who died came from Hong Kong. It is stated on the counterfoils of the pratique book, that many of the 11 vessels refused to take native passengers from Hong Kong. The log-books of six of the ships are filed in the Bombay Shipping Office, and the following is the history of the three cases who died:—

Case I.—The *Clyde* left Hong Kong on 2nd August, arrived Bombay 19th August. Mohamed Abdulla died from malarial fever on 17th August. He was transferred at Colombo from the s.s. *Shanghai*, which was on a voyage homeward bound from the East.

Case II.—The *Rosetta* left Hong Kong 16th August, arrived Bombay 3rd September. Bellal Jeewa died on 2nd September from beri beri. He was transferred at Colombo from the s.s. *Australia* which was on a voyage homeward bound from Australia.

Death 3.—The *Rohilla* left Hong Kong on 13th September, arrived Bombay 1st October. Abdulla Sallim died on 27th September from pneumonia. He was transhipped at Colombo from the s.s. *Mirzapore*, which was on a voyage outward bound from London to Calcutta.

The above three deaths had been certified to by the Surgeons on board. All the 11 vessels had doctors on board, with the exception of the *Kong Bing*. This latter vessel had no passenger leaving Hong Kong or on arrival at Bombay.

The above information and the fact that none of the intermediate ports became infected is against the hypothesis that plague was imported into Bombay from Hong Kong by human agency.

25,506. A case, supposed to be plague, has just occurred in a man who has arrived in a ship from Hong Kong, and is at the Modi-Khana Hospital. Will you please let us have particulars about that case, including the following, viz.:—

(1) When the ship in which the man came left Hong Kong;
(2) Where it touched;
(3) When it arrived here;
(4) How long the man was reported ill before arrival;
(5) Whether there was a doctor on board or not;
(6) Whether the man's illness was noted in the log-book or not; and
(7) How the case has been diagnosed to be plague?

—(The following particulars were supplied later by witness):—The following is a statement of information obtained from the Captain of the *Bormida*:—

Questions.	Answers.
"1. When did the *Bormida* leave Bombay on the last occasion, and for what ports?	She left Bombay on 28th January 1899 for Singapore and Hong Kong.
"2. Was her native crew's kit disinfected before leaving Bombay?	No. There was no such rule in force at the time.
"3. What crew and passengers did she take with her on the 28th January 1899?	Eighty-four crew and 20 passengers.

* *See* Question No. 996.

Major J. Crimmin, V.C., I.M.S.

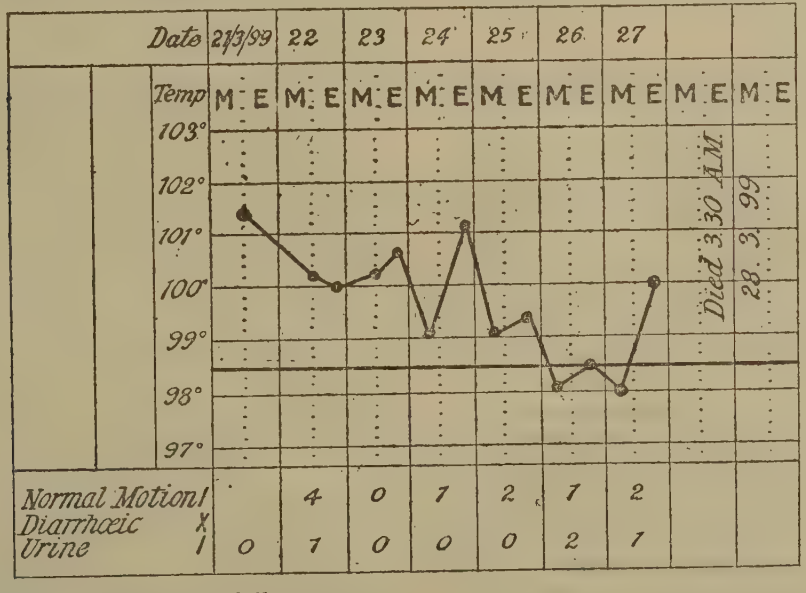
17 Mar. 1899.

Questions.	Answers.
"4. What illness did the crew and passengers suffer from between Bombay and Hong Kong?	None.
"5. When did the *Bormida* arrive at Hong Kong, and how long was she at that port?	On 24th February, and remained there for four days.
"6. When did she leave Hong Kong for Bombay, and with what number of crew and passengers; giving the nationality to which they belonged?	Left on 28th February with the same number of crew, and with 366 passengers Chinese, including two Europeans.
"7. What ports did the vessel touch at between Hong Kong and Bombay, giving dates?	She touched Singapore on 6th March and left on the 9th. She touched Penang on the 11th morning, and left in the evening the same day.
"8. What illness did the crew and passengers suffer from on her voyage to Bombay from Hong Kong?	None whatever.
"9. When and where was the Chinaman cook Kwoknam shipped?	From Hong Kong.
"10. Was he examined before the vessel sailed from Hong Kong, and by whom?	Yes, he was examined along with others by the Health Officer of the Port.
"11. Was any medical examination of the crew and passengers made by the Port Health Authorities at Hong Kong, and on what date?	Yes, on the 28th February, the day of sailing at 11 a.m.
"12. On what date did Kwoknam commence to suffer from fever?	The first notice of his illness was made by the ship's doctor on the 21st March.
"13. Was he on shore at Hong Kong, and if not, had he an opportunity to go on shore if he wished?	He was, of course, on shore, because he came on board from Hong Kong, replacing one Chinaman in service on board.
"14. What cargo did the vessel take in at Hong Kong?	Sugar, camphor, chinaware from Hong Kong, and planks, rattens, tin, and coffee from Singapore and Penang.
"15. Did any rats die during the voyage?	None.

G. DELAYN,
Bombay, Commander S.S. *Bormida*.
24th March 1899."

The Italian s.s. *Bormida* left Hong Kong on 28th February 1899, touched at Singapore 6th March, Penang on 11th March, and arrived at Bombay on the evening of 20th March 1899. Two days before she left Hong Hong a Chinaman named Kowk Nam was shipped as a cook. There was a medical practitioner on board, but no reliable history can be obtained about this Chinaman cook, and no entry of his being ill was made in the log-book. On inquiry on board some of the Chinamen said that the cook had slight fever for two days, and some said for seven days, while others said he had buboes from the time he left Hong Kong. It could not be ascertained if the man was in the habit of smoking opium to excess. On arrival in Bombay the man's temperature was 101·4° F., and he had enlarged glands in each inguinal region as well as an old sore below the navel. He became delirious on the 21st March, and was taken first to a non-plague hospital, where he was refused admission. He was then admitted into the Modi-Khana Plague Hospital, where the case was reported as one of plague. A copy of the man's temperature chart is as follows:—

Name, Kwok Nam; Sex, Male; Age, 30; Caste, Chinese; Occupation, Cook.



The clinical notes on the case are as follows:—

R. No. 2,412.
Name, Kwok Nam.

Date, 21.3.99.

Age.		Disease.	Duration of Disease.	Occupation.	Locality of Residence.	Caste.
Years.	Months.					
30	—	Plague. 1 bubo L. groin, 1 bubo R. groin.	7 days -	Cook - -	S.S. *Bormida* -	Chinese.

Major J. Crimmin, V.C., I.M.S.

17 Mar. 1899.

Clinical notes—*cont.*

Date.	Symptoms.	Prescriptions.
—	Admitted into the hospital with fever and gland in both the groins. The patient is delirious and violent. Pulse is weak and frequent. Has an ulcer over the abdomen. The gland in the left groin is larger than the right, it is very tender. The relative of the patient says that he is suffering from fever for the last 7 days, became delirious this morning. The duration of the gland and ulcer is unknown. Came from s.s. *Bormida* from Hong Kong.	℞ Mist. Strych. ℥ iv. Sig. ℥ i every 4 hours. ℞ Morphia grs. ½. Liq. Strych. m. v. Fiatinjectio. 6.40 p.m.
22nd	Is delirious, but less than last night. Gland in the left groin is hard and prominent. Tongue is red at the tip. Pulse weak and quick. Culture taken by Dr. Liston from bubo in left groin. This culture showed a pure growth of bacilli pestis.	22nd. do.
23rd	Is quiet. Rigbt bubo more enlarged. Culture taken from an incision near the ulcer.	23rd. do.
24th	Slept fairly, is conscious, pulse frequent and fairly strong. Tongue is red at the tip, coated at the back. The ulcer is drying. Cut over the left gland is ulcerated.	24th. do.
25th	Is quiet. Pulse fairly strong. Slept fairly. Tongue is coated. Eyes are injected.	25th. do.
26th	Is quiet. Ulcers are drying. The gland in the right groin getting soft. Tongue coated.	26th. do.
27th	Is weak. Does not take nourishment properly. Pulse soft. Died 3.30 a.m. 28.3.99.	27th. do.

It will be seen from the chart and notes that the temperature fell to 99° on the 24th, and that he was reported to be conscious. As the case was rather a peculiar one, I asked the Senior Medical Officer to have a bacteriological examination made. This was done on the 22nd and 23rd March, and it was reported that plague microbes were found. The bacteriological report is as follows:—

"Bacteriological and Clinical Report on Chinaman from Hong Kong, landed in Bombay 21st March 1899 suffering from Fever.

"On 22nd March I received instructions from Dr. Wilkins to make a bacteriological examination of the case of a Chinaman who had come from Hong Kong suffering from fever, and who was then lying at the Modikhana Plague Hospital.

"I saw this patient on the afternoon of the 22nd March. He was then delirious and talking in some unknown language and in broken English. His speech was not slurred or stuttering. His pulse was rapid, large, but soft. The tongue was flabby, coated with a thick white fur. The conjunctivæ were not injected. Temperature in axilla 100·2.

"Just below the umbilicus occupying the middle line but somewhat more inclined to the left side was an ulcer about ¾-inch broad by about 1¼ inches long (the longest diameter being vertical). The centre of the sore was occupied by a black slough; the edge of the sore was slightly elevated and infiltrated, and of a red colour. The infiltration did not extend for more than half an inch from the edge of the ulcer. In either groin an enlarged gland could be detected, largest on the left side. An incision with aseptic precautions was made into the gland in the left groin and with a platinum needle, agar tube cultures were made.

"The patient was again examined on the 23rd. Delirium was not so marked, he was weaker and the glands in the groins were decidedly larger, otherwise his condition was much as before. An incision was made into the infiltrated area at the side of the ulcer in the abdominal wall and agar tube cultures and blood films prepared therefrom. The blood films when stained showed one or two bacteria morphologically resembling plague bacilli.

"On 24th, an abundant growth was evident in the agar tubes obtained from the bubo on 22nd, the characters of the colonies, their rate of growth, and microscopical specimens resembled plague, but to ensure the diagnosis a mouse was inoculated intraperitoneally on the 24th with one drop of a broth emulsion from one of the tubes planted on the 22nd. The mouse died on the 25th. Plague bacilli abundant in all the organs, but particularly in the liver.

"On 25th the growths in the tubes planted from the edge of the abdominal ulcer showed a mixed growth of staphylococcus albus, and plague bacilli.

"The previous history of this case is as follows:—The patient was a cook on board the S.S. *Bormida* which left Hong Kong on the 5th March, calling at Penang and Singapore on the way to Bombay. Seven days before arrival in Bombay he began to suffer from fever. The duration of the ulcer in the abdomen was unknown, but from clinical evidence must have been of at least seven days' duration before it was seen by me on the 22nd. He began to suffer from delirium on the 21st, his temperature being 102·4 at 7 a.m. on that date. After landing he was first taken to the Goculdas Tejpal Hospital, and then transferred to the Modikhana. I am indebted to Dr. Turkhud, in charge of the Modi-Khana Plague Hospital, for the above information.

Wm. Glen Liston, Lt. I.M.S.,
attached Indian Plague Commission."

The man died on the 28th March, or six days after the first bacteriological examination was made. As the ship had a crew of Italian and Chinese, it was difficult to obtain any reliable information regarding the Chinaman cook. For this and other special reasons I would recommend that no conclusion be arrived at regarding plague. There was another Chinaman on the same vessel at the same time with a temperature of 102° and an old left inguinal bubo. We took him out of the vessel on her departure from Bombay, not that he was a plague case, but so that the vessel may not run the risk of quarantine at a foreign port in the event of the Chinaman being found with fever and a bubo. We know all about this man's old bubo, as the fact had been noted by us in the official papers when the vessel was leaving Bombay on a previous occasion. The man was all right next day, and has continued so.

(Witness withdrew.)

Mr. J. H. Du Boulay, I.C.S. recalled and further examined.

Mr. J. H. Du Boulay, I.C.S.

17 Mar. 1899.

25,507. (*The President.*) There are a few other points about which we require some further information from you?—Certainly.

25,508. (*Dr. Ruffer.*) Can you tell me how many Plague Hospitals there are in Bombay under the Municipality?—The Arthur Road, the Mahratta, the Modi Khana, and the General Muhammadan are those directly under the Municipality, and we have considerable control over several others—I mean we have greater control over one or two others than we have over the absolutely private hospitals.

25,509. What is the medical staff of the Modi Khana hospital?—Dr. Turkhud is in charge of it. There are six nurses, three English and three local.

25,510. How many patients are there?—Seventy-two plague patients at present.

25,511. And how many other patients?—Forty-six observation and other diseases.

25,512. Practically about 120 patients?—A hundred and eighteen, yes.

25,513. Has the doctor in charge got any other duties besides his hospital duties?—I think he has duties in connexion with the Leper Asylum.

25,514. Do you think it is possible for a man to look after 120 patients and do duty somewhere else as well?—He only spends a few hours there, but I am hardly competent to give an opinion about a medical man's ability.

25,515. Do you think it is possible?—He is obviously away for a certain number of hours a day, and he cannot be attending to patients while he is away.

25,516. How many nurses are there?—Six.

25,517. Three day and three night nurses?—Yes, I think that is how it is arranged. These arrangements are all under Colonel Wilkins, and they do not directly come to me.

25,518. How many Hospital Assistants have you got?—Two.

25,519. Would you go to the next hospital?—The Arthur Road. The Medical Officers are Dr. Choksy and Dr. Fraser.

25,520. Does Dr. Choksy practice as well as look after the hospital?—I hear of cases where he attends on plague patients.

25,521. Has he any other duties besides at the Arthur Road Hospital?—I do not know of any others. He used to be in charge of the Leper Asylum, but he has given that up.

25,522. What is the total number of patients?—One hundred and thirty-four plague cases, and one hundred and five observation and other diseases; total 239.

25,523. The ordinary staff consists of Dr. Choksy and Dr. Fraser: anybody else?—There are no other doctors. There are 13 nurses, four Hospital Assistants, two compounders, and 46 ward boys.

25,524. Are these Hospital Assistants allowed to do any work outside the hospital?—I think they practically never leave the hospital.

25,525. Will you go on to the next?—The Mahratta Hospital has got Dr. Dhargalker and Dr. Lam, and there are two people who are called House Surgeons—they are not fully qualified—Suntoodji Ramji and Eknath Hate. There is also a Vaidya who takes charge of the considerable number of patients who prefer native treatment.

25,526. How many plague patients are there?—In the Mahratta Hospital 222 plague cases, and 54 observation and other diseases.

25,527. Do you think the medical staff is sufficient for that number of cases?—I think so. There are three Hospital Assistants, and three medical students. Of course the people do not like excessive attendance, they prefer being left alone as much as possible, that is the great thing in the Mahratta Hospital.

25,528. That is a hospital where they do the bathing treatment chiefly?—Yes, they prefer the Mahratta Hospital to the Arthur Road.

25,529. What is the other hospital?—The other is the Northbrook Gardens. There is only a native hakim in charge of that. That is a Musalman hospital.

25,530. How many nurses are there?—I do not think there are any nurses there. There are three ayahs; they do not like English attendants.

25,531. In going round the hospitals, I noticed that a great number of the patients are tied up in the beds: do not you think that could be prevented if you had a larger number of nurses?—If you had a very enormously increased staff, it could be done. We should have to have a nurse for every two or three patients.

25,532. Is it not a very painful process to be tied up in bed when you have fever?—It has never been done to me. I think the patients are mostly delirious.

25,533. Do you think it is a pleasant process?—The nurses, I presume, would merely hold them instead of tying them.

25,534. I want to ask you about disinfection. You disinfect a good deal with perchloride of mercury?—Almost entirely.

25,535. What steps did you take to see that the perchloride of mercury used was of good quality?—I have had one specimen analysed within the last two or three months, and that was practically pure.

25,536. It was never analysed before two or three months ago?—I do not know what the Plague Committee did. I notice in their report that they took frequent steps to have it analysed. The perchloride of mercury here is received in packets from the manufacturer. If there is any break in the seal, the sample is rejected.

25,537. How long ago is it since the samples were analysed?—Within the last two months.

25,538. What was the result of the analysis?—The perchloride was practically pure.

25,539. What impurities did it contain?—That is all I have got from the Chemical Analyser—that it was practically pure.

25,540. Have you ascertained the strength of the solutions which are used?—Yes, I have had samples analysed from time to time.

25,541. Could you give us the result of those analyses?—One was made by Professor Wright, taken from a bucket containing 1 in 3,000.

25,542. Was it acid? The solution that you used is supposed to be acid?—Yes, the solution was slightly acid.

25,543. What is the quantity of acid that it is supposed to contain?—About 1½ to 1 of perchloride.

25,544. It should be strongly acid, should it not?—I cannot give an opinion about that.

25,545. Could you give us the result of the other analyses which you have?—I got from the Chemical Analyser an opinion on the point of acidity. He suggested the use of hydrochloric acid one lb., with one lb. of mercuric chloride to make a hundred gallons of solution. The above proportions are correct for pure water. To meet the possibility of ordinary alkaline salt when it is being used, it might be advisable to increase the hydrochloric acid to 1½ lbs. per hundred gallons of solution. That rather strengthens my belief that it is sufficient.

25,546. If it is only slightly acid, it simply shows that the amount of acid has not been added. It should be strongly acid if it contains 1½ per cent. of hydrochloric acid?—I do not know. I think the hydrochloric acid is useful for other purposes, but of course it should be there if you put it in. I went to another district and made some of the stuff myself, and took that out in the district and took a sample of that, as well as of what they were actually using; and that came to 1·206 per 1,000 as the strength of the sample I myself prepared. What they were actually using before, with the preparation of which I had not anything to do, came to ·610 per 1,000. In another case I did the same thing. I made some myself, and took a test of what they were actually using. What I made myself came to 1·475 per 1,000, and what they were actually using came to ·612 per 1,000. In another case I took a test of what they were actually using, and it came to ·7 per 1,000. In another case I took a test of what they were actually using, with some that I prepared myself, and what they were actually using came to ·09 per 1,000; and that which I prepared myself came to 1·08 per 1,000. I think it right to point out

Mr. J. H. Du Boulay, I.C.S.

17 Mar. 1899.

that that district has been without a district officer for some time. These, of course, were tests I took for my own information originally, not for yours. I also took some tests later. After I began taking these tests, and was rather unsatisfied about them, I asked one district officer to put a larger quantity of perchloride in the solution. In taking a test later I prepared a sample myself, as I wanted to see particularly what was the effect of the metal pump which they were using. I took one sample straight from the tube before the pump was put in, and another sample I pumped with a metal pump through a long greased tube in order to see what the effect of the metal was. The pump immediately became covered with silver—mercury I suppose—but the Chemical Analyser reported that both samples were 2 per 1,000.

25,547. The difference would be exceedingly small. Have you anything else?—I have told you of the perchloride I took, and I have just made a rough note of other disinfectants that were tested last year. Carbolic acid powder was tested five or six times during 1898. It was found to contain 13 per cent. of acid. Carbolic acid was tested two or three times, and each time found to be of good quality. In another case there was an analysis of perchlorde of mercury in use taken by Dr. Ruffer which gave 1·25 per 1,000 as the result.

25,548. How did you ascertain the temperature in the sterilising stoves?—By the pressure outside—by watching the gauge outside.

25,549. Do you think that is a good method? Have you ever found that the interior of the bundles of clothing that were put inside, was not up to the proper temperature?—Yes, on the occasion that I went round with you, sir, we found that, but you had to search for these places where the clothing was cold.

25,550. Part of the clothing was cold?—Yes.

25,551. But would it not be better to ascertain the temperature in a bundle of clothing each time; would it not be a more efficient method?—It would be more efficient I think. It was contrary to orders that that clothing was put in in bundles; the clothing ought to have been put in loosely, as is done now.

25,552. (*Prof. Wright.*) What method do you think is the best in your experience of getting information of plague cases while the patients are actually alive? Have you found a system of reports by doctors to be satisfactory?—No.

25,553. Have you found that the system of reporting by volunteers gives you satisfactory results; that you receive information of all the cases of plague that occur?—No, we never had received information of all the plague cases that have occurred before death, but then the cases are very often very virulent, and die in six or seven hours sometimes.

25,554. What do you think about the system of discovering plague cases by house-to-house visitation?—It is absolutely intolerable to the people; that is my experience of it.

25,555. What systems do you at present adopt—the system of getting reports from medical men, and the system of reports from volunteers?—The reports from volunteers; we also find out where every death occurs—not quite every death, but we find out all but about five per cent. of the deaths that occur in the city.

25,556. I am talking about living cases?—Those houses where deaths are occurring come under closer observation by the staff itself; they search those houses. Very often we get a great deal of information from the friends of the patients, and we send the cases to hospital; we also get a good deal of information from the neighbours who object to having plague cases near them; and we get a certain amount of information from spies, and we have all sorts of minor sources of information.

25,557. What percentage of plague cases do you think are reported to you during life? Do you receive information of one per cent. of plague cases by all these means?—It is very difficult to put it in that form straight away; I should have to work it out. I could hardly, without thinking it over and working all the figures out, give you an idea.

25,558. When you find the plague patients during life, what is your policy? Is it not the case that patients were removed to hospital by force?—I know of no occasion where force has ever been used; they have always been persuaded eventually.

25,559. Your policy is to remove them to hospital?—Yes.

25,560. Do you in any case leave a patient behind in his own house?—Occasionally.

25,561. In what cases do you leave him behind in his own house?—If he is moribund; it practically comes to that. Unless the man is certified by a medical expert to be in a very dangerous state he never is left in his house. District officers have a discretion to leave patients at home if proper arrangements for isolation and treatment can be made. It is very rarely exercised.

25,562. Supposing you find great opposition to his removal, then would you under the present system leave him in his house?—Opposition is nearly always backed by a medical certificate that the man is moribund, or in a very precarious condition.

25,563. Do you think it good policy to remove plague patients to hospital; do you think that it arouses much opposition, and leads to much hiding of cases?—I suppose it does, yes.

25,564. Do you think it would be a better system not to remove anybody to hospital, except people who were really anxious to go?—I should say not. I do not know how this infection is spread, but I imagine that the patient in the house is the centre of infection. Most of our houses are big chawls in Bombay, and you cannot isolate patients in those places.

25,565. The advantage of removing them to hospital is that you remove the source of infection, and the disadvantage is that you lead to the secretion of cases. I am asking you to judge whether you think the advantage of removing the source of infection counterbalances the disadvantages which are associated with the secretion of cases?—I do not feel that I am able to pronounce an opinion about that.

25,566. I want to know whether you have arrived at an opinion about it, whether it would be a wiser policy?—I have not arrived at an opinion about it.

25,567. What steps do you take when you leave a patient in a house to prevent him disseminating infection? Supposing you leave a moribund patient in his house, what steps do you take to prevent his becoming a source of infection?—Nothing beyond giving instructions to the people in the house, and beyond talking to them seriously if they disobey.

25,568. There is no system of periodical disinfection of floors when the patient is left behind?—That is occasionally done. The people are told to disinfect, and are given disinfectants to use, but the houses are not disinfected as a rule by our staff in those cases.

25,569. Do you think it would be practicable in those cases to go into their houses and disinfect their floors and walls and clothes periodically, or do you think it would not be practicable?—It would not be practicable. You could not disinfect the most infected part of the room very well; the patient would be lying there, and you cannot very well disinfect his bedding while he is on it.

25,570. You think it would be difficult to do it satisfactorily?—Yes, and there would be a certain amount of opposition too. It would not be so bad as removing them, of course, but they would say, "Why cannot you let us do this?" and there would be a certain amount of opposition.

25,571. Your measures that you take to prevent the spread of infection from living patients consists chiefly of removing them to hospital?—Yes.

25,572. When you remove the patient to hospital do you disinfect the room from which he has been removed?—Yes.

25,573. What steps do you take to prevent infection occurring after a death from plague has occurred?—We go at once to the room and burn all the clothing we find lying about.

25,574. How do you receive information that a patient has died of plague; do you receive the medical reports?—We get from our volunteer agents the same sources of information as we get about living patients, and in addition we have the cemetery reports.

25,575. You have reports from doctors, reports from volunteer agents, and reports from the cemetery?—Yes, and reports from our own staff, and spies, and the Municipal staff.

25,576. How many reports do you get from doctors, private practitioners, of cases of death from plague?—Not a great number, about 30 or 40 a week, or something of that sort.

25,577. That means about five a day, and your mortality may be sometimes 300 a day on the average?—Yes.

25,578. So that that is a very ineffective method?—I am speaking of private practitioners, who are not volunteers; the volunteers work harder.

25,579. Do you think that represents the number of plague cases that are actually attended by doctors?—No.

25,580. You think there is a good deal of secretiveness, and the doctors do not report cases?—I should think so.

25,581. You have your reports from volunteers, and spies, and at the graveyards; will you tell us what is the agency you employ at the graveyard?—There are Hospital Assistants there who ask the symptoms from the people who bring the body, and naturally the people are not in a hurry, as a rule, to say that it is plague, but still there are a certain number who give the information, and as soon as that information goes down to the district the house is dealt with. The Medical Officers visit every house where a death has occurred and make inquiries as to the cause.

25,582. I understand that on one particular day you had a death rate of 391: do you remember how many of those deaths on that day were discovered to be plague by means of this agency at the graveyards and burning ghauts?—I cannot tell you that.

25,583. How many were put down as plague out of that?—I think it was certainly under 200.

25,584. And your normal mortality would be about 80; is not that so?—Yes.

25,585. And probably 310 died of plague?—Yes, about that—there is a good deal of measles now.

25,586. At any rate, it would be about two-thirds of the probable deaths from plague that you find out by these means?—I was going to tell you that we do not accept the cemetery reports as final that such and such a case is plague. My medical men go round to the houses, and make inquiries from the neighbours regarding every death.

25,587. On a day like that you would have 391 deaths; how many of them would be investigated afterwards?—Every death is investigated whether it is put down as plague or not.

25,588. Is a man sent to the houses?—A medical man goes to every house where a death occurs; but of course they know a great number of them before—they are cases that passed through their own hands.

25,589. Do you mean to say that 391 visits were paid by medical men to discover the cause of death?—You would probably have to knock off over 200 to start with, of cases they knew about beforehand. There is a great deal of sickness reported to our medical men beforehand; they know all about those cases, and about all those that they have had to deal with before. They are responsible to go and find out what the cause of death was in every case where they do not already know it.

25,590. There are Hospital Assistants at the cemeteries and burning ghauts, and they write a list of cases?—The cemetery officers merely record the opinions of the people who come with the bodies there. They say, "What symptoms had he and what has he died of?" And from the answers they diagnose cases as plague or as the case may be.

25,591. They send a list then of the deaths that appear to them to have been caused by plague; who does that list go to?—The record of all the deaths is sent to the Health Department.

25,592. Are they sorted out there?—They are sorted out at the Health Department, and the Health Department send the various lists down to the Inspectors.

25,593. Who sorts out the cases of plague?—They do not sort out the cases of plague.

25,594. On the day when there were 391 deaths, a list of the cases would be sent to the Health Department, and 200 of these would be deaths that occurred from plague. What happened to that list in the Health Department?—You insist on speaking of the plague cases; the deaths are all jumbled together; they do not sort out the plague cases there.

25,595. What process takes place at the Health Department?—The clerks sort them out according to the different sections of the city to which they belong, and put down the names and addresses and the causes of death. I have a copy of each section made, which I send to the District Officer responsible for that section.

25,596. Do you send it the same day?—The same night, and he gets to work on it the following morning.

25,597. (*Dr. Ruffer.*) Twelve hours afterwards?—Yes.

25,598. (*Prof. Wright.*) In the Health Office they are sorted out according to the sections in which these deaths occur, and a list is sent to your Divisional Officers. What steps are then taken?—They check these by their registers and books.

25,599. What registers and books?—They keep registers of all sickness and deaths that they hear of in their district, and of all plague cases. If he has a plague case, and removes it to the hospital, and the case dies, the death appears in the cemetery list, and it comes back to the district office, and he looks at the book to see if he has treated that man or not. If he has, there is no further action to take, as he has already disinfected the place when he took the patient to hospital. Similarly when a death occurs, although he may not have heard of the sickness, he has very likely heard of the death before the cemetery list comes in, and he may have gone there and disinfected the place at once, if he thought it was plague. If that has happened, he ticks it off, and it is disposed of. The cemetery list would come to him 24 hours later, but every death in the city, which is not sent from a Plague Hospital, or sent with a certificate from a volunteer, is supposed to be caught by the police, who give earlier information than is received from the cemetery.

25,600. I have not understood this yet. The list goes to the Health Office, I understand, and then it goes to the Divisional Officer; the Divisional Officer looks through the list of the day, and he recognises the cases of people whom he has previously dealt with?—Or there may be a large number that may not require disinfection—who were not plague.

25,601. There are a large number he may not have heard of before, and who are on this list?—They are not a large number; I should say about ten in thirty.

25,602. About 30 per cent. of the cases were not heard of before?—Yes.

25,603. He may have received reports of two-thirds of the sickness occurring in Bombay?—Of the deaths.

25,604. This is the first notification of the deaths?—No, I have said that the police also give us information of deaths. As a funeral party goes along the street, a policeman will go up and inquire where they came from.

25,605. To whom do the police give the information?—To the Divisional Officer through the Registration Office. There are recording offices all over Bombay—seven or eight. The police instantly give information there, and the recording stations pass it on to the Divisional Officers.

25,606. You have a further record of deaths supplied by the police?—I do not call it a record; it is merely an auxiliary means of getting early information of deaths.

25,607. Does that go to the Health Office?—No.

25,608. How does that get to the Divisional Officer?—It gets to him from the recording station. There are seven or eight recording stations which receive the information from the sepoys who find the house, and this is sent on to the District Officers.

25,609. That is information of death; it does not convey any information as to the cause of death?—None whatever.

25,610. I mean in a large majority of these deaths the Divisional Officer does not know whether they are due to plague or not,—he does not know anything about the cause of death; is not that so?—Yes, there are a large number of cases when he only learns the cause of death by subsequent inquiry. I wanted to point out to you that this information from the police is prior to the information that they give us in the

Mr. J. H. Du Boulay, I.C.S.

17 Mar. 1899.

cemetery, so that when District Officers receive information from the cemetery they have already inquired into the death. They have only a few left on the fever sheets.

25,611. Does the Medical Officer visit each house in which a death has occurred?—Yes.

25,612. In the case of the 391 deaths on that day, a medical officer would have visited each house and made a report?—Yes, but of course there are a certain number of cases of death that we cannot trace, owing to wrong addresses being given.

25,613. When he has not seen a patient, he has only been able to make inquiries from the relatives. The information with regard to the cause of death is from inquiries made from relatives at the graveyard, and inquiries from relatives at the house?—Yes; but there are a number of sick people, and dying people, and dead people, either of plague or not of plague, whom the medical officers have seen before the body is removed to the cemetery.

25,614. Those who have been seen during life are a very small proportion of the total cases, are they not?—I could not give the proportion; it would require a lot of working out.

25,615. What means have you of arriving at a conclusion as to cause of death in the case of the people who die in Bombay? Will you put in all the information in answer to that question? As far as I have understood it is from inquiries by Hospital Assistants at the graveyards?—You leave out the cases the district officer knows before.

25,616. That is a small percentage?—It is a large percentage.

25,617. I want to know what means there are of determining the causes of death in Bombay?—(Witness subsequently supplied the following information):—From an examination of my weekly records for the week ending 4th March 1899, I find there were 2,307 deaths reported from the cemeteries and burning grounds. Of those 2,155 were traced in the city, 1,077 were found to be due to plague, 513 occurred in hospital, and a considerable proportion of the remainder were seen by the Sectional Medical Officers either before or after death. I am unable to give the exact proportion, because being satisfied that my officers do not put down deaths as due to plague without proper verification, and finding rather that the tendency is to accept the statements of relations that death is due to some ordinary cause, I have not exacted from them any systematic account of the grounds on which they put down a death as due to plague. Of the remaining 1,078 deaths that were traced—

287 were seen by the Sectional Medical Officers before or after deaths.
90 were certified by qualified practical practitioners.
1 was certified by a medical practitioner (unqualified).
38 were seen before death by members of the volunteer Plague Committees.
44 died in the public hospitals.
2 died in the Lunatic Asylum.
1 in Military Lines.

463

giving a total of 463 where there was fairly satisfactory evidence that death was not due to plague. In the remaining 615 cases the Sectional Medical Officers visited the houses where deaths occurred, and made inquiries to the best of their ability from the friends, residents, and neighbours. In 290 cases they satisfied themselves that death was not due to plague. In the remaining 325 cases the results of their inquiries were unsatisfactory, and they were put down as suspicious.

To sum up, out of 2,307 deaths, 1,077 were undoubtedly due to plague. In 325 cases the results of their inquiries lead the Sectional Medical Officers to put the deaths down as suspicious. In regard to 463 there was fairly satisfactory evidence that they were *not* due to plague. In 290 cases the Sectional Medical Officers satisfied themselves by inquiries that death was *not* due to plague. In 152 cases it was impossible to make inquiries owing to failure to trace the houses where the deaths occurred.

The average death rate for the corresponding week in years before the outbreak of the epidemic was 543. In the week under examination, putting on one side the 1,402 cases of plague and suspicious, there were 905 deaths in regard to which no action was taken for plague. The difference (362) between 543 and 905 should, however, be reduced by 103 deaths due to an epidemic of measles, in order to arrive at the approximate number of plague deaths which altogether evaded detection. For the week under examination I estimate this number at 259.

25,618. Could you not receive more complete information than you do at present by a system of corpse inspection?—Undoubtedly.

25,619. Do you think corpse inspection would arouse much opposition?—Undoubtedly it would.

25,620. Do you think it would arouse less opposition if conducted at the graveyards, or burning ghauts, than if conducted at houses?—I think it might be conceivable, by very very slow processes, to arrive at a certain amount of compulsion that they should be examined in the houses, but it would be a very slow process, and probably take a couple of years to work up to.

25,621. If you find out that you know very little about the causes of death in the large majority of cases, then you feel inclined to think that a system of corpse inspection should be gradually introduced, you think it would be wise, and that it would be an advantage to introduce it?—Yes.

25,622. (*Mr. Hewett.*) Is a certificate required from a duly qualified qualified medical officer before anybody can be sent to the Plague Hospital?—Yes, but it is not insisted on in every case; if there is no doubt, and the people do not object.

25,623. Have you any knowledge of the number of cases sent to the Plague Hospital under certificates, who have turned out to be not suffering from plague?—I have no idea whatever.

25,624. Is it a considerable proportion?—The doctors in charge of hospitals are inclined to make rather a fuss about such cases. One or two cases have come to my knowledge, but not a large number. The tendency is rather on the other hand to send cases for observation, which are really plague, I think.

25,625. Do you find any tendency among the relatives and friends of patients to send them to hospital?—There are a certain number who go every week voluntarily. It is a very fair proportion of those who do go to hospital now.

25,626. Have you any facts to show the tendency of a second case to occur in a house where a case has already occurred?—I had some statistics collected, but I really do not think they are very valuable, but I have got them here if you wish to see them. I have not worked them out myself, but that is the belief I always had till I got these statistics, that there was a tendency for cases to recur in a house. These statistics seem to show that the number of houses where single cases occurred is rather larger than I anticipated, but whether that is due to disinfection or not, I do not know. There are the facts.

25,627. Have you found a tendency for a second case to occur in those instances in which you have left moribund patients in their houses?—No, I have not found that particularly, but all these things are questions of close observation, which we have not got the means of carrying out in Bombay—we have not got the establishment, nor the knowledge of the cases that occur.

25,628. Have you permitted people who are not moribund to be treated in their own houses here?—No, except in thoses cases that I spoke of.

25,629. Are you still taking all the contacts to contact camps?—We have not got what you would call a contact camp, I mean the restrictions are almost entirely abolished. All we can say is that, "you must "bring your cooking pots to camp, and you must live "there." They can go to their work, but they are expected to sleep there; they do not go to their own houses.

25,630. Do you think that you know little about the cause of death in the great majority of cases of death?—I do not think so. Of course we do not know much about the ordinary causes of death. We do not bother very much, as long as we are satisfied that it is not plague. We take more or less what the cemetery clerks put it down as, if there is nothing suspicious.

To reduce it to the minimum, I should say that there are 300 cases a week which we make mistakes about, that are probably due to plague, and which we have not treated as suspicious.

25,631. Your meaning, then, is that by the facts ascertained by district officers, and by reports in hospital, supplemented by the subsidiary inquiries which are sent to the Health Department, you manage to ascertain the cause of death in all but about 300 cases a week?—That is about what I worked it out last week.

25,632. (*The President.*) Do you find it now more easy to induce people to go to hospital than in former epidemics?—My experience of former epidemics was not very great. Of course there was a great deal more force displayed always in the time of the first outbreaks, and I do not think the people cared to face the possibility of a struggle with the authorities then. As a matter of fact, now, there has been no case in which, to my knowledge, a man has absolutely resisted being taken to hospital. A case did occur to me one day, but that was eventually got over. He wanted to leave the room, but the doctor stood in the way: that was all.

25,633. In regard to moribund cases, which have been left at home for treatment, have you any knowledge whether such cases have or have not been the means of communicating plague?—I have no figures that I could put before you. I do not think it is possible to form any real opinion about it in Bombay, because, as I say, our men are all working hard, and they have not time to carefully study each case, and, also, there are a certain number of cases which escape observation; so that any observation would be very incomplete; but so far as I have heard from the district officers here, I have not heard it stated that moribund cases left at home have had a tendency to spread plague. Cases occur afterwards, but then they have in many houses two or more cases, so that that again would not attract much attention; they could not say that it was because any case was left in the house that it caused the spread of plague. A district officer having a badly infected locality told me that he thought it was entirely due to one or two cases being left in the street; but there, again, it is an unsound inference, it seems to me; there were a number of cases, and two cases had happened to be left there.

25,634. You have not followed up the question sufficiently in order to answer it definitely?—No, it is a very large question indeed.

25,635. I understand, therefore, that you do treat certain cases in their own houses?—We leave moribund cases at home.

25,636. Only the moribund?—I think I explained that—that there were a certain percentage of cases, mostly rich people and influential people, who obtain certificates to the effect that the patient is in an exceedingly precarious condition, and that the removal will cause a great risk of death; and if the opposition is very great, we give it up. One does not like to enforce the removal, and to face that risk.

25,637. (*Prof. Wright.*) You said in answer to Mr. Hewett that you knew the cause of death in all but 300 cases a week?—Yes, I worked it out last week.

25,638. You mean that there were 300 cases of plague which you do not recognise as plague?—That is the conclusion I came to. There are a certain number of cases that are treated as suspicious. There is no record, but they disinfected in those cases. These suspicious cases are excluded from the 300.

25,639. When you recognise a case as plague you disinfect the house, do you not?—Not the whole house.

25,640. How much, when it is a chawl?—The room itself, and generally the two adjoining rooms.

25,641. How many houses would be disinfected in a day when, for instance, the mortality is 391? That would involve a disinfection of over 300 houses?—Probably.

25,642. Have you the means for disinfecting 300 houses in a day? How many gangs have you got?—I cannot tell you how many gangs, but there are about six or seven men in a gang, and there are about 600 men actually employed.

25,643. That would be 100 gangs?—About 100 gangs.

25,644. Have you got plant for 100 gangs?—The plant is not very much.

25,645. I mean, such as it is; you would want a bucket and a pump, and you would also want an Inspector?—We have not got an Inspector to every gang. We have got a muccadum, who is the head coolie. The Inspector goes round to three or four or five gangs.

25,646. Is the muccadum a responsible man that you can trust?—He is merely a head coolie; he is held responsible by the Inspector.

25,647. All I want to arrive at is this: when you have 300 houses to disinfect in a day, have you got the men and the staff to do it in a way that you would consider satisfactory?—Yes, it is done.

25,648. Are you satisfied whether it is done properly?—It is a question for you to decide whether it is satisfactory.

25,649. I want to know whether you are satisfied with it?—I am satisfied with it to this extent, that if you want to make it perfect you must go bankrupt at once.

25,650. Are we to write down in our minds that it is an effective or ineffective method of disinfection, or is it possible that a large number of the disinfections are not properly done?—I do not think it is really satisfactory. Every house ought to be disinfected by a doctor, I understand.

25,651. With the staff and the plant that you have got, how many houses do you think you could manage to do in a day in a way that would enable you satisfactorily to make this a basis for a further inference as to the way in which plague spreads?—I have never attempted to draw a plan of that. If the district officers tell me that they find it difficult, they are at once given more coolies and supervising staff. I have never attempted to form any estimate of the exact number of coolies required for so many cases. If they find their men are overworked, the work is done in the same way, only it means that the men go on working longer hours, and they go to houses a longer time after the infection has occurred.

25,652. You do not think you can infer, with a death-rate of 391 in a day, that 300 houses are cleared from infection by your disinfecting operations on that day?—I think, from the analysis of my disinfections, it occasionally does occur that the work is not properly done.

25,653. (*Dr. Ruffer.*) What do you mean by occasionally; that is rather an elastic term? Do you mean 10 a day, or 20 a day? "Occasionally," in my mind, means 1 in 100. I want to know what it means to you?—I should say 3 or 4 in 100 is my idea of it, but it is impossible for anyone to say.

25,654. I want to know about the cemeteries. Is it true that the Assistant Surgeon at the cemetery is on no account to examine bodies there?—He has orders not to.

25,655. Under any conditions?—Yes.

25,656. I went to a cemetery the other day, and a child was brought in, and the relatives said it had suffered from asthma. I believe the child's certificate in the registration in the cemetery afterwards was entered as "General Debility"?—Was not it the other way round?

25,657. It would come to the same thing. It was given to me as asthma?—I saw the certificate of the Plague Authority, that it was "General Debility," which I believe came in afterwards, that is to say, after the cemetery clerk had made his diagnosis.

25,658. The relatives told me the child had asthma. How did the Plague Authority come to the conclusion that it was general debility?—I did not ask him in that particular case, but he had probably seen the child suffering for months previously.

25,659. He had not seen the child at all. The friends told me that it had not been seen by a medical man at all?—This is a Plague Authority, who is not necessarily a medical man.

25,660. The Plague Authority wrote it down, and it was entered in the register as general debility, but the friends said it suffered from asthma. I want to know how the plague officer arrived at that conclusion?—It depends in each case; generally it is that he has seen the case suffering. You say the friends of the child told you that he had not?

Mr. J. H. Du Boulay, I.C.S.

17 Mar. 1899.

25,661. That is my impression, but we will ask Dr. Weir?—You cannot trust what the people say. You and Dr. Weir were there, and they were probably frightened, and perhaps thought that you were going to do something; so they might have given you a different story from what was on the certificate. I have to add, in regard to the question of compulsory removal to hospital, that we do not attempt to deal with the Health Department sweepers. They are difficult to manage, and the disastrous possibilities of a strike among them compel us to leave them alone as a matter of policy. They are isolated, so far as possible, in their own chawls, and dealt with entirely by the Health Department itself.

(Witness withdrew.)

Lieut.-Col. T. S. Weir, I.M.S.

Lieut.-Col. T. S. WEIR, I.M.S., recalled and further examined.

25,662. (*The President.*) When you were before us previously we asked you for certain statistics with which you are now in a position to supply us?—Yes.

25,663. You were asked about a case of plague which was communicated by a rat-bite and about cases of importation by sea?—I have not been able to get the information as yet.

25,664. Then there was a question raised as to the period of incubation?—That information is not ready yet. I have sent circulars round to all our medical men.

25,665. You were asked if you could supply us with the number of cases of plague in each ward or district in Bombay since the origin of plague?—I have a return showing the mortality since 1896, as follows:—

STATEMENT showing the NUMBER of DEATHS from BUBONIC PLAGUE from 1st September 1896 to 16th March 1899.

Wards, &c.	Sections.	From 1st Sept. to 31st Jan. 1896.	1897.	1898.	From 1st Jan. 1899 up to 16th Mar.

	Worli	25,493	11,390,400	446·80	2353·38	10·83

25,668. How far do you think the figures in that table are correct?—The table must be interpreted with a number of reservations. For instance, there is the section of Dongri. Dongri is the section immediately to the north of Mandvi and includes Dongri Hill, which is inhabited on one side, and the quarry-holes on the east and also open land. Then there is the migration of population backwards and forwards.

25,669. You mean that a large portion of this section has no houses?—Yes; so that really the populated portion of Dongri is much more thickly populated than would appear by the table. It is the same with regard to Fort North and Fort South. The area for each person is less than would appear from the table. Then, of coure, there is a great migration of population backwards and forwards from Bombay. They go from Bombay to the country for work, and during plague years there is a great migration of population from the town proper into the suburbs, and also migration from the suburbs into the town proper.

25,670. At what period of the year were these figures collected?—They are taken from the census, from an enumeration which was made in February.

25,671. What was the migration then?—Very large numbers of people came into Bombay for work.

25,672. And they remained there from February till when?—Till the beginning of the monsoon, in June.

25,673. Therefore the numbers would only apply to half of the year?—Practically. That is one of the conditions which you have to remember in interpreting these figures.

25,674. (*Dr. Ruffer.*) With regard to the mortality as compared to the area you stated, I think, that it was smaller in certain wards?—The density of population in Bombay varies from seven square yards to each person, to over 800 square yards in the extreme suburbs.

25,675. Was the plague worse in the more densely populated quarters?—No. It is a most extraordinary fact that the mortality in the buildings in the most densely populated portions of the town has absolutely been less than in small villages in the suburbs, according to our statistics.

25,676. Are their houses as much overcrowded in the small villages as in the town?—No; they are not so overcrowded.

25,677. How do you know that?—From the census figures which show a decreasing population from the city outwards, in dwellings; 37 per cent. of the population live over 3½ per cent. of the surface area. You have, in proportion to your house area, a larger number of rooms than you have in the suburbs. In the next place you have people living in the town whose necessities compel them to overcrowd each other more. And you have a population in house-passages and in the streets.

25,678. But that is only an impression?—No; that is undoubtedly so. There are no houses in the suburbs so overcrowded as in the city.

25,679. Have you a census of the villages showing that as compared to their area they are more overcrowded than the smaller part of the town?—We have statistics which could, of course, be found, showing the number of persons per houses in villages in which cholera or plague has occurred.

25,680. Then, according to your evidence, overcrowding is not the chief factor in producing plague?—No, that is not my point; I believe it is a very important factor. But there is this fact in our statistics that the plague mortality was highest in the suburbs.

25,681. Do you think that is accurate enough to base a conclusion upon?—The statistics are absolutely correct; there is no doubt whatever as to that, and there are explanations.

25,682. What is your explanation?—Let us take, for instance, the mortality in the House of Correction. The mortality there according to the population was really higher than occurred in some of the most crowded chawls of Bombay. It is very difficult to give an explanation of that, but there is the fact. The only explanation I can give is that it is a place for prisoners, and in order to keep prisoners you must build a wall, and the wall round the prison and the walls inside it may possibly obstruct the perflation of air and give less perflation of air than exists in the most crowded chawls of the town. That is the only explanation I can give, and it is not a very satisfactory one.

25,683. (*The President.*) How long does a prisoner remain in the House of Correction?—It is a short term prison.

25,684. Where do they usually come from?—From Bombay itself.

25,685. From the better or worse localities?—From the worse localities.

25,686. Therefore there is a constant stream passing through the House of Correction of persons from the worst localities?—Yes.

25,687. Are not these prisoners likely to have come in contact with plague?—One would think so, but we have the fact that, except for the small outbreak that occurred in the House of Correction, the place has suffered very little from plague. What occurs to me is this, that if the continual stream of people from the poorer classes into the House of Correction was the cause of the outbreak in 1897, it would be a constant cause in operation since.

25,688. You mean that there was a local outbreak, and not that the House of Correction was a place where plague had been especially prevalent?—That is so.

25,689. (*Dr. Ruffer.*) Has there been any plague in the Jail since 1897?—I am not quite sure till I inquire: there have been, I think, three cases in 1898 and none in 1899.

25,690. (*The President.*) What kind of houses are these suburban houses where plague has been prevalent?—They are the old-fashioned houses which have a number of inner rooms, not communicating directly with the external air, and very ill-ventilated.

25,691. In which of these rooms do the people live and sleep generally?—In the inner rooms.

25,692. Where there is very bad ventilation and darkness?—Yes, and the ground is damp.

25,693. Further than that, is it at all probable that when plague is bad in the town there might be an exodus to these suburban houses in any large extent?—Yes, there is an exodus to them, but against that there is also an exodus from the suburbs into the town. You have at one period a migration into the suburbs and, at another, a migration from the suburbs.

25,694. During plague?—Yes.

25,695. When do they come from the suburbs into the town?—When the disease becomes prevalent in the suburbs.

25,696. And already it has become prevalent?—Yes.

25,697. Before the time it became prevalent there might have been an exodus from the city to the suburbs?—Yes.

25,698. And, therefore, a condition of special overcrowding at the time when in the suburbs plague was most prevalent?—Overcrowding in this way, that you

Lieut.-Col. T. S. Weir, I.M.S.

17 Mar. 1899.

have a certain increase of the house population and also a larger number of people living on the open ground in camps.

25,699. But, above all, although these are suburban dwellings, they are not free from the defects which are commonly found in the centre of a city with regard to lighting and ventilation of the inhabited parts of the houses?—That is so.

25,700. (*Mr. Hewett.*) Have certain portions of the streets in Bombay in recent years been rebuilt?—Yes, they have been widened.

25,701. Has any alteration been made in the houses in those streets?—A good many alterations have been made in the houses.

25,702. In the particular streets to which I am referring?—Yes, to improve light and ventilation.

25,703. Can you specify a particular street in which it has been done?—Yes, Girgaum Road.

25,704. Any other?—Yes. Abd-ul-Rahman Street.

25,705. Has anything been done in Arthur Road?—No; that is part of a new street.

25,706. It has not been widened, but it is a comparatively new street?—Yes. The portion between Chinch Pooghly Station and Parel Road has been built upon within the last ten years.

25,707. And Cotton Road?—Cotton Road is one of the new streets.

25,708. In these particular places are the lighting and ventilation and the perflation of air through the houses better than in other parts of Bombay?—Undoubtedly. Take, for instance, a new road, a road constructed in 1885, Ripon Road, and also Morland Road, immediately east of the Byculla Club. They are new streets with new houses.

25,709. Is the lighting and ventilation better there?—Undoubtedly, very much better. There are a number of chawls in these streets very fairly ventilated indeed.

25,710. Have you any statistics to show the ratio of attacks from plague and deaths from plague in these new streets, compared to the ratio of attacks and deaths in the other portions of the town?—We have the statistics, but we could not give the ratio.

25,711. Do you know the population of these particular streets?—Not exactly.

25,712. Not approximately?—With the continual changing of the population of Bombay and the construction of new buildings, it is extremely difficult to get it even approximately, and it is most uncertain. What we can do is to give the actual number of cases and attacks and the population of the last census. To do more it would be absolutely necessary to take a census.

25,713. Was plague bad or not in these particular streets to which you have just referred?—Plague undoubtedly was bad in one street, and in chawls off or close behind another—Morland Road. I am convinced that it would have been very much worse if the streets and houses had not been as well-ventilated as they are.

25,714. Was plague worse in Morland Road than it was in the badly overcrowded portions of the town?—No; I would not say it was worse, but it was very bad. The chawls were as much affected as in the most densely populated portions of the city.

25,715. I want to know whether the attacks and mortality from plague in Morland Road were as bad or worse than in the worst portions of Bombay?—I can only answer in a very general way. The figures are here. I think they were just as bad, although Morland Road has hundreds of yards of open ground on one side.

25,716. What is the average area per person in the suburbs?—It varies. You have from an average of 832·42 square yards for each person in Sion to 7·22 square yards to each inhabitant in Khara-Talao section.

25,717. You say that during the course of a plague epidemic there is an exodus from Bombay to the suburbs, and also at times a corresponding exodus from the suburbs to Bombay?—Yes, a migration backwards and forwards.

25,718. Does the population of the suburbs become as congested or more congested than the population of the town at any period in the epidemic?—Never; it never becomes so congested.

25,719. Can you give us the total mortality per month from the 23rd September 1896 to the end of February 1899?—Yes, it is as follows:—

TOTAL MORTALITY during the following YEARS.

1896.				1897.											
September.	October.	November.	December.	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.
925	2,994	3,024	6,244	7,627	6,928	5,419	3,620	2,433	2,326	3,112	4,076	3,616	3,389	2,984	3,736

(*continued*).

1898.												1899.		
January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	January.	February.	March 1st to 16th.
6,802	8,283	9,303	5,185	3,021	2,106	2,435	3,264	3,618	3,664	2,646	3,311	5,796	7,576	5,426

25,720. Will you give us the normal mortality for the same period?—I will prepare that table. (The following figures were subsquently supplied by the witness):—

STATEMENT showing MONTHLY AVERAGE MORTALITY for 5 years from 1891 to 1895.

January.	February.	March.	April.	May.	June.	July.	August.	September	October.	November	December.
2,150	2,132	2,322	2,480	2,480	2,078	2,246	2,423	2,188	2,099	1,938	2,093

25,721. Will you give us the total recorded plague mortality for that period?—Yes, it is as follows:—

STATEMENT showing the NUMBER of PLAGUE DEATHS in the following years.

1896.				1897.											
September.	October.	November.	December.	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.
79	313	273	1,271	1,857	3,083	2,266	1,316	328	99	42	70	168	178	255	644

(*continued*).

1898.												1899.		
January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	January.	February.	March 1st to 16th.
2,934	4,498	4,973	2,171	524	150	263	543	731	728	217	470	1,591	3,040	2,452

25,722. What is the average normal mortality?—Our average mortality is about 28 per thousand.

25,723. Can you tell us to what extent the Health Department has been added to recently?—Yes; I have prepared a table showing that. It is as follows:—

RETURN of STAFF employed in the HEALTH DEPARTMENT up to the end of SEPTEMBER 1896, and that employed up to the end of FEBRUARY 1899.

—	Divisional Health Officers.	Deputy Health Officers.	Inspectors.	European Sub-Inspectors.	Native Sub-Inspectors.	Ward Clerks.	Muccadums.	Patels.	Cart Drivers.	Bigarees Men and Women.	Halalkhores.				Gully Flushing Establishment.					Special Medical Officer on Plague Duty.	Hospital Assistants.	Rat Killers.	Report Hospital Bearers.
											Sub-Inspectors.	Cart Drivers.	Trip-Markers.	Muccadums.	Halalkhores Men and Women.	Engine Drivers.	Firemen.	Sub-Inspectors.	Muccadums.	Bigarees Men and Women.				
Permanent establishment up to 30th September 1896.	—	—	7	7	44	7	57	22	639	1,950	2	127	—	47	1,646	—	—	—	—	—	—	—	—	—
Permanent establishment up to 28th February 1899.	4	7	8*	5	36	7	44	29	640	1,908	2	139	—	55	1,865	7	7	6	7	154	—	—	—	—
Extra establishment on account of plague up to 28th February 1899.	—	—	—	18	53	8	68	—	—	555	—	—	13	49	152	—	—	—	—	—	31	5	8	6

* One acts as Inspector.

The Tardeo Flats, Night Branch, and Veterinary Establishments are not shown in this statement.

25,724. In ordinary circumstances have you any Assistant Health Officers here in Bombay?—Previously to 1896 I had no medical Assistant Health Officers.

25,725. Under ordinary circumstances the Health Officer would have to do the whole work himself?—Yes, except during epidemics, when a medical staff was engaged.

25,726. Can he do the work at ordinary times, and so protect the town against epidemics?—I do not think he can now without a large medical staff.

25,727. Your establishment has been considerably increased?—Very much increased.

25,728. How many Medical Officers have you under you in the Health Department?—Eleven for Health Department duties.

25,729. Is that more than you want?—No. The total number of Medical Officers absolutely now employed on plague duty and Health Department duty is 42.

25,730. How many of those 42 are Europeans?—Five. There are a number of Eurasians. There are seven medical men who are Eurasians, and they are all qualified.

25,731. Can you give the total number of persons who have been sent to public and private hospitals since the beginning of the epidemic, supposed to be suffering from plague?—Yes, as follows:—

STATEMENT showing the NUMBER of PLAGUE PATIENTS admitted into all PLAGUE HOSPITALS, PUBLIC and PRIVATE, from March 1897 to March 1899.

—	No. of Plague Patients.
From March to June 1897:—	
Public hospitals	1,531
Private hospitals	1,244
From July 1897 to April 1898:—	
Public hospitals	3,957
Private hospitals	4,157
From October 1898 to March 1899:—	
Public and private	5,818
	16,707
	184
	16,891

Lieut.-Col. T. S. Weir, I.M.S.

17 Mar. 1899.

25,732. Can you give us any figures for any particular hospital or hospitals to show what proportion of the persons supposed to be suffering from plague when they were sent to hospital were afterwards found not to be suffering from plague?—Yes. About 66 of the patients admitted in the Mahratta Hospital turned out last year to be cases of simple or relapsing fever. About 56 of the patients turned out to be suffering from diarrhœa, relapsing fever, or some other cause, from January 1899 up to 14th March 1899. About 10 per cent. of the patients sent to the Arthur Road Hospital do not suffer from plague but from some other diseases. From the 1st of August 1898 to the 15th of March 1899, 2,021 of the patients admitted in the Modikhana Hospital were not suffering from plague.

25,733. Were those people who were subsequently found not to be suffering from plague sent to the Arthur Road Hospital, by Medical Officers or by other people?—That I could not say, they may or they may not have been.

25,734. Can you give us any information as to the proportion of persons sent (1) to public hospitals, and (2) to private hospitals, who died within 24 hours of admission?—Yes. At Arthur Road Hospital about 38 per cent. died within 24 hours of admission.

25,735. You are probably familiar with Section 449 of the Bombay Act of 1888 regarding the registration of deaths, which places an obligation on certain persons to report death at or about the time the corpse of the person is disposed of?—Yes.

25,736. Have any subsidiary rules been issued on this matter?—No.

25,737. Do people habitually report deaths, and their cause?—At the cemeteries.

25,738. That is how that Section is interpreted?—Yes.

25,739. The report you get is the report from the cemetery?—Yes; there may be a certificate from a medical man.

25,740. For the purposes of this rule, if it is reported at the cemetery, that is taken to be a compliance with the law?—Yes. I have in my last Annual Report on the Health of Bombay, 1897, discussed the measures that should be taken for the improvement of the system of registration of deaths. I have described the steps to be taken towards correct registration. The importance of improvement is very great. The law must be altered, medical men must be registered, and medical relief given to the poor, who must be treated while living or examined after death, the latter a very serious alternative in this city not lightly to be recommended. The same object can be secured in a different way by treating every death as a death due to an infectious disorder and disinfecting the bedding.

25,741. (*Mr. Cumine.*) With regard to the drainage of Bombay, in what parts of the city do drains exist?—Roughly speaking up to Clark Road, a line from east to west through Clark Road. More than a quarter of the island is without drains.

25,742. On which side are there drains?—On the south side of Clark Road

25,743. Are the houses connected with those drains?—The houses are all connected, but only a certain proportion of the houses have house-connections on the new system.

25,744. Are the connections in working order?—Yes.

25,745. Did not Mr. Baldwin Latham, the famous expert, come to Bombay to advise the Municipality on drainage?—Yes.

25,746. Did they accept his advice?—The advice was accepted, but his proposals have not all been carried out yet.

25,747. On what system did he advise Bombay should be drained?—He practically approved of the present system except with regard to the outfall: he suggested another outfall

25,748. Is Kolaba drained, and the Fort?—Yes.

25,749. Chowpati?—Yes.

25,750. Malabar Hill?—No, Malabar Hill has open storm water drains.

25,751. Is the drainage of the rest of the town proceeding at present?—Yes; a great deal of work has been done since 1896.

25,752. Has it all been done on the same system, or has the Shone system been introduced anywhere?—It is being introduced into certain districts in which the levels will not permit of gravitation into the general system.

25,753. Now, with regard to rain-water?—That is separated from the sewage. The removal of rain-water is arranged for in a separate system of drains.

25,754. Have the houses got closets?—There are only a few hundred closets in Bombay. In the drained districts the solid matter is received in baskets or in pans at the bottom of the privies, and removed by Halalkhores, and the fluid portion flows into the drainage system. The Halalkhores remove the solid matter in baskets to depôts. There are a number of depôts which are the points on which the Halalkhores work. Each depôt is an unit of organisation. All the depôts in the drained districts are connected with the drainage system. The night-soil in the baskets is emptied into hoppers in the depôts and discharged through the sewage system.

25,755. And eventually the sewage goes to the sea?—Yes.

25,756. How does it reach the sea? Is it pumped up? Yes.

25,757. (*The President.*) Do you mean the solids as well as the liquids?—Yes.

25,758. The whole?—Yes. The difference in the drained districts is simply this, that the night-soil, instead of flowing direct from the water-closet to the sewer, is carried in baskets from the privy to the depôt, and discharged into the sewers.

25,759. I suppose in these closets there is a tube connected with the drain for liquid matters?—Yes. A connection.

25,760. There is a percolation from the baskets?—Yes; the bottom of the basket is porous. In the houses which have been connected on the new system the liquids flow into a pipe, and the pipes are connected with the street sewers. The districts where house connections on the new system have not been carried out, the liquid matter flows from an open gati into the street sewers. In districts which have not drains the solid matter is removed to depôts, and the liquid matter is received in cesspools.

25,761. (*Mr. Cumine.*) What is the old system and what is the new system?—The old system is a system of open galis or drains; the new system is a system of pipe connections, with intermediate portions of properly constructed open drains.

25,762. Is the new system being introduced universally now in supersession of the old system?—Yes.

25,763. What is to prevent the solid matter from going into the drains direct?—The receptacles.

25,764. To the north of Clark Road I understand there are no drains?—Practically no drains.

25,765. What is the system there of removing the night soil?—The same as in the town. It is removed to the depôts, and from there it is carried back to the nearest district where there is a sewer, and emptied in the sewer.

25,766. And the liquid matter?—That is received in cesspools, and a small portion of the cesspool matter is also removed to the depôts and discharged into the sewer. The remainder either soaks into the ground, or is spread over the ground, or is used for irrigating the ground.

25,767. Have you noticed that the existence or the non-existence of drains has any marked effect upon the health of the people?—I have no doubt whatever that the existence of the drains has a most favourable effect. Considering the density of our population and the miserable economic conditions under which they live, I think the relative low mortality is due in a great measure to the drainage that we have. The mortality from plague has been made lower in Bombay and Madras than in other cities in India.

25,768. How is the drainage system better for the health of the people than the system of removing by hand which prevails to the north of Clark Road?—The system which prevails to the north of Clark Road is only possible in very sparsely populated districts. For that system you have ground for a cesspool, and you must also have ground on to which a portion of the matter can flow.

25,769. If the drainage system has a good effect upon the health of the people, I presume the people who live

Lieut.-Col. T. S. Weir, I.M.S.

17 Mar. 1898.

n the north of Clark Road have not such good ealth as the people who live on the south of it?—That is not so always in all districts, except since plague came.

25,770. On what do you base your opinion that the rains are good for the people?—On statistics, and ecause the filth is removed from the neighbourhood f the dwellings. Where there is no system of drainage he filth accumulates and percolates into the ground.

25,771. That is a theoretical reason?—Absolutely so. have no doubt as to its truth.

25,772. Is it within your knowledge that the health f the people in any portion of Bombay south of Clark Road has improved since the drainage system has been introduced?—Yes. In certain districts the health has improved undoubtedly.

25,773. Which are they?—The Market, for instance, nd the Fort, Khetendi, and others. The districts hat have been drained have shown a progressive mprovement in health.

25,774. Why are solids in the drained portion of Bombay removed by hand in this way? Why are they ot allowed to pass straight into the sewer?—On ccount of the difficulty of getting the people to use ater closets, and the danger of having water closets.

25,775. What is the danger?—The danger is that hey would be improperly used and become obstructed.

25,776. (*Prof. Wright.*) Are the present pipes obtructed?—Obstructions do occur, but they are nfrequent.

25,777. (*Mr. Cumine.*) Is the basket movable?—Yes.

25,778. Is it found that the people remove baskets nd introduce something into the pipe which obstructs t?—Into the basket, or it may be over the basket, ieces of cloth are thrown, also stones, pieces of stick, and pieces of earth. A certain proportion of the population use balls of earth after ablution. The women throw down the privy the cloths which they use in a certain portion of their life, and if those cloths happen to fall into the gali trap or pipe they may cause an obstruction.

25,779. (*Prof. Wright.*) Can you give us the comparative number of attacks in segregation camps as compared to those among the rest of the population?—I have sent that in.

25,780. You have not given us the number of people in the segregation camps, and therefore we are not able to work out the percentage of attacks?—I am afraid it would be rather difficult to get the number; there is no record for some of the camps in 1898.

25,781. Will you see whether you are able to obtain that information?—Yes. For some it can be given and in some it cannot. (Witness supplied certain figures, but they were incomplete, and he was unable to supply such figures as were required.)

25,782. (*The President.*) I suppose your drainage system in Bombay is not yet completed?—That is so.

25,783. Therefore you are not in a position to accurately estimate the advantage which you will derive from a complete system?—We are not yet able to fully edstimate the advantages of the system.

25,784. With regard to Morland Road, are there any special conditions and circumstances in the houses there which are favourable to the prevalence of plague?—Yes; there are a very large number of poor people and outcasts living in very crowded rooms, and rooms which they crowd with screens and purdas.

25,785. Were the conditions in Morland Bay exactly the same as in the most crowded buildings in the towns?—Yes; they are exactly the same inside the rooms only, but not outside.

(Witness withdrew.)

Lieut. H. V. Firth, I.S.C., called and examined.

Lieut. H. V. Firth, I.S.C.

25,786. (*Mr. Cumine.*) Your first experience of plague measures was, I think, as officer in charge of the railway detention camp at Bhusawal, in the early part of last year?—Yes.

25,787. In what month did you come to Bombay?—In June.

25,788. What ward were you placed in charge of?—E Ward East.

25,789. What parts of the town did that comprise?—Mazagaon, Tarwadi, and Byculla.

25,790. With regard to disinfectants, have you any reason to disbelieve in the efficacy of a single application of perchloride of mercury?—Yes; I did not see it was of much use. You empty the chawls, disinfect once, and put the people back again after a fortnight or a month, or any length of time, and as soon as you put them back again they get plague just as badly.

25,791. Therefore, what did you do?—I disinfected the room in which a plague case had occurred every day for a week with perchloride.

25,792. Having done this, did you find that the people on re-admission again got plague?—Not in the rooms that had been disinfected for a week, but in the other rooms. I believe in disinfection once if you get it in the early stages. For instance, if you find dead rats, and disinfect at once, that will stop plague; but if plague once gets a hold on a chawl, once disinfection is no good at all.

25,793. When you came to your ward in June 1898, was it badly infected?—No, there were only cases here and there.

25,794. As it gradually became infected to what did you attribute the infection?—At first, people with plague came from other wards, nine-tenths of the cases. When the plague staff got energetic in other wards they came into my section. Also, I think rats spread the disease. I do not know whether the rats got it in the houses or brought it in, but when we were taking the tiles off, we found rats everywhere, all over Mazagaon and Byculla.

25,795. Did the death of the rats appear to precede plague in human beings?—Yes.

25,796. With regard to the removal of patients to hospital, I think that soon after your arrival in Bombay you allowed at first a small number, and latterly a considerable number, of patients to remain in their rooms?—Yes.

25,797. Did you always leave them in their rooms?—No; sometimes we left them in their rooms and sometimes we put them in huts in the compound.

25,798. When you left the patients in the rooms, what did you aim at specially in order to prevent the contacts from getting plague from them?—We used to mop the floors and walls with a strong solution of perchloride, and then we used lime on the floors to keep them dry. We used to take the patient into the passage while we did this. We did not use the perchloride every day, but we used lime every day, and we gave the patients pans for spitting into and for droppings.

25,799. Did you allow the patients to sleep upon the floor?—No; we gave them a cot and blankets, or whatever they wanted. We used to burn all the infected clothes first of all, and then give them saris or dhotis and whatever was necessary.

25,800. Did you leave the family of the patient?—Yes.

25,801. In cases where the patient died, what did you do after the death?—We disinfected the rooms and sent the contacts to a contact camp. If the patient did not die, we left the contacts there and disinfected the room, and allowed them to go on living there as if nothing had happened.

25,802. In, approximately, how many cases did you leave the patient in the room or in a hut in the compound?—I have a record of about 50, but I think it must be over 60.

25,803. So far as you can see, did the contacts catch the plague?—Not so far as I could see. If you did not disinfect the room the contacts would get plague, not from each other, but from the poison in the room.

25,804. Where you did disinfect the room?—Not a single contact took plague.

25,805. After a time had you to give up this system of leaving patients in their rooms and send them to

Lieut. H. V. Firth, I.S.C.

17 Mar. 1899.

hospital?—Yes; they were all sent to hospital at the beginning of December, I think.

25,806. Under what system was there was most concealment?—When we sent them to hospital. The more you worry them the more they conceal cases.

25,807. Have you lately reverted to the system of leaving the patients in their houses?—Yes, without disinfection.

25,808. How long is it since you reverted to this system?—I suppose about three weeks or a month.

25,809. You do not disinfect now?—No.

25,810. What is the reason of that?—Because the disease is of such a virulent type. It is no good doing so. They are generally dead by the next day.

25,811. Is the type a little milder now?—Yes, during the last week it has become so. Some patients have lived for three or four days.

25,812. Do you now, in any cases, remove people to the hospital against their will?—At present, we only send those who are willing to go, but we try to persuade them all to go.

25,813. Do you find a certain number of people are willing to go?—Yes, some are willing to go. I find when I go on my rounds that many have gone to hospital. On the first day, when the patient is not delirious, they will not send him to hospital, but on the second or third day they want him to go. So long as the patients have only simple fever, they like to treat the case as such.

25,814. Do you mean the patients themselves are willing to go to hospital?—No; I mean the friends desire to send them.

25,815. Under the system of no one being sent to hospital, unless his friends desire that he should go, do you have much concealment of cases?—I think I find nearly every case now, unless there is sudden death. I can only do it privately. If I leave one case in a chawl then they show me the other cases. But if I did not leave that case they would conceal all the other cases.

25,816. Do you consider that in order to have any measure of success in Bombay, the confidence of the people must be acquired?—Yes, you ought to work with the people. The more you gain their confidence the more they will help you, and the better all round. Only about 30 per cent. of cases are found now whereas 70 per cent. die without your discovering them. The less stringent you are the more cases you find, you would probably find 50 or 60 per cent.

25,817. Do you send any people to contact camps?—Yes, if we can find them, but they generally bolt.

25,818. Who are the people you send to contact camps?—When a patient dies of plague, the rest of the people in the room know you will go round and send them to contact camp, and by the time you get there they have bolted. They hate going to camp.

25,819. Why do they hate going to camp?—Contacts naturally hate going to camp; they like to go into another room. They are probably in the next room, if you could only find them; but it would take too much time to hunt up all the contacts. One is told that they have gone up country, when they are probably in the same chawl.

25,820. When you send them on to the Government camp, do you keep them there as long as they choose to stay?—No, only 10 days.

25,821. Do you think it is possible that the feature they dislike in going to a Government camp is the being turned out again after 10 days?—Yes.

25,822. Supposing you thought it wise to turn the people out of a chawl, how would you, yourself, think it best to treat them? Would you send them to a Government contact camp?—No; they do not like going to camp, because they are only allowed to stay there 10 days. If they have to go there they would like to stay there for a few months at least.

25,823. Do they like you to allow them to put up their own huts?—Yes, and that does not cost Government any money. I spent 300 rupees a day at one time, but now I do not spend anything on evicts.

25,824. Would the people think it a hardship to have to put up their own huts?—No.

25,825. Would they require the Government to provide materials for them?—No, because they do not pay rent if you give them a piece of land. They would be grateful for any assistance, but it is not absolutely necessary.

(Witness withdrew.)

(Adjourned till Monday, 20th March.)

At The Secretariat, Bombay.

SIXTY-EIGHTH DAY.

Monday, 20th March, 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT.
Prof. A. E. WRIGHT, M.D.
Mr. A. CUMINE.
Dr. M. A. RUFFER.

Mr. C. J. HALLIFAX (*Secretary*).

Major W. L. Reade, R.A.M.C.

20 Mar. 1899.

Major W. L. READE, R.A.M.C., recalled and further examined.

25,826. (*The President.*) We shall have to trouble you again for some further information with regard to Poona?—Certainly.

25,827. We wish to learn what has occurred in Poona with reference to the plague since we had the pleasure of seeing you there?—The disease has now been

stamped out. 26 cases of plague have been imported into Poona since 22nd of February. The type of plague imported is of extreme virulence. As an example of its intensity, I may instance the following:—A family of nine persons came from Bombay on 1st March 1899, and were under surveillance. One of the family died on the 4th March. On inspection by a medical officer the cause of death was pronounced as due to plague. Three other members were also suffering from plague, and the remaining members also showing signs of illness were admitted into the General Plague Hospital, when they all died, the last on the 10th instant. The virulence of the disease is also shown by the proportion of deaths to cases. To the 18th of March 290 cases have occurred, and of these 228 have already died; of the 26 imported cases of plague 24 have died. This importation of the disease is due to the large number of people who have come from Bombay, reaching Poona by rail and road. This influx from Bombay has been reported to me by the Plague Superintendent of the Station, who stated that two-thirds of the people from Bombay alighted at Poona. At Talegaon, a station 20 miles from Poona, where all Bombay trains stop, it has been reported to me by the Hospital Assistant on surveillance duty that a considerably larger number of people than usual have recently been alighting daily. The normal is about 200 a day, and latterly they have been arriving at the rate of 280 a day. There is little doubt that a large number of people come into Poona by road from this station in order to escape the restriction which they think will be imposed in Poona. On a house becoming infected, the inmates are sent to an observation camp where their clothes are disinfected and their names and thumb impressions are taken; these people are then allowed to carry on their ordinary avocations during the day and return at night to sleep. After four days' observation the names of the contacts are brought on the surveillance list of their Pet, where the remaining period of surveillance is undergone. Among the contacts 15 developed plague and nine died out of a total of 2,013 under observation, all these cases being within the incubation period of the disease. This is shown in the following statement:—

No.	Admitted Segregation.	Came from	Hospital.	Result.
1	14 February -	Budhwar, 348 -	18·2·99	Died.
2	23 „ -	Sadashiv, 649 -	—	Died in town 23·2·99

15	9 „ -	„ -	16·3·99	Alive.

15 contact cases of plague, of whom nine have died.

Under the present system of house census a larger number of contacts in proportion to the number of cases were kept under observation, that is to say, the average number observed to each case of plague is now seven, whereas in the last epidemic it was three. The ratio of attacks amongst the contacts is now one in 134; in the previous epidemic it was one in 98. In no instance have we been able to trace any infection due to a want in the disinfecting process, or to the short period which elapses between the time of removal and the return of the inmates. Only in two cases were patients allowed to remain for treatment in their own houses; the result was so disastrous that the trial was given up. I am of opinion that unless a private house can be placed under the conditions of a plague hospital the treatment of cases in such houses should not be attempted.

25,828. Can you give us details about the two cases you refer to?—I have the history of two cases which were treated in their own houses, which I will read to you. "On the 20th of February 1899 a boy from house "No. 20, Shukrawar, went to house No. 284, Sadashiv, "and died there of plague. The next day, on 21st "idem, a woman in house No. 20, Shukrawar, was "attacked with plague and was allowed to be treated "in the house which was disinfected on the next day. On "the 24th the brother-in-law of the woman got ill and "was removed to the Sadashiv Pet Hospital, where he "died of plague on 26th February 1899." I should like to say with regard to this first one that it is not a desirable house, nor one which one would have sanctioned in the ordinary way. They said the woman was moribund. It is not a house one would deliberately have chosen.

Major W. L. Reade, R.A.M.C.

20 Mar. 1899.

25,829. In this particular case you left the patient there because she was moribund, and not because the house was a particularly good one to try experiments with?—Quite so. "At house No. 78, Shukrawar, on "the 13th of February 1899, one case of plague occurred "in the house. On 19th February a boy in the same "house got plague, and was allowed to be treated in the "house, which was disinfected the next day. The father "of the boy died of plague in the house on 24th February. "On the 27th the brother of the patient caught plague, "and was sent to the hospital, where he died. The "patient died on 1st March 1899. Next day the wife "of the boy's brother got plague and died the same day "in the Sadashiv Pet Hospital." My conclusions with regard to treating patients in their own houses are as follows:—I think that, unless it is possible to assimilate a private house to the condition of a Plague Hospital—it ought to be detached, or more or less detached—I do not think it is possible to treat any large number of people in their own houses. These two houses caused me a great deal of anxiety. One had to tell off a soldier to constantly disinfect the floors. I admit that the floors were properly disinfected, but one could not daily look after the infected clothing, and the hundred and one things which have to be done in a Plague Hospital. Then there is the question of a guard. As it is extremely difficult to place a house under the same condition as a hospital, personally, from the little I have seen, I do not think I should be inclined to recommend the system. In fact, in Poona we have practically done away with it, because it is impracticable.

25,830. Treatment in houses under any circumstances?—If you have a bungalow in a cantonment surrounded by a good compound, and there are reasons for it, say, in case of a native gentleman or a native noble of high rank, where the question of expense is a bagatelle, I think it is possible to do it, but I am sure you could not do it efficiently in the case of a large number of houses in a crowded town.

25,831. You say that the system is applicable only in those cases where there is a large compound and other conveniences, and therefore in a town, where some of the houses are better than the others, you think it would be inappropriate even for the better houses?—I should be inclined to lay down that the house must either be detached or semi-detached. I do not think that in a long row of houses it would be possible. Then there is the question of rat infection. If you have an infected house in the midst of a crowded quarter, you get infection carried by rats from that house to others. Even if you bring the house under the same conditions as a Plague Hospital, in the midst of a crowded town there are more rats than you would have in a hospital, in a more or less isolated place. We have evidence now with regard to rat infection, and it shows that within a small radius there is undoubted infection by rats, though a very localised one. Rat infection has not played a large part in the recent outbreak in Poona. As a source of infection to man it is one I have had little knowledge of up to the present date, but from our recent experience in Poona I incline to believe that the influence of this infection has been much exaggerated. In house No. 5, Shukrawar, three plague cases occurred, and on disinfection of the house, which was a grain shop, 25 dead rats were discovered in a heap on the floor of one of the rooms. A row of small houses adjoining this shop were also disinfected and no further cases occurred. On March 1st a family of nine persons came from Bombay and took up their residence at house No. 1622, Shukrawar, and were placed under surveillance. On the third day a child died, and in the same room eight other persons were found ill, all of whom were sent

Major W. L. Reade, R.A.M.C.

20 Mar. 1899.

to the General Plague Hospital. The infection spread to house No. 1621, where four cases of plague occurred, three of whom died. In house No. 1623, 18 dead rats were discovered in a room on the ground floor. The house was disinfected. The inmates of this house, on discovery of the dead rats about 8th March, left the house, with the exception of the head of the family, my head clerk, who remained. He developed plague on the 17th and died on the 19th. No more cases of plague occurred in the neighbourhood of these houses. These instances are cited, as they go to show that infection by rats would appear to be of a local character.

25,832. Is that all you wish to put before us?—That is all.

25,833. (*Mr. Hewett.*) Could you separate the figures, so as to show the total reported cases of plague and deaths, and the total mortality, and the average mortality, from the time that we went to Poona up to now?—I have a statement of the actual total mortality from the 14th of February, which was the date of the outbreak, to the 17th of March, and also one showing the mortality for the same period in the years 1891 to 1895. They are as follows:—

MORTALITY.

STATEMENT of FIGURES of NORMAL and ACTUAL TOTAL MORTALITY from 14th February to 17th of March, during the Years 1891 to 1895.

Date.	1891.	1892.	1893.	1894.	1895.	Total.	Average of 5 Years.	Total, 1899.

25,834. The total mortality is 714, compared with an average of 248?—Yes.

25,835. What was the number of ascertained plague deaths?—There were 290 cases and 228 deaths, according to the following statement:—

STATEMENT of RECORDED ATTACKS and DEATHS from PLAGUE from 14th February 1899 to 17th March 1899.

Month and Date.	Poona City. Imported. Cases.	Imported. Deaths.	Imported. Whence imported.	Indigenous. Cases.	Indigenous. Deaths.	Total. Cases.	Total. Deaths.

Total	26	24	—	264	204	290	228

25,836. The number of ascertained deaths from plague amounts to half the excess mortality?—Yes.

25,837. (*The President.*) How do you account for the other deaths?—During January and February we have had an extremely virulent outbreak of measles and influenza—diseases, more particularly, which cause bronchial affections among children.

25,838. Has the mortality among them been excessively large?—There were 208 deaths among children under the age of five in January.

25,839. What was the ordinary average in other years?—Fifty-nine.

25,840. (*Mr. Cumine.*) As regards the two instances which you gave us of treating plague patients in houses, did you give them to us because they are the only two instances, or because they especially illustrate the danger of leaving patients in houses?—They were the only two cases that were treated so.

25,841. As a rule you remove all patients, except the moribund, to hospitals?—Yes.

25,842. Do you find that the knowledge of the fact that patients will be removed to hospital produces concealment of plague illnesses?—I do not think so.

when the case is known to be plague. Directly a case is diagnosed as plague the relatives are very anxious to get rid of it in Poona. If you go to a house and say it is a case of fever, they say, "Will you leave it until "definite symptoms have come on"? But if you say it is a case of plague you never have any difficulty. They are generally quite ready to have the person removed. We have generally explained to them that even if it is a case of fever it is very necessary that it should be under observation. Directly any definite symptoms develop there is never any further argument. That is the general rule.

25,843. Do you find that the people conceal the illness as long as possible, or do they report it as soon as it appears, even though it has not shown definite symptoms of plague?—Latterly they have done so. On the other hand, we have certainly had a great many corpses in the town; but I have attributed that a great deal to the extreme virulence of the disease. The ordinary history of an attack would be this: The man would be apparently pretty well in the morning; he is attacked in the afternoon; and is dead either the same evening or on the following morning. We have had very numerous instances of that kind.

25,844. In the two cases where you left the patients in the house, did you put them upon beds, or did they lie on the floor?—In both cases, which were sanctioned, as it were, officially, the patients were on the floor.

25,845. Did you give them any pans of disinfectants for the sputum and excreta?—Yes, we gave them everything we could in that way. I was extremely busy during that period. I told off a soldier to go there, and gave him directions what to do. Of course, I cannot answer for personal supervision. I can only say that the instructions I gave were carried out by the soldiers as far as possible. Even with this precaution the cases caused me great anxiety.

25,846. Were directions given to sprinkle disinfectants upon the floor daily?—I tried to take all the ordinary precautions that are taken in a Plague Hospital.

25,847. Do you find that plague reappears among the contacts on their return to sleep in their houses after 10 days?—I have not had a single case beyond the incubation period.

25,848. Before they are allowed to return, that is to say, in the course of these 10 days, has the room where the case occurred been disinfected only on one occasion or repeatedly?—Only on one occasion.

25,849. (*Prof. Wright.*) Of the 290 plague cases that have recently occurred, do you know how many were derived from plague existing in Poona when we were there, and how many were derived from freshly-imported cases?—To put it roughly, each imported case would do a certain amount of damage. We have the evidence I have given you of one child coming into a house.

25,850. When we were in Poona there was one focus of infection, which had been caused by an imported case; since then there have been a great many imported cases, and, of course, you have to deal with these new foci of infection. Can you find out how many of these 290 cases occurred in houses in which imported cases died—and how many have occurred in houses into which no imported cases can be traced?—It is not possible to get the information even approximately. The imported case on 14th February 1899 was the cause of 25 attacks before the disease was stamped out of the infected quarter.

25,851. Your excess mortality was 228 cases due to plague, and 238 deaths which were not due to plague?—Yes.

25,852. The latter 238 cases would labour under the suspicion of being plague cases?—Yes.

25,853. Could you rebut that by showing that very few plague cases originated in those houses in which the 238 deaths occurred which you do not attribute to plague? I want to find out whether there were any deaths from plague, or whether cases of plague subsequently occurred, in these houses which were not disinfected because the deaths that occurred in them were regarded as non-suspicious deaths?—I put in a statement, as follows:—

Pet.	Number of Houses in which suspicious Deaths occurred from 1st December 1898 to 28th February 1899.	Number of Houses in which occurred ordinary Deaths from 1st February 1899 to 16th March 1899.	Number of Houses in Column 2 in which Plague subsequently occurred.	Number of Houses in Column 3 in which Plague arises subsequently occurred.	Time which elapsed between the suspicious or ordinary death and the plague death.		
					Under 10 days.	Under 15 days.	Over 15 days.

25,854. Are the contacts only kept under observation?—They are sent to camp, where their clothes are disinfected; then they are allowed back to their houses, but they must return to camp at night.

25,855. How soon are they allowed to go away entirely from the contact camp?—After three days they are put on the "contact surveillance register" of the Pet they live in. We make a person sleep for three nights in camp, and then a notice is sent to the Chief Volunteer of his Pet: "This man is transferred from "the observation camp; take him on the surveillance "of your Pet."

25,856. (*The President.*) Under what circumstances have you had to re-disinfect a house?—If one of the people during the period of observation developed plague, the house would, of course, be re-disinfected.

25,857. That is to say, a person who had access to one of these disinfected houses is sometimes found to develop plague, and in that case you have to disinfect the houses?—If a person develops plague after an original attack the house is again disinfected. A family, we will say of five people, are sent to the observation camp. Two days after observation one of them is found suffering from plague; he is sent to the Plague Hospital and his house is again disinfected, as he is one of the family of the same house.

25,858. Has that person been in that house which you are going to re-disinfect, or has he been in the camp all the time?—He has slept in the camp at night and in the day time been in the house, and after three days he is allowed to occupy the house day and night.

25,859. At what intervals after the houses are re-entered have attacks occurred?—Attacks varied from the first day up to the sixth.

Major W. L. Reade, R.A.M.C.

20 Mar. 1899.

25,860. What has been the progress of the plague on the occasion of the third outbreak here? Is it extending rapidly or slowly? Would you have expected it to extend more rapidly, or has it extended in the same way as in the first and second epidemics?—I consider the feature of this outbreak is its very rapid spread, in fact it is quite different to the former outbreaks in Poona, and all outbreaks of plague of which I have had experience. The cause of this outbreak, an imported case from a Bhatia's family, infected 25 other cases in a few days' time, before it was possible to stamp the disease out of the infected quarter. One of the prominent features of this disease, *i.e.*, its slowness of progression, has not been found true in this outbreak. The second and also the present epidemic of plague in Karachi may be cited as evidence in corroboration of this statement. It would appear that the disease, having once got a favourable soil for its propagation, increases in virulence with every repeated outbreak. The recent outbreak here is the most virulent type of the disease that I have seen.

25,861. You have, however, the advantage of the circumstance, that you are now dealing with plague at the commencement of the hot season?—Yes.

25,862. Is it not a fact that at that time you generally have found that plague does not extend very rapidly?—At Karachi they had a virulent outbreak in very hot weather.

25,863. What has been your experience at Poona in the previous outbreak?—The 1896-7 outbreak was got under before the end of May.

25,864. That is to say it subsided in the hot season?—It commenced earlier than on the present occasion.

25,865. I believe you have had a great deal of voluntary co-operation in Poona?—Yes, a very large amount.

25,866. Is that more intelligently and more effectively being applied during this third epidemic than during the previous epidemic?—I think it is very much. All the Pets showing the best results and the best organisation are those in which voluntary agency is more largely represented.

25,867. Do you attribute some of the relative success in dealing with the epidemic on the present occasion to the greater efficiency of voluntary co-operation?—Certainly, I do.

25,868. How do you account for this voluntary co-operation being now more effective, efficient, and hearty than it had been on previous occasions?—I think it has only been developed towards the middle portion of the last epidemic; ever since then it has been kept up. In the first epidemic there were volunteers, but there was practically no voluntary organisation.

25,869. At the same time I suppose the people in Poona have more true information than they had before as to what your aims are, and what plague means?—Certainly they have.

25,870. And they have reason, therefore, more heartily to co-operate?—Yes.

25,871. They know that whatever you are doing is being done as far as possible for their good?—Yes.

25,872. They appreciate that?—I think they do.

25,873. I suppose while the epidemic is going on you cannot give any decided view as to the success of your methods?—I think they are extremely hopeful.

25,874. You appreciate the fact, however, that the epidemic is now decreasing?—I do not say that. Until it diminishes in Bombay, of course, we have to look out for a great many imported cases. I think we have been able to cope with our imported cases, and the amount of infection which has spread from them.

25,875. But your information has not been enough to enable you to judge absolutely?—No, I could not say that.

(Witness withdrew.)

Mr. S. R. Arthur, I.C.S.

Mr. S. R. Arthur, I.C.S., recalled and further examined.

25,876. (*The President.*) I believe you wish to give us some information in addition to that which you gave in your examination here on the 11th of February?—Yes, regarding inoculation in the Kolaba district, of which I am, at present, Collector.

25,877. (*Prof. Wright.*) Would you describe the circumstances under which the inoculations were done?—Yes. Inoculation was commenced at Alibag on 2nd February 1899.

25,878. What is the population of Alibag?—According to the last census, the population of Alibag is 5,888, but owing to the visitation of plague in two consecutive years I think it is probable that, even before the present attack, the population was less. The average population is now about 5,000, I should think. Since the inoculations commenced 1,385 persons had been inoculated, men, women and children, including old men up to 90 years of age, and infants two months old. The present attack commenced on the 24th December, and was heralded by a mortality among rats. As far as I have been able to ascertain, the disease was not imported, but started spontaneously, presumably from last year's germs which have meanwhile remained dormant. On the first cases occurring there was a considerable exodus of well-to-do people, including nearly all the non-official Municipal members. At the beginning of February 1898, I issued an order that no one uninoculated should sleep in the town at night, and that those who did so would be prosecuted if discovered. Latterly, the greater part of the population have been encamped in huts outside the town. When inoculation was first introduced the people were much afraid of it, and all sorts of rumours as to the evil effects of inoculation were in circulation. The results, however, have been so successful that I think this fear is now entirely removed. I will now lay before the Commission a few of the most striking instances of the immunity enjoyed by the inoculated as compared with the uninoculated. The first instance I can give is this: On 21st February there were in the Police Lines about 130 inoculated persons, and about 21 uninoculated. They were being gradually inoculated, but these 21 had remained till the end. One of these, Rakmi, wife of Gangnak, Head Constable, was attacked with plague on the above date and died on the 22nd. Another, Rama Shripatrao Sinda, was attacked on the 18th and died on the 24th—two cases. The remaining persons then uninoculated were inoculated within the two or three days following, and though 150 persons have since been living in the lines, and are living there now, there has only been one other case of plague there. This was Parbati, wife of Ragnak Rannak, who, having been inoculated a fortnight previously, was attacked with plague on the 8th of March. She had high fever one day, was better the second day, and on the third day she was almost well; and within a very few days was restored to perfect health. Beyond that there has not been another case in the Police Lines.

25,879. Are these police lines situate in an infected quarter?—Yes. It was the place first attacked. It was attacked last year also. The second instance I wish to bring to notice was also a striking one. A Koli family of seven members was living in the town, of which six members had been inoculated in February. The remaining one, Hasu, wife of Nathu, having been delivered of a child only two months ago was uninoculated. She caught the infection about the 8th instant, and died on the 14th in hospital. None of the other members of the family were affected, and the child was weaned from her, inoculated, and is now thriving. The third instance is also that of a Koli family of three members living together in the town. Of these, two were inoculated on the 9th and 17th February respectively. The third, a little girl of 12 years of age, who was to be inoculated later, was attacked with plague on the 1st instant, and died on the third. The other two members were not affected. The fourth instance is that of a family of goldsmiths living in the town. Govindshet was inoculated in February. His daughter. Rembai (uninoculated) was attacked on the 7th instant, and died on the 8th. His wife, Bhagirthi, was inoculated the same day, and has not been affected. The fifth instance is that of a Musalman family of eight; of these, three were inoculated in February.

Ismail, the son of one of them, eleven years of age uninoculated), left Alibag on the 2nd and showed symptoms of plague on the 4th. He died on the 14th. The remaining members of the family were inoculated on the 4th, and none of the seven members now remaining have been attacked.

25,880. (*Dr. Ruffer.*) Had they been inoculated before that first case or after?—Three were inoculated before, the remainder were inoculated on the case occurring. When inoculation was first introduced in Alibag, I did not allow the members of affected families to be inoculated, lest the plague should be incubating in them, and lest their death from plague should be wrongfully ascribed to the effect of inoculation, but latterly, inoculation having become more popular, I have revoked this order, and have allowed the families to be inoculated, and have then allowed them to go to their homes instead of being segregated. Sixty-seven persons, who would otherwise have been segregated as contacts have been set free, and there has not been a single case of plague amongst them. The experiment was, perhaps, a somewhat hazardous one, but it has, I think, been justified by the result.

25,881. (*Prof. Wright.*) Have you any figures to show how many cases you expected among these 67 contacts?—I could not say how many, but I should certainly have expected some cases in the ordinary course.

25,882. Is that an inference from what you have seen in other contact camps? — Yes. Generally some members of the family are attacked here and there; but the fact that among the 67 not one was attacked seems to be extraordinary, and I ascribe their immunity to inoculation.

25,883. In your case these contacts are left in the houses?—They get a certificate from me that they have been inoculated, and they are allowed to go where they like.

25,884. They are not removed from the source of infection into camp?—No. They were exactly where they were before. Among the whole of the inoculated population of Alibag there have up to date been five deaths. Of these, three have been certified to be due to natural causes, while two have been due to plague. Of the latter, both were attacked within eight days of inoculation. One, Natu Koli, was inoculated on the 10th, had high fever with perpetual vomiting for three days and died on the 13th, three days afterwards. He had no buboes, but as there were two deaths among the uninoculated near his hut, just before, it is almost certain that he died of plague contracted prior to inoculation. The other person who died of plague after inoculation was one Balaji Bandhari. He was inoculated on the 5th, attacked with plague on the 12th, and died on the 14th. Other cases occurred in the neighbourhood among the uninoculated, and it can be taken as probable that he had caught the infection prior to inoculation. The total number of attacks and deaths from plague in Alibag since the 24th of December is 71 and 61 respectively, and, if the period up to 31st January be excluded, for the remaining period they number 54 and 47 respectively. If the fact that I ordered the evacuation of Alibag by all persons not inoculated at the beginning of February—that subsequent to that a very small proportion remained, and that a few prosecutions reduced even that small proportion—be taken into consideration, it will be seen that the mortality among the uninoculated living in Alibag has reached a somewhat high percentage. And yet, at the present time, some 700 uninoculated people are living in the town with impunity. I think the above recorded facts testify strongly to the value of inoculation.

Mr. S. R. Arthur, I.C.S.

20 Mar. 1899.

25,885. You are not able definitely to get at the numbers of the uninoculated living in Alibag?—There cannot be more than a very few indeed. I went round the town myself at night about a month ago. I think we got 40 people then.

25,886. You think there may be a hundred or two?—I do not think there are anything like that. Four persons were prosecuted, and since then I think there are very few indeed—mostly those remaining are uninoculated members of families which are undergoing inoculation, and who will be inoculated afterwards. I should not think there are more than 20 people in Alibag now who are not inoculated.

25,887. (*Dr. Ruffer.*) Is plague going on now?—Yes.

25,888. Then plague must be going on amongst the inoculated, if they are all inoculated?—Cases are now occuring principally among people in the huts outside Alibag.

25,889. (*Prof. Wright.*) Now and then every day or two, you get a case amongst the uninoculated people remaining in Alibag?—Yes, up to the last few days.

25,890. Did you get very severe symptoms sometimes after inoculation which frightened the people?—No, mostly not. There was high fever often for one day. Generally, the fever subsided in 48 hours. Of course those inoculated had swollen arms for some little time. One man had very high fever and required some attention for three days. He has recovered completely. I am not aware of anyone having suffered from inoculation.

25,891. Have there been any cases in which there has been very little reaction?—Yes, I have heard of such cases: chiefly old men and little children who were given less doses.

(Witness withdrew.)

Lieut.-Colonel E. Lawrie, I.M.S., recalled and further examined.

Lieut.-Col. E. Lawrie, I.M.S.

25,892. (*The President.*) There are one or two matters on which we desire some further explanations from you?—Yes.

25,893. (*Dr. Ruffer.*) Do you wish to add anything to the evidence which you gave in Hyderabad—to the first proof of your evidence which was sent to you?—I have had a second proof sent to me, and I do not wish to add anything to that.

25,894. We examined Dr. Mullunnah with regard to a "Memorandum on experiments on rabbits with "Haffkine's fluid, performed by order of the Plague "Commissioner, Hyderabad."* I only want to ask you one question about that. In paragraph 6 of your statement you said, "The effects of inoculation of the "sterilised fluid in rabbits, and also, as far as our "limited experience goes, in man are simple. It "produces 'reactionary' fever alone without, as a "rule, any evil consequences. The question is, What "is this 'reactionary' fever due to? There can be "little doubt that it is due to plague." Will you tell us the reasons why it is due to plague?—I do not see what else it can be.

25,895. You say, further on, "One of us, Mullannah, "says it is due to the plague toxines"?—My opinion is that it produces a mild attack of plague. He preferred to put it that it was due to the plague toxines, and as he objected to put it my way, I put in his statement as well as my own.

25,896. What evidence have you got to show that it is plague?—It is not curative at all; there is no evidence except the effect that it acts as a prophylactic.

25,897. Supposing you take another disease—supposing you take diphtheria, for instance, and supposing you filter a culture of diphtheria, or sterilise a culture of diphtheria by carbolic acid, you get a certain amount of immunity, but you would not say you gave the animal diphtheria?—What else would the immunity arise from? You mean the products?

25,898. Yes?—But do not they necessarily produce the disease?

25,899. Not necessarily. It does not produce the disease. You would not say that animal had diphtheria, would you?—I should say if it was produced by the toxines, that it would be a modified form of the disease.

25,900. In the same way you say it is a modified form of plague?—Yes.

25,901. But you do not find the plague bacillus?—No.

25,902. So that this form of plague could not be contagious to other persons?—I should think not.

* *See* Appendix No. LXIX. in this Volume.

Lieut.-Col. E. Lawrie, I.M.S.

20 Mar. 1899.

25,903. I also want to ask about cotton. We have had it in evidence from Dr. Mullannah, that, in his opinion, he was not able to isolate the bacillus of plague from the cotton he examined. Are you still of the opinion that the bacillus that was isolated was the bacillus of plague?—Yes.

25,904. Why do you think so?—Because it had exactly the same appearance as all the other preparations of the plague bacilius that I have seen.

25,905. You have based your diagnosis on the microscopical examination alone?—I did not see anything else. I know that he was not able to propagate the bacillus afterwards, but I also know that in this cotton, in which he got the bacillus, there were numerous other organisms; and I thought it was quite likely on that account that it was not susceptible to propagation

25,906. He was unable to reproduce plague with this?—Yes.

25,907. So that the only evidence of plague you have got so far is the microscopical appearances of the culture?—And the death of the rabbit in which the plague bacillus was found.

25,908. In which that bacillus was found?—What I called the plague bacillus.

25,909. Do you think that is sufficient to make a diagnosis of plague?—It satisfied me completely at the time, but I reported the matter to the Commission for further investigation.

25,910. (*Mr. Hewett.*) When you were before us before, I asked you a question as to railway inspection, and I asked you to provide the figures from the 1st of October, showing the number of persons examined, and the number of persons detained, and the number of persons who developed plague in each case?—Yes.

25,911. Dr. Mullannah produced a statement (*see* Question No. 5,789) the other day—I do not know whether it was on your authority—in answer to that question?—I believe the number of passengers was omitted in that.

25,912. Will you supply us with that information?—Yes. It was subsequently intimated that all through passengers, as well as those who alighted at stations, were examined, but as no record of the number of through passengers is kept, the number of persons examined cannot be exactly stated. It is estimated that not less than 12,000 persons are examined during the month, making a total of 180,000 in a year and a quarter.

25,913. (*The President.*) I want some information from you with regard to the progress of plague now in the Hyderabad State?—We have got a hundred villages infected in the Naldrug, Gulburga, Lingsagur, and Kopbal divisions.

25,914. Is it increasing or diminishing at the present stage?—A lot more villages were infected in the last cold weather, but the villages that are infected we have now got well in hand, and it is not spreading.

25,915. What is the condition of plague in Hyderabad city itself?—There has been none in Hyderabad city.

25,916. How do you account for the non-appearance of plague in Hyderabad city?—We have had pretty strict detention on the railway, and the roads from the infected areas are so bad that infected people cannot travel into the city.

25,917. It is therefore very easy to isolate the city?—Yes, comparatively.

25,918. Of course, people are entering the city constantly from the outside, and I suppose from infected areas also?—They do, but if they come from infected areas they are nearly always detained at Gulburga or Raichur, and if they come into the city they are kept under observation for 10 days.

25,919. How long has plague been prevalent in the Hyderabad district?—Since December 1897.

25,920. So that these measures which you have adopted have been all this time successful in preventing indigenous plague in Hyderabad city?—Yes, they have so far.

25,921. Are these measures which you have just stated all the measures in force for protecting Hyderabad, or are there any others?—We have this cold weather, as we have had in the previous cold weather, patrols on all the roads; that is to say, every road leading from Hyderabad to the infected areas has been patrolled, and the villages on either side of the road have been searched throughout the whole area leading from Hyderabad to the infected frontiers.

25,922. You have practically a cordon round Hyderabad?—We have got that ready to put on, but it has not been put on yet, because there is no plague in the villages round Hyderabad between it and the infected areas.

25,923. How many are there on each patrol?—There are eight parties, each consisting of one Medical Officer, and one Commissioned Officer, and from 5 to 10 sepoys. The previous year we sent out parties of sawars—that is, cavalrymen—but we found that those men did not do the work so well as the infantry, so this year we have changed them to infantry.

25,924. Are they in charge of the medical men?—Each party is accompanied by a medical man.

25,925. Have they been successful in discovering plague cases?—No, they have not discovered a single case.

(Witness withdrew.)

Major W. B. Bannerman, I.M.S.

Major W. B. Bannerman, I.M.S., recalled and further examined.

25,926. (*Prof. Wright.*) I believe you have some facts to tell us with regard to the results of inoculations on the 26th Madras Infantry?—Yes.

25,927. Would you describe the condition of the regiment when you went down to inoculate it?—I arrived in Belgaum on the 23rd of December 1897, and the inoculations were begun next day. I found the whole of the regiment in camp round about Belgaum, some on one side of the town, and some on the other.

25,928. Why had they moved out into camp?—Because they had been so badly attacked by plague. Within the previous six weeks they had had 78 cases with 49 deaths, and on account of this they had gone out into camp—they had vacated their lines.

25,929. Had they been long in camp when you went there?—The whole of them were out by the 23th of November. I arrived about a month afterwards—the 23rd of December; so that they had been out in camp some weeks.

25,930. This large mortality that you spoke of occurred before they moved out into camp?—Not the whole of it. The first recognised case of plague in this regiment occurred on 12th November 1897, in the person of Private 2,224, Govindasami, who died the same day. Next day another sepoy was attacked, and also died. On the 15th a drummer was attacked; on the 17th the disease appeared among the followers, a bhisti of C Company succumbing on that day. By the 21st November 13 attacks had been reported from the lines, four of these being among the sepoys. On the 22nd, B Company went into camp, followed on the 23rd by C and G, and portions of A, D, and F Companies. By the 28th the whole regiment was in camp, and the lines were being disinfected. During this transition period 15 more attacks took place, six being among sepoys. In the 10 days following removal to camp 13 sepoys and 21 among families and followers were attacked. Then the cases fell off after that, and there were only one or two cases occurring in a week by the time I arrived.

25,931. The epidemic was practically over then before the inoculations began?—Yes.

25,932. Will you describe your inoculations. Did you inoculate everybody in the Regiment?—With the exception of some 81. I operated on 1,665 out of a total population of 1,746. Those were all operated on, and the Regiment then immediately went back to their lines, the lines in the meantime having been disinfected. After the inoculations were complete, that is, on the 6th of January, they had two attacks during the first epidemic in Belgaum, one in a sepoy, and one in an European Officer.

25,933. Were those among the inoculated, or the uninoculated?—They happened both to have been inoculated, but these were the only attacks after the inoculations were complete. These both took place in January.

Major W. B. Bannerman, I.M.S.

20 Mar. 1899.

25,934. These were two inoculated persons?—Yes. There were none among the uninoculated. There happened to be 81 uninoculated, but for the next six months there were no more cases among either group. From the figures that I got from Colonel Peters, Civil Surgeon of Belgaum, of the deaths in the city and cantonment, the epidemic seems to have been at its height in January, that is, in the month when they had only these two cases in the Regiment. Then the epidemic gradually died out, till, I believe, in May there were no cases at all. Then the second epidemic began in June. It became pretty bad in July, when there were 215 deaths among the civil population. In July there was only one death in the Regiment, a sepoy, who had been inoculated in December.

25,935. What is the population of Belgaum?—I am not quite certain, but I think about 38,000 or 40,000, if I remember rightly. Then, in August, there were two cases, and in September there were two cases.

25,936. All these among the inoculated?—The two who were attacked in August were both inoculated. In September two also were attacked, one inoculated, and one not inoculated. Then in October there were four cases.

25,937. Were these among the inoculated?—They were all inoculated, except one. Then in November there were two cases, one inoculated, and one not inoculated. In December there was one case of an inoculated man. These were all the cases that occurred in the Regiment during this second epidemic.

25,938. Do you know how many there are altogether from January onwards? There were three cases among the 81 uninoculated; is not that so?—Yes, three cases.

25,939. I want to know the total mortality in the Regiment, amongst inoculated and uninoculated, so as to compare the figures?—Amongst the inoculated there were 11 cases with three deaths; in the uninoculated there were three cases with three deaths, that is, 14 cases altogether. During the second epidemic there were 1,801 people inoculated.

25,940. You re-inoculated them?—They were re-inoculated at the end of August. The second inoculations began on the 18th of August, and were complete practically by the beginning of September. Between September and November various people were inoculated or re-inoculated as they came back from furlough, or from recruiting duty, or as families came in that had been away during the first inoculations. After the second inoculations there must have been very few inhabitants of the lines who had not been operated on. Less than the 81 left after the first inoculations.

25,941. Did you do these re-inoculations?—No.

25,942. Do you know why they were undertaken?—I believe because the sepoys wanted it themselves. I spoke to a number of sepoys and Native Officers recently when I was up there, and they told me that they were just waiting for a third epidemic to break out to be inoculated for a third time.

25,943. The symptoms are not sufficiently severe to frighten a soldier off from re-inoculation?—No.

25,944. Did you see any bad results in those first inoculations among the sepoys?—No.

25,945. Did you see them after inoculation?—A great majority of them I did.

25,946. Those are all the pertinent facts, are they not?—Yes, I think so.

25,947. (*Dr. Ruffer.*) As I understand, the Regiment was first evacuated, then inoculated, and then allowed to go back?—Yes.

25,948. How many cases did you get between the evacuation and the return to the lines?—On the 22nd of November the Regiment began to go into camp. The evacuation was complete by the 28th. During this transition period 15 more attacks took place, six being among sepoys. In the next 10 days 34 cases occurred, and before the return of the Regiment to the lines was complete 16 more were attacked, making altogether 78 cases from the commencement counting the 13 which occurred before removal to camp.

25,949. How many attacks were there among inoculated people?—There were not any inoculated at that time. The inoculations did not begin till about a month afterwards.

25,950. How long after the inoculation was finished did you allow the people to go back?—They went back at once—the next day.

25,951. But the houses had been evacuated for about two months before they were allowed to return to them?—The houses were evacuated on the 28th of November, and they were all back by the 30th of December. They had been empty for a month.

25,952. Had they been disinfected?—Yes.

(Witness withdrew.)

Dr. D. Galeotti.

Dr. D. Galeotti recalled and further examined.

25,953. (*The President.*) I think that you expected, on appearing before us for further examination, to give us some notes of experiments on animals with serum obtained from five horses which had been immunised in Florence by Professor Lustig?—I spoke to Professor Lustig when he came here, about this, and he told me that he had sent to the Municipal Commissioner a memorandum about this thing. I think the Commissioner has the memorandum, and I cannot say more.

25,954. This memorandum does not contain any details; it only summarises some of the experiments, without any details. These experiments were not made by you?—No.

25,955. So that you cannot give us any further information than is contained in this report?—No.

25,956. Perhaps you will put in this statement in your evidence?—Yes, it is as follows:—

MEMORANDUM BY PROFESSOR LUSTIG, ADDRESSED TO THE MUNICIPAL COMMISSIONER, BOMBAY.

"1. Having obtained from the Italian Government leave only up to the 10th of February, I must start from Bombay, and I regret it is impossible for me to give my evidence to the Plague Commission.

"2. I beg to forward to the Commissioner a memorandum giving briefly my opinion on the different subjects on which I have been requested to express my views.

"3. Further explanations can be given by my Assistant Dr. Galeotti, Lecturer at the University of Florence, and by myself by letter, if the Commission find it necessary.

"4. The aim of my coming to Bombay has been to pay a visit to the laboratory arranged by my Assistants, Drs. Galeotti and Polverini, and to have personal information of the arrangements for the preparation of the curative serum.

"5. I am very pleased to be able to express to the Commissioner that I have found the work of Drs. Galeotti and Polverini completely satisfactory in every regard, and I should be very glad if the Plague Commission would pay a visit to this laboratory, and examine the operations for the preparation of the serum, and the experiments for the immunization of horses and other animals.

"6. Now it will be seen, from the several works published by myself and Dr. Galeotti in different and scientific papers, that we had in our researches the object of extracting from the plague bacilli a very active substance of known constitution able to induce in the animals, in which this substance has been injected, a strong local and general reaction, by means of which the serum of the blood of these animals attains specific bactericidal and antitoxic properties.

"7. Our experiments were, in the beginning, performed on animals (rabbits, rats, guinea-pigs, monkeys) and later on (July and August 1897) in Bombay and Poona with a serum prepared in Florence. With this serum we treated 30 patients in different stages of disease, and of these, 24 recovered.

"8. In February 1898, I was charged by the Bombay Municipality to prepare serum in my laboratory at Florence, and to send it here for the treatment of the plague patients in the hospitals of this town.

"9. Every time, before the sending out of the serum, I tested its preventive and curative power on rats, injecting them in the peritoneal cavity with a small quantity of a very virulent plague culture.

"10. I did not determine the minimum curative doses, because I think that such determinations have

Dr. D. Galeotti.

20 Mar. 1899.

no conclusive value, it being impossible to have a standard of the strength of the injected virus.

"11. I can only say with certitude that $\frac{1}{3}$ or $\frac{1}{4}$ c. c. of serum was able to save a white rat of 100 grammes weight, if the serum was injected under the skin, two or three hours after the intraperitoneal infection with cultures able to kill rats in 12 to 18 hours.

"12. These experiments show that the serum of the No. 4 horse was the most active and that of the No. 1 horse was the weakest.

"13. The results are in accordance with the experiments made with the same serums on plague patients.

"14. With these experiments the Plague Commission have been acquainted by Dr. Galeotti and by other witnesses who had occasion to examine the treated cases, and it would be useless to report these results.

"15. Now I have found the horses treated by Dr. Galeotti in good condition, and I hope they will give an active serum.

"16. The first essays made by Dr. Galeotti on the rats gave very satisfactory results, and these results will be communicated to the Plague Commission, together with those of the following experiments by Dr. Galeotti himself.

"17. In accordance with my personal experience on the preparation of the curative serum in general, and specially in regard to the preparation of the anti-plague serum, I must say that not all the horses are able to give a serum endued with sufficient curative properties, and that some horses are able to give a good serum, only after a long process of repeated inoculations.

"18. I believe that the strength of the serum prepared, following my method, is due to the presence in the blood of substances elaborated by the cells of the organism of the horses, during the general reaction which follows every inoculation.

"19. When the activity of the serum is in good proportion to the No. 1 strength of these reactions, the horses able to give strong reactions will furnish surely an active serum.

"20. On the contrary, the horses in bad condition of nutrition and in which the material exchange is abnormal, show, after the inoculations, phenomena of impoverishment and torpor, and are not able to give a sufficiently strong serum.

"21. For this reason, it is necessary to keep the horses quiet for some time after the first blood letting and before making the inoculations.

"22. I have requested Dr. Galeotti to give to the Plague Commission the most detailed information about the experiments which will be done on plague patients with the serum of the horses which are now under treatment, and also, in regard to the researches designed, to determine on rats, with the greatest exactness possible, the strength of the serum of every treated horse.

"23. Being requested by the Municipal Commissioner to express my opinion on the importance of rats in the diffusion of the plague, I offer the following:—

"1st. I have performed experiments on hundreds of rats of different races, and living in the most different conditions, and I have found that almost all are able to get plague.

"2nd. Keeping in a cage several infected and non-infected rats, all die in a short time, and in their bodies plague microbes are always to be found.

"3rd. Mixing a virulent plague culture with the food given to some rats, all these generally die from plague, and it is quite common to find the bacilli in their fæces.

"4th. Generally, in the infected rats, the microbes enter the blood, and with great facility they pass into the urine. Thus this urine becomes a very infectant liquid.

"5th. In 1897, I had occasion to examine at Poona some dead rats found in a granary, and in these I found plenty of microbes. I investigated also the corn of this granary, but I did not discover any plague microbes in it. Nevertheless, I know that two cooks who ate of this corn died from plague a few days after.

"6th. I believe that the rats represent one of the important means of diffusion of the disease, because they are able to carry everywhere virulent microbes.

"7th. That the destruction of the rats is one of the most important measures to be taken against the plague. For this purpose poisons can be very useful, and specially would it be useful to provoke amongst the rats another epidemic, with a microbe not virulent to man. For this purpose I believe that the Laser's microbe would be the best, because it was used with satisfactory results in Thessalia some years ago. I got a culture of this microbe and tried it on white mice, and obtained a culture which was very virulent, but I had not success into the black rats. I know that the same was experienced by Dr. Galeotti, to whom I sent one of my cultures of Laser's microbe. Dr. Galeotti will receive in a short time from Prague another more virulent culture of the same microbe, and will repeat the experiments."

25,957. I think you spoke previously of 24 patients who had been treated at Poona with the serum, but you were not then able to tell us what was the nature of the individual cases, whether they were mild, or whether they were severe, or at what stage in the course of the disease the serum treatment had been adopted. Can you now give us these points of information?—I was not in Poona, and I had only had verbal information from Professor Lustig, and he told me that the cases were of different strength. Some of them were very serious, and some not very serious, and that for the most part they were all of the bubonic form, one or two being of the pneumonic form.

25,958. You cannot say anything more definite; you have only got the information from another source, not from your own observation?—That is so.

25,959. I think you also told us that you were then engaged in endeavouring to produce a more active curative serum?—Yes.

25,960. Would you tell us what stage you have reached in that production now?—I have had six horses here from the beginning of November, and I have tried now the serum of five horses.

25,961. How long did you continue the process of immunization from the beginning of November?—Till the end of January, three months.

25,962. What was the maximum quantity of virus which you were able to give these horses ultimately?—I inoculated the horses five or six times, injecting a different quantity each time.

25,963. A larger quanity?—Not very large.

25,964. Was the second quantity larger than the first, and the third larger than the second, and so on?—Yes, always increasing the dose. The biggest dose I injected was two grammes and a half.

25,965. Of what?—Of the substance which we inject into the horses in order to immunise them.

25,966. What was that substance?—A nucleo-proteid, extracted from the microbes of plague, following the method I have described to the Commission.

25,967. A concentrated toxine?—Yes, a pure toxine.

25,968. Free from anything living, therefore without any living organisms?—Without any living microbes.

25,969. Have you any idea what is the quantity of it which is required to kill a horse?—One of my horses died a few hours after the immunising injection of 49 centigrammes.

25,970. That is a great deal more than the smallest quantity required to produce death?—Yes.

25,971. What was the largest quantity of this fluid which you ultimately injected?—I could not inject more than two grammes and a half because the horses suffer very much from this injection.

25,972. Two grammes and a half produced all the initial symptoms of the first injection with the smallest amount?—Yes, very big swelling, very big œdema in the place of the injection, and afterwards a high fever in the horse, and for some time after, the place of the injection has formed a centre of large exudation.

25,973. The local effects were very pronounced?—Yes, and sometimes there was necrosis of the skin of the horse.

25,974. Was there anything further, any other general symptoms?—The animal does not take its food, and it is very weak.

25,975. Did it lose weight or not?—Yes, it lost weight very much.

25,976. Have you tested this substance against the living organism as well as against the toxine?—No, it has no effect on the living bacteria.

25,977. What effect has the serum obtained from the horse?—The serum of the horse has bactericidal

power, and the microbes are agglutinated by the serum, and they died in a short time.

25,978. Is it very actively bactericidal?—Yes, it has very great bactericidal power.

25,979. What is its anti-toxic power?—The anti-toxic power does not seem to be very great.

25,980. It is mainly a bactericidal serum?—Yes, mainly bactericidal.

25,981. Have you made any observations on human beings, plague cases, with this serum?—Yes, the serum has been used at the Arthur Road Hospital—the Municipal Hospital—by Dr. Choksy.

25,982. In how many cases?—I think now we have treated 120 cases, only I have not heard a report of all these treated cases. This report has been made, however, and has been forwarded to the Government, and I shall send you a copy in a few days.*

25,983. Can you give us the general results?—I can tell you generally the results, In the beginning the type of the disease was very serious, and, especially, there were very many pneumonia forms, and almost in every patient there was complication of the lungs, localisation of the infection in the lungs, and the first results were not very satisfactory, but now, with the serum of the horse No. 4, the results are much better.

25,984. Is that a horse which has been carried further in immunization than the other horses?—No, almost all the horses were treated in the same way, but the serum of the horse which had been used lately has given much better results, and especially for the general clinical observation of the patients.

25,985. Was the nucleo-proteid used in the first inoculation the same as in No. 4 horse?—Yes, horse No. 4 was immunised in the same way, in the same order.

25,986. With the same nucleo-proteid?—Yes, and the same result in the symptoms of the disease, especially the temperature and the action of the pulse and the action of the heart. I remember that this serum has been injected into 47 patients, and 22 of them died, but I think that almost all the remaining patients will recover. The cases treated with this serum were almost all very bad, and some of them had also a complication of the lung, and I observed the microbes in the sputum.

25,987. That is a much more favourable result than with the other experiments?—Yes.

25,988. You did altogether 120?—Yes, I do not know the exact number, but you will get that information.

25,989. There are, therefore, about 70 other patients who were treated with serum, were there not?—Yes.

25,990. But that serum, you think, was not a good serum?—I do not think that the serum was much weaker than that of the No. 4 horse, but I think the patients were much worse.

25,991. These were not such bad cases?—They were all very serious cases.

25,992. The previous cases were very serious; these last were not so serious?—These were a little milder, not very mild, because mild cases are now very rare.

25,993. While these 47 cases were being treated there were other cases in the same hospital which were not being treated?—Yes.

25,994. What was the mortality of the other cases, and what was the number of the other cases?—The mortality would be about 85 per cent., or, perhaps, more.

25,995. It was a very strong contrast, therefore, this mortality with the mortality in your cases treated with serum?—Yes, very different.

25,996. What was the dose employed? How much did you use in the 47 cases?—The doses injected were from 60 to 120 c.c.

25,997. Was that the total quantity or the dose?—The total quantity.

25,998. In what doses?—15 or 20 c.c. for every dose.

25,999. Within what intervals of time were they given?—Sometimes the injection was done twice every day.

26,000. How many hours was the second injection after the first?—For example, if the first injection has been done in the morning, the second would be done in the afternoon or in the evening, and the third in the morning of the day after. The following injections depended upon the conditions of the patients; when the patient was better, the injections were suspended. If there was an increase of the temperature, or if the patient was getting weak in any way, the injections were repeated once or twice every day.

26,001. Are these differences about the same as in the previous 70 cases?—Yes.

26,002. And the average total given to one patient was about the same?—Almost the same for every patient.

26,003. Therefore, the explanation of the more favourable results in the second series is, that the cases were not quite so bad?—Yes; I think it is partly due to the fact that the cases are not so fatal as in the first series, and that the serum of the fourth horse has been proved more active on animals.

26,004. Have you made any experiments on the lower animals?—Yes, on monkeys.

26,005. (*Dr. Ruffer.*) I suppose you base your serum treatment on man upon your experiments on animals?—Yes.

26,006. So that if the serum were found to be useless in animals, you would not feel justified in trying it on man?—It would depend on circumstances.

26,007. What experiments have you made upon the animals with the serum of horse No. 4?—I have tried it on three monkeys.

26,008. What kind of monkeys?—Brown monkeys. I had four monkeys, one being used as a control. I injected the monkeys with 2 c.c. of the plague culture, which was very virulent. Three hours after the injection I injected the serum upon three of those monkeys 5 c.c. to each monkey. After 24 hours I injected another 5 c.c. of the same serum.

26,009. That is 10 c.c. altogether?—Yes. Two of the injected monkeys recovered.

26,010. Were they ill at any time?—I did not take the temperature, but they refused food on the first day. After that they began to eat again, and they recovered completely. One died after six days of plague, and I found the bacillus in the bubo. The control died in five days.

26,011. Will you give us the other experiments you have made on animals?—Yes; I put in the following statements with regard to them.

* *See* App. No. LXII. in this Volume.

Experiments with the Serum of Horse No. 3.

Animals.	Weight.	Infection made on the 7th February.	Curative Injections.	Results.
White rat, 1st.	100	Piercing the tail with an infected needle.	After 3 hours, $\frac{1}{4}$ c.c. After 27 hours, $\frac{1}{4}$ c.c.	Cured.
White rat, 2nd	—	Ditto	After 3 hours, $\frac{1}{4}$ c.c. After 27 hours, $\frac{1}{4}$ c.c.	Cured.
White rat, 3rd	—	Ditto	After 7 hours, $\frac{1}{4}$ c.c.	Dead on the 10th February
White rat, *control*	—	Ditto	—	Dead on the 8th February.
Monkey A.	4 lbs.	Injection of 2 c.c. culture	After 5 hours, 5 c.c. After 24 hours, 5 c.c.	Cured.
Monkey B.	4 lbs.	Ditto	After 5 hours, 5 c.c. After 24 hours, 5 c.c.	Cured.
Monkey, *control*	4½ lbs.	Ditto	—	Dead on the 12th February.

Dr. D. Galeotti.

20 Mar. 1899.

EXPERIMENTS with the SERUM of HORSE No. 5.

Animals.	Weight.	Infecting Injections.	Curative Injections.	Results.
White rat, 1st	120	$\frac{1}{4}$ c.c.	After 3 hours, $\frac{1}{2}$ c.c. After 27 hours, $\frac{1}{4}$ c.c.	Cured.
White rat, 2nd	100	$\frac{1}{4}$ c.c.	After 3 hours, $\frac{1}{2}$ c.c. After 27 hours, $\frac{1}{4}$ c.c.	Cured.
White rat, *control*	110	$\frac{1}{4}$ c.c.	——	Dead on the 13th January.
Monkey 1	4 lbs.	2 c.c.	After 3 hours, 5 c.c. After 27 hours, 5 c.c.	Cured.
Monkey 2	5 lbs.	3 c.c.	After 3 hours, 5 c.c. After 24 hours, 5 c.c.	Dead on the 18th January.
Monkey, *control*	4 lbs.	2 c.c.	——	Dead on the 16th January.

The animals were all injected on the morning of the 12th January, with an emulsion of an agar culture of 48 h.

EXPERIMENTS with the SERUM of No. 1 HORSE.

Animals.	Weight.	Infection made on the 20th February.	Curative Injections.	Results.
White rat	—	Injection of $\frac{1}{8}$ c.c. under the skin.	After 3 hours, $\frac{1}{4}$ c.c. After 24 hours, $\frac{1}{4}$ c.c.	Cured.
White rat, *control*	—	Ditto	——	Dead on the 21st February.
Monkey C.	5 lbs.	2 c.c. of culture	After 3 hours, 5 c.c. After 24 hours, 5 c.c.	Cured.
Monkey D.	4 lbs.	Ditto	After 3 hours, 5 c.c. After 24 hours, 5 c.c.	Dead on the 28th February.
Monkey, *control*	4 lbs.	Ditto	——	Dead on the 25th February.

EXPERIMENTS with the SERUM of No. 4 HORSE.

Animals.	Weight.	Infection made on the 25th February.	Curative Injections.	Results.
Monkey, *control*	4½ lbs.	1 c.c. of culture	——	Dead on the 2nd March.
Monkey E.	5 lbs.	1 c.c. of culture	After 5 hours, 5 c.c. After 27 hours, 5 c.c.	Dead on the 3rd March.
Monkey F.	4 lbs.	1 c.c. of culture	After 5 hours, 5 c.c. After 27 hours, 5 c.c.	Cured.
Monkey G.	5 lbs.	1 c.c. of culture	After 5 hours, 5 c.c. After 27 hours, 5 c.c.	Cured.

26,012. Did you find that all brown monkeys which you injected with plague died, or that a certain number of them recovered?—The brown monkeys are not very susceptible to plague, and it is necessary to have a very virulent culture in order to communicate plague to them—a culture which has been passed through many animals.

26,013. Do you consider that a culture which takes four days to kill a monkey is very virulent?—Yes, it is very virulent.

26,014. Have you ever found a culture which killed a monkey after two days or 36 hours?—Yes, by injecting large quantities.

26,015. It is not the most virulent culture you can get, is it?—Yes; it was the most virulent I could get which I used for these experiments,

26,016. Were these experiments with the serum of horse No. 4, in which you treated 47 patients and had 22 deaths, carried out by Dr. Choksy?—Yes.

26,017. In the hospital?—Yes.

26,018. Can you tell me how many patients, on an average, come into the hospital in a moribund condition?—I think more than half the patients that are admitted.

26,019. How many come in a hopeless condition?—More than half of the patients.

26,020. So that you cannot contrast the mortality of 85 per cent. with your mortality of 22 per cent.?—I do not contrast them.

26,021. Were these 47 patients all patients whom you thought had a chance of recovery?—Some of them were injected when they were in a hopeless condition.

26,022. How many?—I cannot say.

26,023. Did you exclude all moribund cases, and all cases which you thought were bound to die?—Yes.

26,024. Did you exclude all pneumonic cases?—Yes, but sometimes pneumonia is not recognised.

26,025. Did you exclude all cases which you knew had pneumonia?—Yes, all those who had very evident pneumonia.

26,026. Some of them had secondary pneumonia?—Yes; sometimes they were injected patients who were believed by Dr. Choksy at the beginning not to have pneumonia, but who afterwards developed pneumonia.

26,027. Did you exclude all septicæmic cases?—No, because we did not examine the blood before the injections.

26,028. You say that injection had an effect on the pulse; how long after the injection did you notice that effect on the pulse?—Four or five hours.

26,029. Do you think that might not have been due to the patients resting in bed?—No, because such improvement was not observed in the patients not treated with the serum. There is also an effect on the delirium.

26,030. What is the effect on the delirium?—Sometimes the delirium subsides after the injection.

26,031. In how many cases did you find that it subsided?—In almost all the patients which recovered.

26,032. On what day did the delirium subside?—In two or three days after the injection.

26,033. It had not an immediate effect on the delirium?—Sometimes it had, but not generally.

26,034. Had it an immediate effect on the lung symptoms?—No.

26,035. How many of these patients had microbes in the sputum?—I should think two-thirds.

26,036. In the cases which you treated which had lung symptoms, how many recovered?—I cannot say.

26,037. (*Professor Wright.*) What is your evidence for the statement that your serum possesses any bactericidal power?—I have done experiments in vitro.

26,038. What did these experiments consist of?—I mixed the serum with the plague culture in bouillon.

26,039. Did you ever find by that method that all the plague bacilli were killed?—There was a decrease in the number of the colony, developed on Petri's dishes inoculated with the culture mixed with serum. After about 24 hours there generally is no more development of microbes.

26,040. With what serum did you make these experiments?—With the serum sent me from Florence.

26,041. Have you made the same experiments with the serum you have now?—I have just begun these experiments.

26,042. Did you determine whether the serum which you gave to the Commission possessed any bactericidal power?—The experiments on the subject are not yet completed. I have examined the action of the serum on the microbes under the microscope.

26,043. You saw agglutination under the microscope?—Yes.

26,044. With the serum?—Yes; I tested it several times.

26,045. Did you find that you got satisfactory agglutination with serum No. 1?—I tried No. 3 and No. 4.

26,046. Did you get satisfactory agglutination with serum No. 3?—Yes; there was always agglutination.

26,047. How much did you dilute the serum?—I only put a few drops of the serum in the bouillon culture.

26,048. Have you done any experiments on animals with the serum with which you have provided the Commission?—Yes.

26,049. With which serum?—The serum from horse No. 1 and horse No. 3.

26,050. Have you tried any experiments on man with the serum?—Yes.

26,051. With a portion of the serum with which you have provided us?—Yes. With serum No. 3, I injected 17 patients, of whom 10 died and 7 recovered.

26,052. What were your results with serum No. 1?—I do not remember because that was done by Dr. Choksy.

26,053. Did Dr. Choksy also try serum No. 3?—It was tried in the hospital.

26,054. Can Dr. Choksy provide us with the notes of the cases which were injected with sera Nos. 1 and 3?—Yes.*

26,055. Cases injected with the same serum with which you provided us?—Yes.

26,056. What experiments did you make in order to determine whether the serum possessed any anti-toxic power?—I have made no experiments in that direction in Bombay.

26,057. Have you ever found that serum No. 1 or No. 3 made the animals die sooner than the controls?—No.

26,058. Have you never seen that occur with any of the sera which you produce?—I have seen it in small white mice. At the beginning I tried to do the experiments for testing the serum on white mice, but they cannot shake off the shock of the injection and they die within a short time after the injection. I tried to inject them also with a physiological solution or with bouillon, and they died in the same way.

26,059. Do you think a horse which is itself suffering in health, that is, which has not recovered from the injection, can provide a serum capable of benefiting a plague patient?—I never tried to bleed a horse when it had still fever, so I cannot say. I have always bled a horse after the fever had gone.

26,060. But I understand you bleed your horses before they have recovered their original state of health; is that so?—When I bleed the horses they are in good condition, they have no fever, and they take their food properly.

26,061. Do you think a horse which has not yet recovered from the effects of inoculation can give a good serum?—I cannot say that.

26,062. If you found that the animals which received the serum died before your controls would you still proceed to do experiments on man with that serum?—I should repeat the experiments on different animals.

26,063. But if you tried it two or three times on different animals?—I do not think that the serum can do any harm to the patient. I think if one serum is not effective it can be completely harmless.

26,064. But if you saw the animals which received the serum dying sooner than the control animal, would you not think that the serum did the animals harm?—Yes; if I were sure to have eliminated every cause of errors in the experiments.

26,065. If you had a serum which you knew would do animals harm, would you give that serum to man?—It depends upon the conditions of the experiment.

26,066. Would you yourself take such a serum?—If the animals were really killed by the serum I certainly would not inject it into a patient.

26,067. And if the animals which were injected with the serum died quicker than the controls, you would not advise anybody else to give that serum to man for curative purposes, would you?—It depends upon various considerations.

26,068. Therefore, I ask you if you would take the serum yourself if you found it killed animals?—No, I would not take a serum proved poisonous.

26,069. (*The President.*) Have you had any opportunity of trying any anti-toxic serum, not only plague, but any other anti-toxic serum, possessing more poisonous qualities than a normal serum?—No, I have not.

26,070. You do not know that it is the case that some anti-toxic sera are more poisonous than others?—No.

26,071. Supposing it had come to your knowledge that anti-toxic sera are capable of producing poisonous symptoms as a rule, that is, that the tetanus anti-toxine or dyphtheria anti-toxine, as a rule, are more poisonous than normal sera, would that deter you from using the plague anti-toxine in the treatment of plague?—I would not use it. If these toxic properties were proved, I would not use it.

26,072. Suppose they are in existence in the anti-tetanus serum, would that deter you from using it in the treatment of tetanus?—It depends upon the gravity of the toxic properties.

26,073. Have you ever tested the toxic power of this plague serum which you have been working with? Have you administered it alone to any of the lower animals?—No, I have not.

* *See* App. No. LXII. in this Volume.

(Witness withdrew.)

Mr. C. C. James called and examined.

26,074. (*Dr. Ruffer.*) You are one of the Engineers to the Bombay Municipality?—Yes, Drainage Engineer for the City.

26,075. What experience of plague have you had?—I was first of all on plague duty under the Municipal Commissioner from September 1896 to March 1897, and then I was on the Plague Committee from March 1897 to May 1898, when I went on leave.

26,076. You put in Chart No. 1, showing the mortality from all causes which occurred in Bombay from August 1st, 1896, to March 15th, 1899?—Yes.*

* *See* App. No. LXXVII. in this Volume. The chart was subsequently continued to the end of May, 1899.

26,077. Will you kindly describe the chart?—The two upper black lines are the maximum and minimum temperatures. The thin blue line is the population.

26,078. Could you tell us how the maximum and minimum temperatures were ascertained?—They were obtained from the Observatory at Kolaba.

26,079. How was the number of the population obtained?—That was obtained from the Bombay tramway statistics, checked with the Government returns supplied by the Collector of Bombay.

26,080. What do you mean by saying they were checked by the Government returns?—The population is assumed at the start to be 850,000, which is obtained

Mr. C. C. James.
20 Mar. 1899.

in the following way:—The Census for 1891 gave 821,000 for the city. That gave us an increase of so many thousands on the previous census, and carrying that calculation forward we got a population in August 1896 of 850,000. That is carried forward, and the tramway people, taking that as correct, have worked out on their receipts a rule for population, and we check their numbers for population with the returns which the Collector of Bombay gives us every month. We find that it comes within 10,000 or 12,000—quite near enough for this purpose.

26,081. Do all classes of people use tramways?—I think practically only the working classes.

26,082. But do the lowest classes use tramways?—I think not, not to a great extent.

26,083. Then, how can the tramway statistics be correct; would the lowest and very poor classes leave the town?—There is a very large moving population here.

26,084. But you base your total population on the tramway statistics. Now, supposing a large number of people emigrated from Bombay, surely they would be mostly people who would use tramways, the higher workmen and the lowest middle-class people. Would they not leave in larger proportion than the coolies?—No, I do not think so.

26,085. Would the coolies leave in as large a proportion?—I think so.

26,086. What evidence have you of that?—I have not any evidence. That is the best information we can give you with regard to population.

26,087. It is only approximate?—Yes.

26,088. Within what number is it approximate?—Within 10,000 or 15,000. We know what people leave the city, and what people come in, because we get the returns from the railways, the steamer companies, and of the roads; in fact, the people leaving by every exit from Bombay are counted. These returns cannot be very far out.

26,089. Why do you take the tramway statistics instead of taking the figures of people leaving and coming to the city?—We take both; but the tramway company were the first to publish returns of population, and as they were found to be nearly correct we accepted them. I think that the figure given this year is slightly in excess of the actual, owing to so many persons having sent their wives and children out of Bombay.

26,090. Are the figures you give here the tramway figures?—Yes, checked with those returns.

26,091. The figures actually entered on the chart are the tramway figures?—Yes.

26,092. Will you continue your explanation of the chart?—The green line shown here is the humidity. The thick red line is the daily mortality, and the thin red line is the normal mortality based on an average of five years previous to 1896. The purple line is the velocity of the wind, and the brown line is the clouds.

26,093. Do you think there is any relation between either the maximum or minimum temperature and the mortality in Bombay?—It is difficult to form any real opinion from the chart. The chart is very contradictory. I cannot say there is any very great relation between them.

26,094. Is not the mortality greater during the winter months?—Yes.

26,095. Is it the largest in the same months in the three preceding years?—Yes.

26,096. Is not the mortality much larger now than it was in February 1897?—Yes, it is. The number of deaths is greater.

26,097. When was the highest mortality in 1896-97?—On the 14th January.

26,098. In 1897-98 it was in February, I think?—Yes.

26,099. And in 1898-99 in March?—Yes.

26,100. Do you think the population is larger now than it was in 1896-97?—Yes.

26,101. If you calculate the mortality according to the population, do you find the mortality this year is smaller than it was in the preceding years?—Yes; I put in Chart No. 2,* which shows the epidemics for three seasons, 1896-97, 1897-98, and 1898-99, with the weekly death-rate plotted per mille per annum.

26,102. So that the conclusion is that, although at first sight the mortality appears to be higher this year, it is actually lower in proportion to the population?—Yes.

26,103. Did you find any relation between humidity and plague?—Yes. Northerly and easterly winds, which are always dry, seemed generally to have an unfavourable influence, often immediately so, on the mortality.

26,104. To what you attribute that? Do you think it is possible that northerly and easterly winds, being cold, drive people into their houses?—Yes, undoubtedly. The result of that is that, instead of a large number of people sleeping out of doors, as is generally the case during the hot weather, they all sleep indoors, and moreover they shut their doors and windows. It is calculated that 350,000 people sleep in the streets here during the hot season.

26,105. Were there any special meteorological conditions just before the advent of plague?—Yes, in 1896 they were very interesting. The mean annual temperature for 1896 was 80·07, being the highest but one on record for the last 50 years. The total fall of rain for the year was 87·65 inches, which again is abnormal, being nearly 15 inches above the average of the last 50 years. These facts in themselves would, without further explanation, mean little, but it is necessary to consider the details of this fall of rain. June gave us 28 inches, being 8 inches above the average, July was 36·44 inches, being 11·7 inches above the average, August gave us 20·8 inches, being 7·5 inches above the average, and after the end of August only 1·61 inches of rain was registered, being 10 inches less than the average.

26,106. Have these same conditions prevailed in 1898-99?—No.

26,107. So that they would not explain the continuance of the plague in those years?—No.

26,108. Is there any relation between the height of the subsoil, water and plague?—There is no doubt that high subsoil water predisposes to disease; I think in that way there is a connection. There is an interesting point in Chart No. 1, I would mention, and it is the deaths from plague from August 1896 to end of June, 1897; 46,886 people died from plague. The average number of deaths for this period, calculated on five years previously, is 18,289, and the difference, 27,597, must be taken as plague. From July 1st, 1897, to May 1st, 1898, the deaths from all causes was 50,150, and the number on the average of five previous years was 24,192, and the difference—plague—25,958. From May 1st, 1898, to 20th March, 1899, the total deaths from all causes was 44,362, while the average is 25,759, and the difference, 18,503, is plague. This gives, for the first epidemic, 27,597 deaths from plague, the second 25,958, and the the third, to March 20th, 18,503 total, 72,058.

26,109. You have some other charts which you wish to put in?—Yes, the three plans of Bombay,* showing the progress of plague.

26,110. Will you kindly explain them?—These three plans represent the three epidemics. The seven primary colours have been taken there to represent months. When a case occurs in a district, unless the district is epidemic, it is shown by a coloured circle, appertaining to the month. For instance, take Byculla; in September 1896, as will be seen from the pink circle, there were 3 deaths from plague, in October 9, in November 2, and then in December the whole district became epidemic, having 112 deaths recorded as shown in the margin of the plan; in January 205 deaths occurred, in February 318, and in March 177. After the epidemic is over, the deaths are shown in a scored and coloured circle, showing that in April there were 50 deaths, in May 15, in June 6, in July 5, and in August 2. All the districts are worked in that way, so that it is possible to tell where each district has become epidemic. For instance, all these districts (Walkeshwar, Worli, Mahim, Sion, Parel Sewri) were epidemic in January. Mandvi was epidemic in October, so that you see the course of the disease, which is from south to north. That is probably because the people fled from Mandvi and that part of the city to the outlying districts. Then this plan also

* *See* App. No. LXXVIII. in this Volume.

* Not reprinted with the Proceedings of the Commission.

Mr. C. C. James.

20 Mar. 1899.

hows that the whole of the island was epidemic in 396–97, except one district, namely, the Esplanade. Those districts which escaped being epidemic last year were Esplanade, Upper Kolaba, Walkeshwar, Mahalakshmi, Sewri, and Sion. These districts have also remained practically free in the third epidemic. Sion is a large district with several small villages, and those villages in proportion to their population have suffered much more than the population of the districts in the middle of the city. The last plan, viz., for 1898–99, is very interesting, because it shows a small district called Chuckla, a crowded Muhammadan part of the city, which has only had 68 deaths recorded in this epidemic; it is densely populated. Whether that is accidental or whether the deaths have not been registered it is impossible to say. I cannot account for it. Then Mahim, for instance, is very badly affected; it is a very low-lying district, full of water; no sun gets there.

26,111. (*Mr. Cumine.*) Is it worse now than it was?—Mahim is very bad just now. I think this plan also shows a further improvement again in the number of districts which are not epidemic:—Sion, Worli, Walkeshwar, Mahalakshmi, Chowpati, Esplanade, Upper Kolaba, and Chuckla, eight against seven last year. I think there is some connexion between plague and a high sub-soil level, from the fact that in nearly all the low-lying districts where the sub-soil water is high, plague has been scarcely ever absent during the last three years.

26,112. Has the plague got out of Mandvi now?—There is not much plague there at present, it is rather a recrudescence than anything else.

26,113. (*Dr. Ruffer.*) Are the low-lying districts the most thickly populated districts?—Very often they are.

26,114. So that the larger mortality may be due either to overcrowding or to the fact of the districts lying low?—Yes.

26,115. Is there anything else you wish to add?—I have four other plans with me which show the actual houses infected in the districts.

26,116. I do not think we shall require those?—I should like to say that one of the most interesting things in Chart No. 2 is that both the previous epidemics stopped about the same time. If the third one is going to stop as the previous ones have, and as it appears to be going to do it, this would rather point to the fact that next year the epidemic will start later than it has done this year and finish again at the same time, and the following year follow the same course until the lines meet. You will see that the two lines cross one another at the end of April.

26,117. (*The President.*) Would it be possible to get the charts kept up to date?—Yes, I will endeavour to do so. (Note.—Witness supplied the Commission with additions to the charts, to bring them up to the end of May 1899, as shown in App. No. LXXVII. and App. No. LXXVIII. in this Volume.)

(Witness withdrew.)

(Adjourned till to-morrow.)

At The Secretariat, Bombay.

SIXTY-NINTH DAY.

Tuesday, 21st March 1899.

PRESENT:

Prof. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. Hewett.
Prof. A. E. Wright, M.D.
Mr. A. Cumine.
Dr. M. A. Ruffer.

Mr. C. J. Hallifax (*Secretary*).

Capt. C. G. Spencer, R.A.M.C., called and examined.

Capt. C. G. Spencer, R.A.M.C.

21 Mar. 1899.

26,118. (*The President.*) I believe you are in the Royal Army Medical Corps?—Yes.

26,119. And I think you have been engaged for some time on special work in connection with the plague bacillus?—Yes.

26,120. What previous opportunities have you had for engaging in bacteriological investigation?—I have done bacteriological work at Netley, but since then I have not done any bacteriological work.

26,121. How long ago was that?—That was five-and-a-half years ago.

26,122. In the work which you have just been doing I believe you have arrived at certain conclusions with regard to the recognition of the plague bacillus, have you not?—Yes.

26,123. Will you kindly tell us what conclusions you have arrived at?—The plague bacillus in the blood and tissues of an animal can be recognised, as a rule, with some certainty. Its characters are constant and distinctive. In a pure culture the characters of the bacillus are not at all so constant. They differ from the appearances seen in animals, and it is much more variable in a pure culture.

26,124. The bacillus as obtained from an animal affected by plague has a different appearance from a bacillus grown in a culture?—Yes.

26,125. What are the differences?—The bacillus in cultures is smaller; its shape is different; the size is more variable; involution forms are more numerous; and the bi-polar staining—one of the most constant appearances in blood—is very much less marked in the culture.

26,126. The bacillus culture is the more virulent?—I cannot say whether it is more virulent.

26,127. You do not consider the microscopic diagnosis is sufficiently conclusive?—No; I would never rely upon microscopic appearances alone.

26,128. What would you take in combination with microscopical appearances, to make yourself quite certain?—Experiments on animals, the appearance of the bacillus in pure culture, the mode of growth, and the rate of growth.

26,129. Have you found anything worthy of note with regard to the growth of the plague bacillus by Hankin's method?—Yes. I made two series of experiments with Hankin's reducing solution.* In each case I took five

* *Vide* Question, No. 8604. The solution referred to consists of:—

Ferrous sulphate	10 parts.
Tartaric acid	10 parts.
Citric acid	1 part.
Water	100 parts.

Capt. C. G. Spencer, R.A.M.C.

21 Mar. 1899.

tubes of broth and added from one to five drops of Hankin's solution, and then added the pure culture of plague to the broth. These tubes were kept at the temperature of the room and examined at various intervals for a week. Decolorisation was very slightly marked, and occurred in only one or two of the tubes. I did not recover the plague bacillus from any of the tubes.

26,130. What is your opinion with regard to the method?—It does not seem to be a reliable method for detecting the plague bacillus.

26,131. I believe you have observed the growth of plague in earth also?—Yes.

26,132. Will you state the result?—The method was as follows. Twelve small glass tubes, each pierced with a lateral hole were taken, and these were filled with earth. The earth was obtained from Calcutta, and was not supposed to be infected. They were plugged with cotton wool, and sterilised. The lateral hole of the tube was guarded with a tight-fitting india-rubber band. The earth in six tubes was saturated with sterile water, and the six other tubes were kept dry. All were inoculated with one drop of a fresh plague culture dropped on the surface. The tubes were kept at the ordinary temperature of the room in diffused light. After four days they were examined and no plague bacillus could be recovered, either from the surface of the tubes or at different depths below the surface from one-sixteenth of an inch to one inch.

26,133. By what process could that not be recovered, by microscopical examination, or what?—By attempting to grow it in broth.

26,134. Have you examined any samples of earth which you knew probably contained plague, or were obtained from places where the earth might contain plague?—Not by direct microscopic examination.

26,135. You have done it by other methods?—Yes.

26,136. What methods?—By making agar plate cultures, by Hankin's method, by cultivating in carbonic acid, and by inoculating animals.

26,137. What was the result of the agar plate cultures?—Seven specimens of earth from the floors of plague-infected houses were examined by agar plates, and the plague bacillus was not found at all. Four different bacilli, which could not be distinguished from plague by the microscope, were found. These were proved not to be plague by their method of growth. Three of them were chromogenic, and only when observed a little longer formed spores.

26,138. Were inoculation experiments made with them?—Not with them.

26,139. What was the result of your trials with Hankin's method?—Ten specimens of earth from plague-infected floors, and one specimen of dust from an infected pucka floor, were examined by mixing the earth with sterile broth and inoculating the emulsion into a series of five broth tubes containing from one to five drops of Hankin's solution. In none of these were plague bacilli found. Bacilli resembling plague in microscopical appearance were found in four of these specimens. These were tested by inoculations on animals, and we came to the conclusion that they were not plague.

26,140. You mean there was no pathogenic power?—No.

26,141. With regard to the carbonic acid method, what is that?—I examined seven specimens of earth from plague-infected floors by the carbonic acid method, and from two specimens bacilli closely resembling plague were obtained; but whether they were plague or not I cannot say, as my experiments are not completed.

26,142. Have you done anything further; have you taken other steps for identification, and inoculated animals?—I have inoculated animals.

26,143. What has been the result?—One animal inoculated with one of these bacilli died within 12 hours; but by the time it was found it was so far decomposed it was impossible to draw any conclusion from the examination. In the other case the animals were inoculated three days ago, and they are still living. Those experiments I shall repeat.

26,144. So that you are not in a position to say anything definite about that?—No. I have also examined three specimens of unsterilised garden soil to which small quantities of a plague culture had been added. From two of these three specimens I have recovered the plague bacillus.

26,145. Could you give us the details?—A small quantity of unsterilised garden soil was added to sterile broth and a pure culture of plague bacillus was added to the mixture of earth and broth. Carbonic acid gas was passed through. The tubes were sealed and incubated for from four to seven days and examined at different intervals. On examining these cultures microscopically I did not see anything resembling plague; but on making agar stroke cultures, from two of the specimens bacilli were isolated, which resembled plague microscopically. They grew rather faster than plague on agar. On inoculating animals, the animals died, and plague bacilli were found in the blood.

26,146. What were the pathological appearances in these animals?—They were inoculated intraperitoneally. One of them had buboes.

26,147. Where?—The buboes were in both groins. The liver and spleen were congested and dark.

26,148. Only one had buboes?—Yes, only one had buboes.

26,149. But in both cases you recovered a bacillus from the blood which very closely resembled the plague bacillus?—Yes.

26,150. Have you made any experiments as to the effect of saprophytic organisms on the growth of the plague bacillus?—Yes. The object of these experiments was to ascertain if any saprophytic organism could be found which influenced the growth of the plague bacillus either favourably or unfavourably. The method employed was to obtain a pure growth upon broth of the organism under examination, to filter the broth culture through porcelain, then to pour some of the filtrate on to the surface of a sloped agar tube, allow it to soak into the agar for a few minutes, and then pour it off again. Plague bacilli were then planted on the agar tube thus treated, and also on an untreated agar tube to serve as a control. The tubes were kept at the temperature of the room, and the amount, character, and rate of growth were compared from day to day, and any differences noted; 22 different organisms were isolated. These were all obtained from the floors of plague-infected houses. Of these 22 organisms 15 were bacilli, of which seven were spore-bearing, and five were chromogenic; six were cocci, three of which were chromogenic, and one was a sarcina; 15 of these organisms were tested by the above method as to their effects on the growth of the plague bacillus. In no case was any definite effect, favourable or unfavourable, on the growth of the plague bacillus detected. Bacillus coli communis was also tested by the same method. The growth of the plague bacillus in the tube treated with the filtrate of a broth culture of bacillus coli was at first decidedly retarded, but after five or six days it grew better, and by the tenth day there was little difference between the growth in this tube and that in the control tube. The experiment was also tried of growing the plague bacillus in the filtrate from a broth culture of bacillus coli. It grew slowly at a temperature of 37° C.; and sub-culture from this tube made on agar and kept at the temperature of the room grew, but very slowly at first. As tested by these methods the effect of bacillus coli on the growth of the plague bacillus is not very powerful.

26,151. Are there any other points you would like to bring before us?—Yes. I have tried the direct inoculation of animals with earth from plague-infected floors.

26,152. Perhaps you will give us information about that?—One specimen of dust from a pucka floor, and eight of earth from plague-infected floors were mixed with sterile broth, and the emulsion injected under the skin of rats.

26,153. Were the floors infected?—The earth I used was collected in sterile test tubes from floors of plague-infected rooms. As soon as I received information that a case or a death from plague had occurred, I went myself and collected the earth, in some cases before the body had been removed, and in every case before disinfection.

26,154. What parts of the floor did you take your specimens from?—As far as I could ascertain from close beside where the patient had been lying.

26,155. How many specimens did you take?—18.

26,156. Did you take specimens from only one part the floor?—In some cases from different parts, and other cases from one part.

26,157. What was the maximum number of parts?—70. Of the nine rats inoculated six survived and had symptoms; three died, two on the third day, and on the sixth day. The *post mortem* appearances re not those of plague, and no plague bacilli were und in the blood or organs, or at the sites of oculation.

26,158. What conclusion do you draw from that ries of experiments?—I have come to the conclusion at that method is not a satisfactory one for discovering plague in infected floors. I may mention at two specimens were also inoculated into rabbits. e of the two rabbits survived, and had no symptoms. e other died on the ninth day. No plague bacilli re found in the body.

26,159. Is there any other matter you wish to bring fore the Commission?—Yes. In addition to the ove experiments, a specimen of water and another of id from a pond behind the Mahratta Plague Hospital re examined. Waste water from a ward had been owed to run into this pond, and the clothing of some tients had been washed in it. Several cases of ague had occurred among people using the pond ter. Two c.c. of water injected into a rat killed in three days. No plague bacilli were found in the dy. By Hankin's method a bacillus microscopically sembling plague was found in the water. This was jected into a rat, which died in five hours, but no ganisms of any kind were found in the body. This cillus was not isolated in pure culture.

26,160. What was the pathological condition of the ad body?—There were no plague bacilli found in e body. I cannot state the exact pathological pearances.

26,161. Can you say whether there were or were not buboes?—There were no buboes. The mud from the nd was mixed with broth and injected into the rat, hich died in three days. No plague bacilli were und in the body. Hankin's method gave negative sults.

26,162. Was the quantity injected into these animals rge or small?—The quantity of water injected was c.c. In the other case 1 c.c. of broth in which a small antity of mud had been shaken up was injected.

26,163. Therefore it was rather dilute?—No, not ry dilute.

26,164. It would depend upon how much broth you ixed?—It was a pretty thick emulsion of mud and oth.

26,165. (*Dr. Ruffer.*) You said you made some icroscopical examination of earth. I do not think ou gave us the results?—Six specimens of earth from alcutta were examined microscopically. In four of ese diplo-bacilli morphologically resembling plague ere seen. In two the diplo-bacilli were exceedingly undant, some occurring in every field of the icroscope. Judging from other appearances these mples had been taken from the surface of the earth.

26,166. How can a plague patient infect the floor?—y sputum, and by the urine.

26,167. And possibly by the fæces?—Yes, possibly the fæces.

26,168. What is the largest quantity of earth which you have examined, either by inoculation or by the plate method at each examination; would it amount to a gramme, or to a very small part of a gramme?—It would amount to several grammes in some instances.

Capt. C. G. Spencer, R.A.M.C.
21 Mar. 1899.

26,169. How many grammes altogether?—I did not weigh it.

26,170. Roughly speaking, will it be 2 or 3 grammes?—Yes, quite.

26,171. So that the possibility of finding the plague bacillus in the earth will be extremely small?—Yes.

26,172. (*Prof. Wright.*) Have you come to the conclusion that the results obtained by the method of direct examination as to the presence or absence of plague in earth are likely to be fallacious?—I have formed the opinion that they are very likely to be fallacious.

26,173. With regard to your experiments of isolating plague by Mr. Hankin's solution, do you happen to know if Mr. Hankin attaches any importance to this method?—I believe he does not attach any importance to this method.

26,174. But in view of the fact that we have had evidence before us that plague has been detected by this method, you desire to record that, in your experience, the plague bacillus is generally killed off when it is treated by this method?—Yes.

26,175. So far it would be a very ineffective method of looking for the plague bacillus?—Yes.

26,176. Further, you have come to the conclusion that bacilli resembling the plague bacillus are able to survive in this fluid?—Yes.

26,177. It would therefore be a fallacious method?—Yes.

26,178. Therefore you would not lay any reliance on the method—as a method of detecting the presence of plague bacilli in fæces, for instance?—I should place no reliance on the method at all.

26,179. With regard to your methods of seeking for plague in earth, have you been more successful with the carbonic acid method than you had been with other methods?—It is the only method by which I have succeeded in isolating plague from earth.

26,180. Do you know how this method was suggested?—It was suggested by Dr. Marsh's experiments on the effect of burying plague cultures.

26,181. Would you describe accurately the carbonic acid method for detecting plague in earth; what method did you employ?—A small quantity of earth was added to a tube of broth and shaken up. Carbonic acid gas was passed through and the tube sealed, and incubated for from four to seven days.

26,182. Do you think there are high percentages of carbonic acid in the fluid?—Yes. I think it was saturated.

26,183. Do you think the atmosphere above was saturated?—Yes; I think the atmosphere above was saturated.

26,184. Has Dr. Marsh made any experiments upon the discovery of plague in earth by means of the carbonic acid method?—I do not know any details about his experiments.

(Witness withdrew.)

Lieut. Stewart R. Douglas, I.M.S., called and examined.

Lieut. S. R. Douglas, I.M.S.

26,185. (*The President.*) How long have you been ngaged on special plague work?—Since the 17th of ecember 1898.

26,186. (*Dr. Ruffer.*) You have been making some xperiments on the treatment of patients affected with ague, with Roux' serum, have you not?—Yes.

26,187. Can you tell us under what conditions these xperiments were made?—Forty-nine cases were eated at Bangalore. Every case that came into the ospital was taken, except those that were obviously ot plague, or those that were convalescent from ague—that is to say, people that had suppurating uboes.

26,188. You made no choice of the patients you noculated and those you did not inoculate?—No.

26,189. Can you put in a table of cases with the notes of all these cases that you inoculated?—Yes.

26,190. Each case has the temperature chart, the pulse chart, and the respiration chart added to it?—Yes.

26,191. And each case gives the number of inoculations, the time of inoculation, and the quantity of fluid injected?—Yes, I hand in the tables.*

26,192. Can you tell us whether you have noticed any evil effects from Roux' serum?—I have never noticed any evil effects.

26,193. Did you ever have any joint pains after the inoculation of Roux' serum?—In one case, but I did not treat it myself.

* *See* Appendix No. LXXIX. in this Volume.

Lieut. S. R. Douglas, I.M.S.

21 Mar. 1899.

26,194. Can you tell us whether you noticed any effect of Roux' serum either on the pulse, or the temperature, or the respiration?—Never a constant effect. No constant effect was noticed in any series of cases.

26,195. Can you tell us whether the effect of Roux' serum was to reduce the mortality in your cases?—At Bangalore I had to take the North Camp as a control against the South Camp. The previous mortality in the South Camp up to the date of my arrival had been 58·7 per cent. While I was there, there were 73 admissions—some of those were not plague, some were convalescents, and some died before I saw them. The percentage of deaths, during the time I was treating with Roux' serum, was 47·9 per cent. The bubonic cases that came in during that period were 39, and the number of deaths 20, giving a percentage of deaths of 51·3. The total cases treated with Roux' serum were 49, and the deaths were 31, giving a percentage of 63·26. Against that it must be said that I took all the serious cases, because the convalescents were not treated by Roux' serum.

26,196. What was the mortality in the North Camp before you came?—In the North Camp up to the 19th November—that was before I came—it was 75·13 per cent. Between the same dates as when I was treating cases in the South Camp, the percentage of deaths was 53·7. The total bubonic cases admitted during that time were 14, of whom 10 died, giving a percentage of 71·42.

26,197. So that the reduction in your mortality by Roux' serum was not greatly marked?—No, not greatly marked.

26,198. (*The President.*) What was the reduction?—We cannot tell exactly what the reduction was. The South Camp Hospital gave a better balance all along. During the time I was there, it was about 5 per cent. better in the South Camp than the North Camp.

26,199. That is, of those treated with Roux' serum?—No.

26,200. Then what about those that were treated with Roux' serum?—With regard to those treated with Roux' serum, I have no direct controls there.

26,201. You did not control the cases there?—No, not at Bangalore.

26,202. (*Dr. Ruffer.*) I think you made some experiments here with Roux' serum?—Yes.

26,203. Can you give us the result of them?—I treated 15 cases with 15 controls. They were taken as they came into the plague ward of the Modi Khana Hospital, and they were handed over to us, and we took every second one that came in,—Lieutenant Walton and myself. I treated 15, with 15 controls, and he treated 13, with 13 controls. Amongst my cases of those treated with Roux' serum, there were two recoveries; amongst the controls there were four recoveries.*

26,204. Was your experience on the whole here the same as your experience at Bangalore?—Yes.

26,205. You noticed no effect either on the pulse, or the respiration, or the temperature, or on the general condition of the patient?—No, none at all.

26,206. Nor on the delirium?—No, they seemed very much the same.

26,207. Is there anything else you would like to add about your experiments with Roux' serum?—Taking the whole of the cases treated by Dr. Walton and myself, there were 27 cases treated by Roux' serum, and 27 controls. Of those there were five recoveries in the Roux cases, and four recoveries in the controls. It works out to a percentage of 81·48 per cent. of deaths for the Roux cases, and 85·18 per cent. for the controls—practically the same.

26,208. Have you made any experiments with Roux' serum on animals?—Yes.

26,209. Could you give us the details of those experiments?—A series of experiments was made with Roux' serum and Galeotti's serum.

26,210. Give us the general results of those experiments?—The results are given in following table:—

TABLE I.—EXPERIMENTS made to TEST the PROTECTIVE POWER of ROUX' and GALEOTTI'S ANTI-PLAGUE SERA.

Number of Guinea-pig.	Amount of plague culture injected.	Amount and kind of serum which was injected.	Date on which foregoing inoculations were made.	Result.	Remarks.
Number 1 (control) -	$\frac{1}{10}$th agar tube	Nil.	18.2.99	Died 22.2.99	
„ 2 (control) -	„	„	„	„ „	
„ 3 - -	„	$\frac{1}{4}$ c.c. Roux' serum, *Note* 1 (Horse 21).	„	„ 23.2.99	
„ 4 - -	„	$\frac{1}{2}$ c.c. Roux' serum, (Horse 21).	„	„ 21.2.99	
„ 5 - -	„	1 c.c. Roux' serum (Horse 21).	„	„ 1.3.99	Much local re-action, *vide infra Note* 3.
„ 6 - -	„	2 c.c. Roux' serum (Horse 21).	„	„ 2.3.99	Much local re-action, *vide infra, Note* 4.
„ 7 - -	„	$\frac{1}{4}$ c.c. Galeotti's serum *Note* 2 (Horse No. 3).	„	„ 22.2.99	
„ 8 - -	„	$\frac{1}{2}$ c.c. Galeotti's serum (Horse No. 3).	„	„ 25.2.99	
„ 9 - -	„	1 c.c. Galeotti's serum (Horse No. 3).	„	„ 22.2.99	
„ 10 - -	„	2 c.c. Galeotti's serum (Horse No. 3).	„	„ 20.2.99	

In each case the serum and plague culture were injected within a few minutes of each other into opposite sides of the body. In each case the presence of plague bacilli in the body was verified after the death of the animal.

NOTE 1.—This serum was kindly placed at the disposal of the Plague Commission by M. Roux, of the Pasteur Institute, Paris. The following particulars with respect to the method which was employed for the preparation of this serum were also very kindly communicated by M. Roux. "The anti-plague serum from horses 21 and 31 was prepared in the following way:—The "horses first received dead cultures of plague bacilli subcutaneously; afterwards they received dead cultures by intravenous "injection. Lastly, they received living cultures by intravenous injection."

NOTE 2.—This serum, which was prepared by Dr. Galeotti for the Municipality of Bombay, was furnished to the Plague Commission by that gentleman. It was accompanied by the following note with respect to the procedure which was adopted in its preparation. "Horse No. 3 received the following inoculations of nucleo-proteid which was prepared by Professor Lustig's "process from culture of plague bacilli:—

"Nov. 23rd 1898. 0·11 grammes.
"Nov. 17th „ 0·92 „
"Dec. 9th „ 2·85 „
"Jan. 2nd 1899. 1·53 „
"Jan. 10th „ 1·59 „
"Feb. 5th „ 2,000 c.c. blood extracted. The serum was employed on plague patients in the Arthur Road Hospital.
"Feb. 7th „ 4,000 c.c. blood extracted. The serum is sent herewith to the Plague Commission."

continued on page 333.

* *See* Appendices No. LXXX. and LXXXI. in this Volume.

26,211. The general result of that experiment was that Roux' serum appeared to have a certain effect in delaying death?—Yes, considerable.

26,212. And Galeotti's serum rather the opposite effect?—Yes. There was another series of experiments done in the same way.

26,213. Can you give us those?—Nine guinea-pigs were taken, and all received the same dose of plague. Four received 2 c.c., 1 c.c., ½ c.c., and ¼ c.c. respectively of Roux' serum; another four received 4 c.c., 2 c.c., 1 c.c., and ½ c.c. of Galeotti's. The results are given in the following table:—

TABLE II.—Further Experiments made to test the Protective Power of Roux' and Galeotti's Anti-plague Sera.

Number of Guinea-pig.	Amount of plague culture injected.	Amount and kind of serum which was injected.	Date on which foregoing inoculations were made.	Result.	Remarks.
Number 1 (control) -	$\frac{1}{10}$th agar tube	Nil.	27.2.99	Died 4.3.99	
„ 2 - -	„	¼ c.c. Roux' serum, (Horse No. 31) *Note* 1.	„	„ 5.3.99	Marked local reaction.
„ 3 - -	„	½ c.c. Roux' serum (Horse No. 31).	„	„ 6.3.99	do.
„ 4 - -	„	1 c.c. Roux' serum (Horse No. 31).	„	„ 29.2.99	No cause of death detected, no plague bacilli were detected either microscopically or by cultivation.
„ 5 - -	„	2 c.c. Roux' serum (Horse No. 31).	„	„ 8.3.99	Marked local reaction, a few plague bacilli in spleen.
„ 6 - -	„	½ c.c. Galeotti's serum (Horse No. 1) *Note* 2.	„	„ 3.3.99	
„ 7 - -	„	1 c.c. Galeotti's serum (Horse No. 1).	„	„ 3.3.99	
„ 8 - -	„	2 c.c. Galeotti's serum (Horse No. 1).	„	„ 3.3.99	
„ 9 - -	„	4 c.c. Galeotti's serum (Horse No. 1).	„	„ 3.3.99	

The method of experimentation was the same as in the former series of experiments.
Plague bacilli were detected after death in all the guinea-pigs with the exception of guinea-pig No 4.

NOTE 1.—This serum was kindly placed at the disposal of the Plague Commission by M. Roux.
The particulars with regard to the method of preparation which was employed for the preparation of this serum, which were furnished by M. Roux, have been already given. (*Vide* Note 1 on page 322 of this Volume *supra*.)

NOTE 2.—This serum was prepared by Dr. Galeotti for the Municipality of Bombay. The following particulars with regard to the method of preparation were kindly furnished by Dr. Galeotti:—

Horse No. 1.

Nov. 17, 1898.	Plague-nucleo-albumen	0·18	grammes.
Nov. 28, „	„	0·57	„
Dec. 12, „	„	1·38	„
Dec. 29, „	„	3·97	„
Jan. 21, 1899.	„	1·23	„
Feb. 15, „	Bled 2,000 c.c.		
Feb. 17, „	„ 3,500 c.c.		

This horse was inspected by Professor Wright and Dr. Ruffer on March 2nd, 1899. He was then in a fairly good condition and had a sleek coat. He was said to have reacted less to the injections than any of the six other horses.

26,214. (*The President.*) What was the time between the administration of the virus and of the serum?—They were done at the same time. The serum was injected into one side, and the virus of plague simultaneously into the other.

26,215. (*Dr. Ruffer.*) Practically the same result was obtained in this case? That was Galeotti's serum from horse No. 1, and Roux' serum from horse No. 31?—Yes. The effect of Galeotti's serum was also tried on rats. Seven rats were taken, two were kept as controls, having received ½ c.c. of an emulsion of plague bacillus. All the others received the same dose. One of these rats received at the same time 2 c.c. of Galeotti's serum in the opposite side of the body; another rat received 1 c.c., another ½ c.c., another ¼ c.c., and another ⅛ c.c. of Galeotti's serum. The results of those up to date are that one control died in four days; the 2 c.c. Galeotti died in two days, and the ¼ c.c. Galeotti died in three days. In all these plague bacilli were found after death. The other control, and the remaining rats who received the serum are well up to date, and most probably immune.

26,216. Practically, that experiment agrees with the former series of experiments?—Yes.

26,217. Have you any more experiments in regard to the serum on animals?—Yes, but not as regards the protective value of Roux' or Galeotti's.

26,218. (*Prof. Wright.*) You made an experiment with the normal blood, comparing with Roux', in order to ascertain whether it had any immunizing power?—It is going on now. The control guinea-pig, and the guinea-pig which received normal horse blood, are dying. (Note by witness on revising proof of his evidence, "since dead.") The guinea-pig which received 2 c.c. of Roux' serum from Horse No. 21 is still alive, but with marked local reaction.

26,219. (*Dr. Ruffer.*) Did one receive Galeotti's serum?—No, not in that experiment.

This horse was inspected by Professor Wright and Dr. Ruffer on March 2nd, 1899. He was in very bad condition, was apparently feverish, was lame, and was covered with unhealthy half-healed sores.

NOTE 3.—Particulars of *post-mortem* examination of Guinea-pig No. 5. Abscess at seat of inoculation on left side of abdomen, bubo in left axilla. Pleural effusion on left side. Nodules in left lung. In all of these situations plague bacilli were detected on microscopic examination. No generalised infection. No plague bacilli were detected either microscopically or by cultivation in spleen, liver, or blood.

NOTE 4.—Particulars of *post-mortem* examination of Guinea-pig No. 6. Abscess at seat of inoculation on left side of abdomen. Suppurating buboes in both axillæ and both groins. Effusions in both pleural cavities. Lungs filled with hard greyish-yellow nodules. Plague bacilli were found scattered in small clumps through these nodules. Bacilli were recovered by cultivation from the suppurating buboes. Only a single colony was obtained in the cultivation made from the spleen.

Lieut. S. R. Douglas, I.M.S.

21 Mar. 1899.

26,220. Can you give us any facts as to the diagnosis of plague by sedimentation and agglutination?—Three sets of capillary sedimentation tubes were put up. Two of these were filled in with plague bacilli and with the diluted serum of a convalescent plague patient. The dilutions employed were respectively 1 in 10, and 1 in 50. Two other capillary sedimentation tubes were filled in with plague bacilli and with my own serum in the same dilutions and a further capillary tube was filled in with an equal quantity of normal saline solution, and of an emulsion of plague bacilli. In all of these the sedimentation was equal. The agglutination test has also been applied several times under the microscope, using a mixture of plague bacilli and normal saline solution as a control, and no marked difference can be seen.

26,221. So that you do not know of any method at present by which you can diagnose plague either by sedimentation or agglutination?—No.

26,222. That is a diagnostic method which is useless at the present time?—Yes.

26,223. Have you any other experiments on the same point?—With regard to Pfeiffer's reaction, that has been tried three times in the case of guinea-pigs, with Roux' serum. It gave doubtful results in the first case, and very doubtful positive results in the other two.

26,224. Would you kindly explain exactly how you did it?—A guinea pig was taken, and into the peritoneum of this guinea pig I introduced a small quantity, about 1 c.c. of Roux' serum, and about 1 c.c. of thick emulsion of plague. Then at intervals of one minute, two minutes, three minutes, and 5 minutes, portions of the peritoneal fluid were drawn off, and examined under the microscope. In the first case, I thought spherulation was seen very well, but in the other cases it was not at all marked. The same experiment was performed with Galeotti's serum, and the spherulation seemed to be fairly marked in that case.

26,225. How long was it before it showed itself?—It showed it best in five or six minutes.

26,226. Did any of those animals die?—I know of two of the Roux' animals that died, but I am not sure about the third. It was well some time afterwards when I saw it.

26,227. Can you give us any facts as to the involution forms of plague bacilli as seen in animals after death?—In a cat that was inoculated here, at the seat of inoculation there was a quantity of lymph thrown out, and in this there were some forms of longish bacilli, and they looked like the involution forms seen on agar cultures. Also in the peritoneal exudation of a guinea pig that had been inoculated under the skin, the same appearance was seen in one case.

26,228. Did you see it anywhere else?—No, those are the only two cases.

26,229. Did not you see it in the rabbit that was inoculated with the urine of a plague patient?—No.

26,230. Did not these involution forms look very much like saprophytes when you saw them first? Could they not be easily mistaken for some other kind of microbe?—Certainly.

26,231. So that there is a possibility of error?—Yes.

26,232. Have you any other facts bearing on that?—No.

26,233. Have you any facts bearing on the growth of plague in various gases?—I have some facts bearing on the growth of plague in carbon di-oxide. These researches in question were suggested by Dr. Marsh's experiments on the effect of burying plague cultures in earth. I believe Dr. Marsh also did this experiment. It was thought that CO_2 might have an influence on the growth of plague. A broth tube was inoculated with plague bacilli, and a stream of carbon di-oxide passed through it, and the tube was then sealed, a control being made from the same source at the same time. The growth in the tube containing the carbon di-oxide appeared to be more abundant two or three days afterwards.

26,234. Have you got one experiment on that or several?—Several.

26,235. In each case it was the same?—No, not in each case; the results have not been constant.

26,236. (*The President.*) What were the results in the other cases?—In some cases the tubes were contaminated, and therefore you could not get a result at all. In others there did not seem to be any difference in the growth.

26,237. (*Dr. Ruffer.*) It is not a constant phenomenon?—No.

26,238. Can you tell us anything with regard to the channels of infection of various animals? I think we had better begin with monkeys. The monkeys that you used were all brown monkeys, were they not?—Yes. Monkeys inoculated under the skin have died, as a rule, in about five days. One monkey that had a few drops of plague culture dropped into its nose, took seven days to die. In two cases in which plague bacilli were inoculated into the trachea of monkeys, they each died in three days, and in those cases the lungs were almost solid—like the lungs in croupous pneumonia. One monkey was inoculated in the vagina, some plague culture being put up the vagina, and this died in seven days, and plague bacilli were found in its organs. There was in this case a good deal of local re-action. One monkey had a small quantity of plague put into one eye.

26,239. On the conjunctiva?—Yes, on the conjunctiva, and that died in six days.

26,240. Did you find that the glands nearest to the point of inoculation were always more enlarged than the other glands?—In all these cases, except in the cases of the trachea, where there was no marked enlargement of glands.

26,241. Did you try to infect monkeys by the mouth?—No, not monkeys; but some were inoculated intravenously.

26,242. What were the results of your intravenous injections?—One monkey recovered. In one monkey, the plague bacilli seemed to have leaked into the wound and affected the glands just above.

26,243. Did that animal die?—Yes, that animal died with a bubo above the wound. Another monkey received intravenously eight-tenths of an agar culture injected by means of a glass cannula, and it died two days later with very few bacilli found in its organs, and none in its blood. Cultures were made, but I have not examined them yet. Another monkey received four-tenths of an agar tube, intravenously, and died three days after injection. It had plague bacilli in its organs—more than the one which I have referred to above—but I could not see any in its blood, and the cultures have not developed yet. Another monkey received two-tenths of a tube, intravenously, and died in four days.

26,244. Did you find any bacilli in its blood?—Yes, in that one they were swarming.

26,245. Have you any other experiments on monkeys that you can give us? I think in some cases you obstructed the circulation of a limb in which plague had been injected?—Yes, in one case. The right femoral and the left brachial artery were tied, and then into each of the four limbs ¼ c.c. of the same plague emulsion—that is one-fortieth of an agar culture—was inoculated, and that monkey died in three days. Buboes were found in all four limbs, in both axillæ and in both groins.

26,246. Were they most marked on the side in which you had tied the artery?—No, there was no difference noticed.

26,247. Have you any other experiments bearing on the same question?—The right femoral and left brachial veins were tied in one monkey, and one-fortieth of a tube was injected into each limb; that monkey took four days to die. No difference was found in the size of the buboes.

26,248. Did you find when an animal was injected, and died, after inoculation in the veins, that the blood and the organs contained more or less bacilli than when it is injected under the skin?—When the animals died quickly, there were decidedly fewer bacilli in the organs.

26,249. They died quicker than when injected under the skin?—They had very much larger doses.

26,250. You cannot make any comparison between the two?—No, not definitely.

26,251. Can you tell me anything about the presence of bronchial symptoms in plague patients during the present epidemic?—They seem to be exceedingly numerous. I think, out of my 13 cases that I treated with Roux' serum, that six or seven had bronchial symptoms.

26,252. What do you mean exactly by bronchial symptoms—not pneumonia?—No, not pneumonia.

26,253. You mean any other symptoms connected with the affection of the lungs—such as bronchitis, or œdema of the lungs?—Yes, and any slight symptoms or physical signs.

26,254. Most of those patients have a cough, have they not?—Many of them cough, but not all of them cough that have the symptoms.

26,255. Do they expectorate?—Freely.

26,256. Can you tell me anything about the presence of the bacilli in the sputum in non-pneumonic cases, in bubonic cases?—Out of 13 bubonic cases, bacilli were found microscopically seven times, and five of those had buboes other than in the cervical, or sub-mental regions.

26,257. Were you ever able to isolate it in non-bubonic case by culture?—No, not from the sputum.

26,258. But there may be quite enough microbes in the sputum to make a diagnosis of plague?—They were exactly like plague.

26,259. Were you ever able to find plague bacillus in the discharge from the nose?—In one case where the patient had sub-mental buboes, and a bloody discharge from the nose.

26,260. You were able to prove those by inoculation, were you not?—Yes, I proved by inoculation that these bacilli were true plague bacilli.

26,261. Can you tell me anything about the presence of plague bacilli in the blood?—In a total of six examinations of the blood of plague patients I found plague bacilli in three; one man recovered, one man died 24 hours afterwards, and the other died five days afterwards.

26,262. In these cases, were the plague bacilli numerous?—In the case of the patient who died the next day, they were very numerous; in the other two they were very few.

26,263. In one of them it did not grow in agar, but it did in bouillon?—Yes, in one case a growth was obtained in bouillon but not in agar.

26,264. Did you examine the pus from the buboes? Were you ever able to find the plague bacillus in a bubo which had opened spontaneously, or had been opened after suppuration?—No, never.

26,265. You found a lot of other micro-organisms, did you not?—Yes, in three cases other micro-organisms were found.

26,266. What micro-organisms did you find?—Staphylo-coccus pyogenes aureus in two cases, and a bacillus resembling the bacillus coli in other cases.

26,267. Did you find the bacillus coli in other cases resembling plague?—I found the bacillus coli in an abscess in a boy's scalp.

26,268. Were you able to find the plague bacillus in the urine of plague patients?—I examined for it in three cases. In none of these was a cultivation of the plague bacillus obtained. The method employed was as follows:—The urine was drawn off with a sterilised catheter, and passed straight into a tube of bouillon. These tubes were always found contaminated. In five cases in which the urine was inoculated into the peritoneal cavity of an animal, one gave a positive result, the animal died with typical plague bacilli in its organs.

26,269. (*Prof. Wright.*) Have you any facts that bear upon the sterility of Haffkine's fluid? Have you, for instance, any knowledge that some of the bottles are obviously putrid?—Some of the bottles when opened smelt very strongly, a very foul smell.

26,270. Do you think a putrid smell would arise if carbolic acid had been added to the particular bottles you speak of?—It might, I think.

26,271. We have had it in evidence that M. Haffkine standardises his prophylactic by shaking up the sediment, and judging of the turbidity of the fluid. Do you think it is probable that the sediment contains other substances also, in addition to bacteria?—It certainly might.

26,272. What experiments have you made to determine that there is an equal amount of sediment in the doses prescribed on the bottles?—A series of filter papers was folded up and then dried and sterilized at 110° C. in a hot chamber. They were then put into test tubes which had also been dried, corked, and allowed to cool. That done, the tubes with the contained filter papers were weighed on a chemical balance. Each filter paper was then placed in a funnel, and a bottle of Haffkine's fluid was opened, and the contents of this, after they had been measured, were filtered through the dried filter paper. The filtrate which passed through the filter was in all cases *water-clear*. The paper and the contained sediment were then dried at 110° C. This done, the filter papers were put back in the same test tubes, corked with the same corks, and allowed to cool, and then re-weighed. The difference in weight gave the amount of the sediment in the quantity of Haffkine's fluid which had been filtered. The dose which was prescribed for that particular bottle was ascertained from the label on the bottle, and the number of doses which were contained in the quantity which had been filtered was then calculated out. Finally, from these data the weight of sediment which was contained in each dose was ascertained.

26,273. Were the bottles which were tested selected at random?—Yes.

26,274. What were the results?—In all, ten bottles, derived from ten different brews, were examined. The results which were obtained are exhibited in the following table:—

TABLE III.—Showing the different WEIGHTS of SEDIMENT which may be contained in a prescribed DOSE of HAFFKINE'S PROPHYLACTIC.

Number of Brew.	Volume of the Prophylactic which was passed through the Filter.	Volume of Prophylactic which was prescribed as a Dose.	Combined Weight of the Test-Tube, Cork, and dried Filter Paper.	Combined Weight of the Test-Tube, Cork, dried Filter Paper, and Sediment.	Weight of the Sediment in total Quantity filtered.	Weight of Sediment in prescribed Dose.
4552	100 c.c.	10 c.c.	13·225 grm.	13·3065 grm.	0·0815 grm.	0·0081 grm.
6482	70 „	5 „	10·1135 „	10·265 „	0·1515 „	0·0108 „
6038	69 „	6¼ „	10·055 „	10·2075 „	0·1525 „	0·0138 „
4243	100 „	5 „	17·343 „	17·657 „	0·314 „	0·0157 „
6174	62·5 „	6¼ „	17·3565 „	17·517 „	0·1605 „	0·016 „
3923	105 „	15 „	9·129 „	9·242 „	0·113 „	0·016 „

5182	75 „	10 „	13·148 „	13·4225 „	0·2745 „	0·036 „
4823	62·5 „	12·5 „	12·2735 „	12·4675 „	0·194 „	0·038 „
5108*b*	42·5 „ *Note* 1	15 „	9·640 „	9·7995 „	0·1595 „	0·0563 „

NOTE 1.—The bottle of prophylactic which was employed for the estimation contained only 42·5 c.c. of fluid.

26,275. I understand the weight of the sediment contained in a dose of Haffkine's prophylactic is in some cases seven times larger than in other cases?—Yes.

26,276. And if the toxine in the fluid is in proportion to the sediment, it would result that one dose of prophylactic may contain not only seven times more of the sediment, but also seven times more of the dissolved toxine, than another dose of the prophylactic?—Yes.

Lieut. S. R. Douglas, I.M.S.

21 Mar. 1899.

26,277. Have you made any experiments to determine whether Galeotti's serum is more toxic than normal horse serum?—Yes, I made the following experiments:—

TABLE IV.—COMPARISON of the TOXICITY of GALEOTTI'S SERUM with the TOXICITY of NORMAL HORSE SERUM.

Number of Guinea-pig.	Weight of Guinea-pig.	Amount and Kind of Serum which was injected.	Relation of foregoing Amount to Body Weight of Animal.	Result.
	Grammes.		Per Cent.	
Number 1	230	Galeotti's serum 11·5 c.c.	5	No toxic symptoms observed.
„ 2	220	Normal horse serum 11 c.c.	5	Do.
„ 3	260	Galeotti's serum 19·5 c.c.	7·5	Do.
„ 4	260	Normal horse serum 19·5 c.c.	7·5	Do.

26,278. You draw from these experiments an inference that Galeotti's serum is not appreciably more toxic that the normal serum?—To normal animals it does not seem to be appreciably more toxic.*

26,279. In view of the fact that you found that animals that have received Galeotti's serum have died faster, when inoculated with plague, than normal animals, do you infer that there are probably unneutralised toxines in Galeotti's serum?—Yes.

* For further confirmation of this result *vide* Table V. in Lieut. Liston's evidence below.

26,280. Have you made any experiments with a view to determining whether a more effective therapeutic serum could be obtained by combining together two or more varieties of such sera?—Yes, I took two rabbits and inoculated them preventively, with a very large dose of Roux' serum. I then further gave them an injection of plague bacilli. These rabbits had high temperature after this, but they both recovered. One rabbit had received 35 c.c. of Roux' serum, and the other had received 55 c.c. After ten days they seemed perfectly well, and some of their blood was drawn off, and the serum collected. Then the following experiments was made:—

TABLE V.—EXPERIMENTS made to DETERMINE the PROTECTIVE POWER of various ANTI-PLAGUE SERA and of various COMBINATIONS of ANTI-PLAGUE SERA.

Number of Guinea-pig.	Nature and Quantity of the therapeutic Serum which was injected.	Dose of Plague Bacilli which was injected.	Date on which the foregoing Injections were made.	Result.	Remarks.
No. 1 (control)	Nil	$\frac{1}{12}$ agar tube	14.3.99	Died 18.3.99	
„ 2 (control)	Nil	„	„	„ 19.3.99	
„ 3	2 c.c. Roux' serum (horse 21)	„	„	„ 23.3.99	Much local reaction.
„ 4	2 c.c. Galeotti's serum	„	„	„ 17.3.99	
„ 5	2 c.c. serum from immunized rabbits.	„	„	„ 19.3.99	
„ 6	1 c.c. Roux' serum 1 c.c. Galeotti's serum	„	„	„ 21.3.99	Much local reaction.
„ 7	1 c.c. Roux' serum 1 c.c. immunized rabbits' serum	„	„	„ 23.3.99	„ „
„ 8	1 c.c. Galeotti's serum 1 c.c. immunized rabbits' serum	„	„	„ 17.3.99	
„ 9	0·5 c.c. Roux' serum 0·5 c.c. Galeotti's serum 0·5 c.c. immunized rabbits' serum	„	„	„ 19.3.99	
„ 10	1 c.c. immunized rabbits' serum	„	„	„ 22.3.99	Much local reaction.
„ 11	0·5 c.c. immunized rabbits' serum.	„	„	„ 17.3.99	

In each case the serum and plague bacilli were injected into opposite sides of the body. The serum was in each case injected a few minutes before the plague bacilli. In every case plague bacilli were found after death in pure culture in the internal organs.

Each of the guinea-pigs which were employed for this experiment weighed approximately 350 grammes.

26,281. Have you noticed a characteristic smell in plague cultures?—Yes.

26,282. Do you think that the smell is an important aid in diagnosing plague?—I do not think it is very important. I have never found anything smelling like it myself.

26,283. Have you made any experiment to determine whether it is possible to infect an animal with plague by means of the food?—Two experiments were made. In the one case two rabbits were taken. They each had a whole agar culture of plague, emulsified in broth, put into the stomach by means of a stomach tube. One of those died 21 days afterwards, but no plague bacilli were found in any of its organs, and neither did we find anything resembling plague. The other one is still alive. In another case, a mouse was fed upon the spleen of an infected rat, and it died. Plague bacilli were found in its organs, but you cannot say that that is a proof that it died from eating the spleen.

26,284. With regard to the monkey that died after the injection of plague bacilli into the vagina, were there buboes in the groin?—There were buboes in both groins, and the lumbar glands were very much enlarged.

26,285. Do you think that the prevalence of inguinal buboes may stand in relation with the fact that plague may be absorbed into the system by way of the genital tract?—They might be.

26,286. (*Dr. Ruffer.*) Did you try to infect a male monkey by means of the genital tract?—Yes, but it was unsuccessful. The monkey had been used for another experiment.

26,287. (*The President.*) In those experiments in which you tried the antidotal power of the serum, how did you

pproximately determine the dose of virus so as to now that you gave the same dose of virus to each of he animals?—A mass of culture plague was taken, nd a certain quantity of broth was put into that; all he bacilli were scraped off the surface of the agar, and nade into an emulsion with this broth; then it was lrawn up into a syringe, and an eqnal quantity given to each.

26,288. What was the relationship of this dose to the smallest dose which you gave of the serum? How far lid it exceed the smallest quantity?—One-tenth of a nass of culture of an agar tube was given in one case, nd in the other I think it was the same.

26,289. Have you any data to show what relation-hip the dose you administered would bear to the smallest dose that would kill the animal?—I do not know what the smallest dose is, it being impossible, as far as I know, to find out the minimum lethal dose of a living virus.

26,290. You do not know whether it was 100 times more or 50 times more?—Certainly not.

26,291. I suppose it is impossible, if you have an enormous amount of virus introduced into an animal, to prevent death, by any anti-toxic serum, in that animal?—Certainly; all the animals died. Those who were inoculated with Galeotti's serum died before the animals which had nothing but plague.

26,292. You do not know how much above the quantity that was capable of producing death, the dose of the virus which you administered in these test experiments had been?—Certainly not.

26,293. It may have been 100 times?—It may have been 100 times.

26,294. (*Prof. Wright.*) Do you infer from the fact that the controls lived for four or five days in each experiment that the dose of plague administered cannot have been very great?—It cannot have been very excessive.

26,295. Do you think it could have been 100 times?—I should think that it would have killed quicker if it had been 100 times.

26,296. (*The President.*) Did you record the weight of the animals in all those cases?—The guinea-pigs were picked as nearly the same size as possible. They were not weighed.

26,297. In the series of observations on patients which you have made, I observe that you do not always state the day of illness. Could you put that in?—It is put in in every case except one in that series.

26,298. There are two or three here in which it is not put in. Do you think it would be possible to obtain that information? If you could fill in this column it would be very important?—It is filled in on the notes if it is not filled in on the chart.*

26,299. In those cases where you have found the plague bacillus in the sputa, which also were cases in which the lungs or bronchi were affected, did you look for pneumo-cocci?—We looked for them microscopically.

26,300. Did you find any pneumo-cocci?—Certainly.

26,301. Always?—No, not always; we found it as frequently in ordinary normal sputum.

26,302. Did you examine any discharges from the nares which had not blood in them?—No. I only did one case.

26,303. Did you make any experiments by introducing the virus with food substances into the alimentary canal?—It was a pure culture that was put down into the stomach of a rabbit by means of a stomach tube.

26,304. Not mixed with food?—No.

* *See* Appendices Nos. LXXIX., LXXX., and LXXXI. in this Volume.

(Witness withdrew.)

Lieut. H. J. Walton, M.B., F.R.C.S., I.M.S., called and examined.

26,305. (*The President.*) I believe you are in the Indian Medical Service?—Yes.

26,306. You have also been engaged in special laboratory investigations with plague virus, I think?—Yes.

26,307. What are your medical qualifications?—M.B., London University, F.R.C.S., England.

26,308. Would you tell us what previous experience you have had in similar work?—I had fifteen months' plague duty before I came here; I had five months' experience of plague work on the railways, two months in Bombay city, three months at Satara, and five months in the Punjab.

26,309. What laboratory experience have you had prior to this?—I have worked at St. Bartholomew's Hospital, under Dr. Kanthack, and I have worked at Netley.

26,310. You first endeavoured to determine the susceptibility of various animals to plague?—Yes, I did.

26,311. Will you give us the information you obtained with regard to rats?—I find the Bombay rats are very frequently immune. If you have two rats and give them equal quantities of the same plague emulsion, one will sometimes die and the other will show no symptoms at all. I have notes of five rats which were inoculated with plague from a source which was known to be virulent to other rats, and they showed no symptoms at all. One rat I have now which was inoculated three times with very large doses, but it has never had any symptoms of any kind. I have also tried the effect of passing plague through rats—killing a rat with plague; taking its spleen and emulsifying it and injecting it into a second rat, and when the second rat dies, into a third and so on. I have done two series of experiments. The second series was a double series, so that practically there were three series of experiments. I have never succeeded in killing more than three rats in succession. The spleen was emulsified at once and injected at once; it was not allowed to grow in broth, it was emulsified and injected immediately. I emphasize that because I think it is possible that if a spleen were taken from a rat and then allowed to grow in broth, in a short time it might become more virulent. I have no experiments on the subject, as I have not had time. I find that by this method of taking a series of rats the first rat usually dies quickly—in three or four days; I have killed them in two days. The second and third rats generally take longer to die. I have never got beyond the third rat. One of these third rats, died after six days. Its blood and all its organs were examined but no bacilli were found at all. Its heart's blood was planted on agar and nothing grew. I have also tried to infect rats through the nose by dropping broth cultures of plague upon the nostrils. I have done that twice, but I did not succeed in killing the rats.

26,312. The result seems to show that there is no intensification of the virus?—Yes; but on the contrary, I think the virulence diminishes.

26,313. There was attenuation?—I think so. This is probably not quite the method of Nature. The spleen was taken out as soon as the animal was dead and immediately injected.

26,314. You have not endeavoured to obtain cultures from the blood or to isolate the bacillus in the blood in each of those generations?—I have in the third rat, of the second series. I did not in the first series, because I expected to kill more rats. But in the second series I did, and as I say, I could grow nothing and I could see no organisms in it.

26,315. Have you made experiments with pigeons also?—I have made three experiments on pigeons by injecting large quantities of plague under the skin, but none of the pigeons died.

26,316. Have you experimented on cats?—I only inoculated one cat. That was inoculated under the skin also and it died after six days. It seemed to be rather resistant. There was a good deal of local reaction—I think more local reaction than I have seen in any other animal. Its blood and all the organs were full of plague.

26,317. Did you give a very large dose?—Yes, it had a large dose.

26,318. What has been your experience with regard to monkeys?—I have inoculated monkeys subcutaneously, intravenously, by the trachea, by the conjectiva, and by the nose, and they have died with all those methods. The shortest time was the subcutaneously inoculated monkey which died in two days. Three or four days is about the average. I have notes here of two, three, and four days.

Lieut. H. J. Walton, M.B., F.R.C.S., I.M.S.

21 Mar. 1899.

26,319. In the case of the intravenous injection?—One monkey died after two days. Here again, I have four, four and two days. In one of those four I am not quite sure it was really intravenously inoculated; I think that the cannula may have leaked a little.

26,320. Have you administered plague virus by the digestive canal?—I have tried that on mice, but not on monkeys.

26,321. What was the usual period between stomach-administration and death?—Subcutaneously, I think, in monkeys it was between three and four days.

26,322. With regard to mice, did you find them very susceptible?—I found mice very susceptible indeed.

26,323. How did you ascertain that?—I once intended to inoculate one mouse with plague, but the tube from which I was going to inoculate it was mislaid. I had already used up the contents of the syringe on another mouse, so I pricked this mouse with the empty syringe. There might have been a very little adhering to the inside of the needle. The mouse died as quickly as the one that had received a considerable dose under the skin. Another thing is that they die very quickly. You can kill a mouse with quite a small quantity of plague in four hours. I have killed mice in four hours by injecting into the peritoneum. Under the skin, I think the shortest time was about eight hours. These were all tame mice. I have not tried any wild ones.

26,324. Did you find the virus of plague in these mice?—Yes. All the organs were full of plague bacilli and the blood was full of plague bacilli. One mouse I fed on the spleen of a plague rat. The spleen was very full of bacilli and the mouse was given water, but no other food. I examined the mouse before I put it in, and I saw no abrasions or cuts of any sort. It died in two days. Some of the spleen had disappeared. It had no other food. The spleen and the liver contained numerous plague bacilli.

26,325. Within what time did death occur?—Two days. That is the only experiment I have done by the mouth.

26,326. Were plague bacilli found in the organs?—Yes, in the spleen and in the liver.

26,327. Have you administered the virus in any other way in the case of mice?—Yes. I have injected into the peritoneum and subcutaneously.

26,328. Are those the only two ways?—Yes, and that one instance by the mouth. Those are the only ways I have tried.

26,329. You have made experiments with earth, I believe?—I did some experiments with earth to see if I could find any bacillus that resembled plague, or bacilli that were plague. Dr. Spencer was examining Bombay earth and I was trying earth from other sources. I examined a sample sent from Calcutta. There did not seem to be anything special about the history of the earth. It came from under a staircase in a house, but there was no note that there had been plague in the house. I plated this earth on agar after putting it in broth. A great many things grew, and I managed to isolate seven distinct micro-organisms. Amongst these there was a bacillus which looked like plague under the microscope. It stained in the way that plague does, and it was very much of the same shape as plague. On the original plate this bacillus grew unlike plague; I had no suspicion; it did not look at all like plague. It was a small round pale colony with concentric rings round it. It grew very slowly; I think it was six or seven days before I saw this colony on the plate. I have a note here that at the end of six days the diameter of the colony was about that of a pea. It was not a very fast-growing bacillus. The bacillus is about the size of the plague bacillus, but it differs from it in being distinctly motile. It does not show a stalactite growth in broth. Another thing I found was that if I made repeated sub-cultures on agar, in the later sub-cultures it grew very much faster, although originally of slow growth. After 24 hours there was a good growth in the later sub-cultures. It showed well-marked bi-polar staining, and it showed forms like the involution forms of plague. In fact, when I showed the bacillus to anybody I usually with a view to astonishing them, told them that it was not plague, because it looked so much like it.

26,330. Is it pathogenic?—Yes, it is pathogenic. It kills mice and guinea-pigs when injected subcutaneously or into the peritoneum. Mice die in about six hours when a small quantity of emulsion is injected into the peritoneum. I also tried pigeons and rats, but it killed neither.

26,331. Did you find these bacilli in mice?—Yes, but I find that there is some difference between this bacillus recovered from animals and this bacillus as it grows on agar tubes, although, in the former case, it is still rather like the plague bacillus. I have noticed that the blood and the organs of animals which have been killed by this bacillus show many bacilli which are usually distinctly longer and more pointed than those from cultures. In some cases this character is very marked indeed. Sometimes this bacillus stains very irregularly, especially when from the peritoneal cavity; in fact, the conditions in which it most closely resembles plague are when it is taken from a young culture on agar. Morphologically, it is then almost identical with plague. It is pathogenic; it kills mice and guinea-pigs, but it differs from plague in being motile and in being more pointed. In animals it is usually more pointed, but sometimes it is not. It looks very much like plague even from animals.

26,332. What are the pathological changes?—The animals seem to die with intense septicæmia; the blood and all the organs are full of bacilli.

26,333. There is no enlargement of the glands?—No, it produces no buboes.

26,334. You consider it is extremely like plague?—Yes. It was suggested to me that it might possibly be one of the forms of bacilli which produce lactic acid fermentation. I tried lactose broth, but it does not ferment it at all.

26,335. Are you quite certain in your own mind that it is not the plague bacillus?—Yes. I feel quite sure that it is not. It grows much faster than plague. When you look at it very critically it is not quite the same as plague. It does not produce buboes in animals, and it is a motile bacillus.

26,336. You have also made experiments as to the escape of plague from animals?—Yes, but I have not done very many, and I have not had much personal experience of it. I have tried human urine. I have done five or six cases. I once drew off some urine from a plague patient in one of the hospitals seven hours before he died. This was centrifuged, and the sediment was planted out, and I grew from that a bacillus which, in its cultural characteristics and morphologically, closely resembled plague, but it did not appear to be pathogenic, as it failed to kill a rat and a mouse.

26,337. Was it alive?—Yes, it grew. From the blood of the same case a bacillus was grown, which was apparently the bacillus of plague, which did kill rats. At another time I grew a bacillus from the urine of a dead monkey which had been killed by plague; this bacillus seemed to be that of plague. In both these cases, when plague was grown from urine, the plague grew very slowly. I have an impression in my own mind, from these cases and from other cultures I have seen from urine, that the bacillus of plague as obtained from urine grows very slowly. The first cultures, at any rate, grow more slowly when it is from urine than from the blood.

26,338. Are there any other fluids which did not retard the growth of plague?—I do not know. I have no experience of them.

26,339. Have you made experiments with sputum?—Yes. There was one case here at the Port Trust Hospital. The sputum was sent up to the laboratory one day; it contained a great many micro-organisms and also a great many bacilli which appeared to be the bacilli of plague, they were exactly like plague, under the microscope, and they stained like plague. I went down to see this case and all I could find was that the patient was said to have been ill for six days. He had the physical signs of broncho-pneumonia on both sides of his chest; there were no definite areas of dulness; there were râles and rhonchi all over his chest, and he had no bubo. He was treated by intravenous injection by Roux' serum; he had 40 c.c. The next day I heard he was very much better. I saw his sputum again; there were no bacilli like plague in it and the man recovered.

26,340. Have you found much difficulty in recognising the plague bacillus in animals?—Yes.

26,341. What are the chief difficulties?—One difficulty is that it appears to be sometimes associated with other bacilli. When an animal dies of plague, you sometimes find other bacilli in it, as well as plague

bacilli. There was a monkey which was killed by injecting plague culture into its trachea, and I made cultures from the lung, the heart's blood, the spleen, and the liver. The cultures from the liver and spleen grew like ordinary plague; the cultures from the lung, which showed a copious growth on agar after 24 hours, looked like plague when examined microscopically, with many involution forms. It was emulsified and injected into the peritoneum of a mouse, which died in four hours. In the peritoneal fluid from this mouse there was a capsulated bacillus. I think it was a bacillus, or at least, a cocco-bacillus. I tried a few experiments with the bacillus. It did not stain by Gram's method, and there was a suggestion that it might be Friedländer's bacillus. I tried this bacillus in lactose broth, and it certainly decomposed it. A great deal of gas was given off, but the gas apparently was not carbon dioxide, and it did not combine with caustic potash. The growth from the heart's blood of the same monkey grew abnormally fast, much faster than I have ever seen plague grow, but when it was injected into the peritoneum of a mouse, the peritoneal fluid and organs contained bacilli, apparently those of plague. One other micro-organism was found in the peritoneum of a monkey which was killed by subcutaneous injection of plague. This was a diplo-coccus, which also was capsulated. I have not done any further experiments with this; it only happened recently, and I know nothing further about it.

26,342. Then I believe you have made experiments on the effect of various external conditions upon the growth of the bacillus?—Yes, I have. I have tried the effect of light, darkness, and temperature on the growth of plague. I find that plague grows fastest in the incubator at a temperature of about 37° C. It grows faster at 37° C. than it does in the ordinary room temperature, taking that to be between 24° C. and 27° C. I tried to see if there was any difference in the rate of growth in darkness and in ordinary diffused light, but I could not satisfy myself that there was. I also tried experiments as to the effect of exposure of plague to direct sunlight. I have done a good many experiments on that, and the result has been very constant in one respect: I have never been able to recover from culture tubes living plague, either from broth or from agar, which have been exposed to sunlight for four hours. I have done several experiments, and exposed it for shorter periods. I have twice recovered it after three hours. In one experiment I did, a broth culture was exposed to the sun for three hours. A sub-culture was then made on agar. Nothing was seen for five days, when a few very minute colonies were noticed, microscopically very much resembling plague. After eleven days there was very little growth. The effect of sunning it for three hours apparently was that it retarded the growth. This culture was emulsified and injected into the peritoneum of a mouse, which died two days afterwards, with numerous bacilli, apparently plague, in the spleen, liver, and blood. Then I repeated the above experiment with an agar tube, and there again I recovered plague after it had been exposed for three hours to sunlight. I also did some experiments by exposing to sunlight plague infected pieces of calico. In one experiment I took six square pieces of thin calico, steeped them in plague culture, and exposed them for three hours to strong sunlight in sterilized Petri dishes in the following manner:—One was covered with one layer of calico, one was covered with two layers of calico, one was covered with three layers of calico, one was covered with four layers of calico, one was covered with five layers of calico, and one was covered with six layers of calico, and exposed for three hours to sunlight. Each piece of calico was then placed in broth for several days. No growth took place, even from the one which had been covered by six layers of calico. I did another sunning experiment with flannel. I took five square pieces of flannel; they were well washed and sterilized, soaked in plague culture, and exposed for 3½ hours to sunlight in a Petri dish with the cover off. One was covered with one layer of flannel, one with two layers, one with three layers, one with four layers, and one with five layers of flannel. When removed and placed in bouillon, typical plague growths resulted, but No. 1 only showed growth after four days. Another experiment was done with the hem of an ordinary calico pocket handkerchief. It was soaked for three days in plague culture; it was then exposed for three hours to strong sunlight in a Petri dish. It was then placed in bouillon. It showed no growth for nearly a week, but then grew vigorously. That rather confirms the previous experiment as to the retardation of growth by exposure to sunlight. Another experiment was done with cotton wool. Ordinary cotton wool was twisted so as form a thickness of ordinary knitting wool. This was soaked in a plague culture, removed to a Petri dish, and exposed to strong sunlight for three hours. When removed to bouillon it showed vigorous growth within 24 hours.

26,343. Have you, in any of your experiments, found sunlight to completely kill the bacillus?—I have never grown it after four hours' exposure.

26,344. What have you to say with regard to desiccation?—Pieces of calico were thoroughly soaked in a plague culture, and then removed to sterilized Petri dishes, and allowed to dry at the ordinary temperature of the room, and in diffused light. Cultures were obtained from a piece of calico for the first four days, and then the experiment was interrupted for six days. On the 11th day no cultures could be obtained. Apparently for the first four days plague can be recovered. I know nothing between four and 11 days; on the 11th day I could not recover it. I also tried another way, by introducing calcium chloride into the same Petri dish. I put sterilized cotton fabric soaked in plague emulsion into a Petri dish in which calcium chloride was placed. At the end of 18 hours the cotton was placed in broth. No growth resulted. Of course, the calico was very dry indeed.

26,345. What has been the general result of your desiccation experiments?—That exposing a plague culture for at least four days to ordinary drying does not kill plague. Of course, there is no reason why it should. It depends upon the amount of broth you use. Apparently it takes four days for a piece of cotton soaked in broth to become so dry that plague will not grow upon it, yet if it is dried very rapidly with calcium chloride, the period of time is much shorter.

26,346. After absolute dryness, how long will the plague bacillus live?—I could not obtain it after 18 hours in one case: I am still experimenting on that subject.

26,347. I believe you have also tested the resistance of plague to various disinfectants?—I have done a few experiments with regard to the resistance of plague to disinfectants. In one experiment I did, an emulsion of plague was made, and of this ½ c.c. was added to the following tubes:—1 in 1,000, 1 in 2,000, 1 in 5,000, 1 in 10,000 and 1 in 20,000 perchloride of mercury. After half-an-hour a loop-full from the above tubes was planted in broth for 12 hours, in order, as far as possible, to eliminate the admixture of the bacillus with the disinfectant. Then sub-cultures were made on agar from each broth tube. I did this with plague, and also with a coccus, which I have found very resistant in other experiments. I found that I could grow the coccus from the tube of 1 in 20,000, but I could not grow plague from any of them. Plague did not grow after being exposed to perchloride of mercury 1 in 20,000 for half-an-hour.

26,348. Did you observe any characteristic odour in the cultivations from broth?—Yes; I think that plague cultures have a very characteristic smell. I think you can smell it in agar, but you can smell it best in broth. I once distilled a broth culture, and the distillate smelt very strongly indeed. It was the same smell, but in a more concentrated form.

26,349. Can you describe the smell?—It is very difficult to describe a smell. It is a very unpleasant smell; I do not think I can describe it any better than that.

26,350. Have you made any experiments on the disinfection of houses?—I went to one house in the C. district in Bombay. Scrapings from the floor and wall were collected before and after disinfection by the disinfecting gang. I was informed that the disinfectant used was perchloride of mercury in the strength of about 1 in 500. A few c.c. of broth were added to the earth samples, and the pledgets of cotton wool which had been used to collect samples of the wall were dropped into broth. The samples were collected immediately after disinfection, while the floor and wall were still wet. Consequently a good deal of the disinfectant was present in the samples. They were plated in Petri dishes. After 24 hours there was no appreciable difference in the number of colonies from the wall before and after disinfection. I do not know what the explanation is. Perhaps it is that the wall is greasy, and the disinfectant does not remain there very long;

Lieut. H. J. Walton, M.B., F.R.C.S. I.M.S.

21 Mar. 1899.

but that is how it was. But in the floor samples there was a difference. The method of disinfection which they adopted was, first to enter the room and squirt vigorously on the floor; then they squirted the walls and the roof, and the disinfectant ran down on to the floor, so that the floor was a kind of pond at the end of the process. I found that the floor samples, which had been taken before disinfection, grew very vigorously, but no growth occurred for the first 24 hours in floor samples which had been taken after disinfection but after three days there was a growth in all of the samples taken, but not of plague. I was not looking for plague; I was trying to find if the process destroyed the ordinary organisms.

26,351. In none of these cases did you identify the plague bacillus, I suppose?—No. There was another experiment which I did, namely, trying the effect of carbolic acid on a wall. A wet sterile cotton wool plug was wiped on the wall and a broth tube inoculated with it. Then five per cent. carbolic acid was squirted over a portion of the wall, which was covered with a Petri dish to prevent air organisms getting there, and left for 10 minutes. Then a second broth tube was inoculated in the same way as the first had been. After 24 hours there was abundant growth in the control tube, and after 48 hours the second tube showed colonies of a spore-bearing bacillus. The result was not very satisfactory.

26,352. It was not very much in favour of carbolic acid?—No.

26,353. What has been your experience with regard to the treatment of plague cases with anti-toxic serum?—I have only treated 15 cases altogether.

26,354. With what serum?—With Roux' serum, from horse No. 31 and horse No. 21. One case I treated at Bangalore. It was a hopeless case. The girl had extensive broncho-pneumonia and was very weak when she came in. She had 28 c.c. of serum and died. Most of my cases were done at the Modi Khana Hospital in Bombay. Another case that I treated, and which I wish to be considered in a separate category, was one at the Port Trust Hospital here. The reason I put it into a separate category is that I had no control. In the Modi Khana cases I had controls to all. This case, in the Port Trust Hospital, is the man I spoke about before, in whose sputum I saw what I believed to be plague bacilli. He had 40 c.c. of the serum injected into his veins and recovered.

26,355. Within what time had he the 40 c.c.?—He had that at once. Then at the Modi Khana Hospital I treated 13 cases with 13 controls.* Alternate cases were taken. I had no voice in the selection of the cases. The doctor in charge of the hospital gave me a case as it came in and said "So-and-so is your control"—that was, as a rule, the next man who came in. I treated 13 cases, of whom 10 died, being a mortality of 76·9 per cent. All the 13 controls died. This was about six weeks ago, when plague was exceedingly virulent. The mortality of the cases treated was 76·9 per cent., and the mortality of the controls was 100 per cent., but of course the numbers are so small that you cannot draw any positive conclusions from those experiments.

26,356. Have you made any experiments on the effect of the serum on the pulse?—I could detect no constant effect of the serum on the pulse, respiration, temperature or symptoms.

26,357. Was the duration of life longer or shorter in the case of those treated with the serum than in the case of the controls?—At first I rather thought myself that it was somewhat longer, but I took the trouble to count the number of days that the fatal cases lived, both those treated with the serum and controls, and I found there was no difference.

26,358. What were the separate doses and total amounts given of the serum?—The most I gave was 220 c.c. to a man who recovered.

26,359. In what time?—He received on an average about 60 c.c. a day.

26,360. For about four days?—Yes.

26,361. What was the largest amount you gave at one time?—The most I ever gave at a time was 40 c.c.

26,362. This was to the man who had 220 c.c. altogether?—Yes, he had 40 c.c. at a time, but so had most of my cases.

26,363. What were the other totals?—They varied between 40 c.c. and 220 c.c.

26,364. I suppose they often died before they had received much serum?—Yes. Very often I would give a man one injection and when I went round in the evening he was dead, so that he never received more than 40 c.c.

26,365. Did you notice much local irritation produced by the larger injections?—No; I have never noticed the slightest local irritation. There is one point about these cases which I should like to mention, and that is with regard to the frequency of lung symptoms. By lung symptoms I mean symptoms of broncho-pneumonia, which seem to be very common in the present epidemic. I find that of the 13 cases I treated, eight had lung symptoms.

26,366. What about the controls?—I cannot tell you about them, but I presume they would come out about the same, because they were not picked in any way. Two of the cases which recovered had lung symptoms, and there was also that case at the Port Trust Hospital which had lung symptoms and recovered.

26,367. On the whole these cases were very unfavourable for any treatment, were they not?—Yes.

26,368. Have you anything else to add?—I have nothing else to say, except with regard to the mortality at the Modi Khana Hospital, among cases treated with Roux' serum. Lieutenant Douglas and I were working together there. We added our cases up and found that the percentage mortality was 81·48, and that in a similar number of controls the percentage mortality was 85·18. But the total number of cases was only 27, so that I do not think you can draw any conclusions in favour of Roux' serum from that.

26,369. (*Prof. Wright.*) You do not think the efficacy of the disinfection of a house can be properly tested by merely comparing the number of bacteria before and after disinfection?—That seems to me to be the only way available. Of course the fact that you cannot find plague is no evidence that a house has been satisfactorily disinfected, because under the most favourable circumstances it is very difficult to recover plague bacilli.

26,370. When you find that the number of bacteria is not reduced by the disinfection process, does it always follow that the house has not been completely disinfected against plague?—No, I do not think so at all. I think there may be resistant micro-organisms and spore-bearing micro-organisms which would not be destroyed by a process which would kill plague.

26,371. You think the disinfection of a house would be adequate if you found that all the bacteria which survived had more resisting power than the plague bacilli?—Yes, I think it might be adequate.

* *See* App. No. LXXXI. in this Volume.

(Witness withdrew.)

Lieut W. G. Liston, M.B., I.M.S.

Lieut. W. G. Liston, M.B., I.M.S., called and examined.

26,372. (*The President.*) You are a member of the Indian Medical Service, and have been on special duty with the Indian Plague Commission?—Yes.

26,373. You have been making special researches in connection with plague?—Yes.

26,374. When did you commence them?—On the 5th December.

26,375. I believe you have endeavoured to determine the sterility or otherwise of Haffkine's fluid?—Yes, I have examined twelve bottles. To test each bottle, two agar tubes were used. The first of these was inoculated with a small quantity of undiluted vaccine. The second was inoculated with exactly the same quantity of vaccine as the previous tube, but this time diluted with four volumes of sterile broth. In all twelve bottles were examined. The date on which the vaccine was prepared was not noted on the bottles. Care was taken to choose only those bottles that had the sealing wax on the corks intact, otherwise the bottles were chosen at random from samples of almost every brew which M. Haffkine had in his laboratory at the time, and which he had kindly sent for examination. Of these twelve bottles nine were found to be sterile, viz., brews

Nos. 9029, 6174, 3927, 6161, 4552, 6112, 4739, 6053, 3993. Three were found to contain micro-organisms, viz., brews Nos. 6151, 3895, and 3911.

No. 6151. Only a single colony grew in the undiluted tube.

No. 3895. Copious growth in undiluted tube of an oval bacillus non-motile, and forming small transparent colonies; similar growth in the diluted tube.

No. 3911. Thirty to forty colonies in the undiluted tube. Nine small colonies in the diluted tube.

26,376. In any of these cases were there any organisms which at all resembled the plague organisms?—No.

26,377. Do you know whether any of the detected organisms are pathogenic or not?—No.

26,378. You have made experiments on the relative toxicity of the supernatant fluid and sediment of Haffkine's fluid?—Yes, and also protectively afterwards. In this experiment six guinea-pigs were used, three receiving doses of the supernatant fluid and three doses of the sediment. The brews used in the experiment were the following:—

Brew. No. 5344, dose 6¼ c.c.
" " 5338, " 6½ c.c.
" " 5344, " 6¼ c.c.
" " 5315, " 6¼ c.c.
" " 5975, " 6¼ c.c.
" " 4422, " 2½ c.c.
" " 4414, " 7½ c.c.

These bottles had been standing in the laboratory for some time, and their contents had separated into two portions, a supernatant brown clear fluid and a muddy greyish brown deposit. The bottles were carefully opened and the supernatant fluid drawn off with a sterile pipette. The sediment remaining was freed, as far as possible, of excess of fluid by means of the pipette; a thick emulsion was thus obtained. The supernatant fluids from all the brews were mixed in one flask and the sediments in another. The details of the experiment are given in the following table:—

TABLE I.

DETERMINATION of TOXICITY of the SEDIMENT and SUPERNATANT FLUID of HAFFKINE'S PROPHYLACTIC.

Number of Guinea-pig.	Component of the Prophylactic which was injected.	Dose of the foregoing Component which was injected.	Result.
Number 1 -	Supernatant fluid - -	1 c.c. per 100 grammes of guinea-pig's body weight.	Survived.
" 2 -	"	2 c.c. per 100 grammes of guinea-pig's body weight.	Died 5 days after inoculation. (*Note* 1.)
" 3 -	"	4 c.c. per 100 grammes of guinea-pig's body weight.	Died 4 days after inoculation. (*Note* 1.)
" 4 -	Sediment -	½ c.c. per 100 grammes of guinea-pig's body weight.	Survived.
" 5 -	"	1 c.c. per 100 grammes of guinea pig's body weight.	Survived.
" 6 -	"	2 c.c. per 100 grammes of guinea-pig's body weight.	Survived.

Note 1.—No micro-organisms could be detected after death in the bodies of these animals.

26,379. I understand that anything above 2 c.c. of the supernatant fluid killed them?—Yes, any dose above 1 c.c.

26,380. What is the minimum lethal dose of the supernatant fluid?—2 c.c.

26,381. The doses you used of the sediment did not exceed 2 c.c.?—No.

26,382. You had only one experiment in which you administered the supernatant liquid in the lethal dose of 2 c.c.?—Yes, we used larger doses of the non-carbolized supernatant fluid, and compared its toxicity with that of the nutrient broth in which the bacillus is grown. A series of guinea-pigs were inoculated with doses of 5, 10, 20, 30 c.c. of broth and non-carbolized supernatant fluid, respectively, eight guinea-pigs being used in all. These guinea-pigs were all inoculated on the 15th March. On the 19th all the guinea-pigs were well except one, which received 10 c.c. supernatant fluid, which died on the 18th, and was found to have in its liver and spleen a few groups of cocci, which stained by Gram's method, so that it is possible that this was an accidental death.

26,383. And could not have been due to the inoculation?—That is so.

26,384. It must have been poisoned in some other way?—Yes. The details of the series of guinea-pigs are as follows:—

TABLE II.

ESTIMATION of the RELATIVE TOXICITY of (*a*) the ORIGINAL NUTRIENT MEDIUM which is EMPLOYED in the PREPARATION of M. HAFFKINE'S PROPHYLACTIC; and (*b*) of the same NUTRIENT MEDIUM (un-carbolized but heated to 65° C. and filtered), after it has served as a CULTIVATION MEDIUM for the PLAGUE BACILLI. —(*Note* 1.)

Number of Guinea-pig. *Note* 2.	Kind of Broth, and Amount of same which was injected.	Temperature of Guinea-pig on the Day after Inoculation.	Final Result, One Week after Inoculation.
Number 1 -	Haffkine's nutrient medium, 30 c.c.	103° F.	Quite well.
" 2 -	Haffkine's nutrient medium, 20 c.c.	102·2° F.	" "
" 3 -	Haffkine's nutrient medium, 10 c.c.	102·8° F.	" "
" 4 -	Haffkine's nutrient medium, 5 c.c.	102° F.	" "
" 5 -	Filtrate from plague culture grown in above medium, 30 c.c.	102·6° F.	Quite well, except for fact that there is a small patch of necrosis at site of inoculation.
" 6 -	Filtrate from plague culture grown in above medium, 20 c.c.	102·4° F.	Quite well, except for small patch of necrosis at site of inoculation.
" 7 -	Filtrate from plague culture grown in above medium, 10 c.c.	96·8° F.	Died, probably of intercurrent infection (*vide* text *supra*) 3 days after inoculation.
" 8 -	Filtrate from plague culture grown in above medium, 5 c.c.	103·4° F.	Quite well.

Note 1.—M. Haffkine kindly furnished the material which was employed in this series of experiments. The material consisted of (*a*) a large flask of freshly prepared nutrient medium, such as he employs as a cultivation medium for plague bacilli in the preparation of his plague-vaccine; (*b*) a large flask of the above nutrient medium which had served as a cultivation medium for the plague bacilli, and which had just been heated to 65° C. with a view to converting it into plague-vaccine.

Note 2.—The guinea-pigs which were employed for this experiment were afterwards (*vide* Table VI. *infra*) submitted to a test with a view to ascertaining whether they had acquired any immunity.

It would, therefore, appear that the toxic element of the supernatant fluid of Haffkine's vaccine for guinea-pigs is, probably, the contained carbolic acid.

26,385. You have made some experiments with regard to the protective power of the fluid and of the sediment?—Yes, I made the following experiment. The guinea-pigs which were used were those which survived the experiment reported in Table I. above, and one control guinea-pig. There were three guinea-pigs which survived the doses of sediment and one which survived the dose of supernatant fluid.

Lieut. W. G. Liston, M.B., I.M.S.

21 Mar. 1899.

TABLE III.

DETERMINATION of the respective PROTECTIVE POWER of the SEDIMENT and SUPERNATANT FLUID of HAFFKINE'S PROPHYLACTIC.

Number of Guinea-pig.	The Guinea-pig had previously been injected with	Interval that had elapsed since the previous Injection.	Amount of Plague culture which was now injected.	Result.	Remarks.
No. 1 * *Note* 1 (control.)	Nil	-	½ agar culture	Died 6 days after	Plague bacilli; abundant small nodule in spleen.
No. 2 (No. 1 of Table I. *supra*)	Haffkine's supernatant fluid, 1 c.c. per 100 grms. of body weight.	8 days	Ditto	Died 24 hours after.	No local reaction or buboes; no nodules in organs; abundant plague bacilli.
No. 3 (No. 4 of Table I. *supra*)	Haffkine's sediment, ½ c.c. per 100 grms. of body weight.	Ditto	Ditto	Died 9 days after.	Marked local reaction, nodules in lungs.
No. 4 (No. 5 of Table I. *supra*)	Haffkine's sediment, 1 c.c. per 100 grms. of body weight.	Ditto	Ditto	Died 5 days after	Some local reaction.
No. 5 (No. 6 of Table I. *supra*)	Haffkine's sediment, 2 c.c. per 100 grms. of body weight.	Ditto	Ditto	Died 5 days after	Some local reaction.

* *Note* 1.—It is to be noted that this guinea-pig may have been, to some extent, immune against plague, inasmuch as he was an animal which had survived an epidemic of plague which had occurred among the guinea-pigs in another laboratory.

26,386. You have further made some experiments on the longevity of the bacillus in grain and gunny bags?—I made the following series of experiments:—

I took two pieces of gunny bag and two samples of wheat. I placed each of these in a separate test tube and sterilized them and labelled them respectively tubes 1, 2, 3, and 4. I then thoroughly moistened the contents of these four tubes with a broth emulsion of a plague culture on agar. The contents of the tubes were then allowed to become air dry by placing them in an incubator.

Two days afterwards I introduced some sterile broth into tube 1 (one of the tubes which contained grain), and shook it up after allowing it to remain in contact with the grain for a little time. A portion of the washings of grain which were thus obtained were introduced into an agar tube. The rest of the washings were injected into *guinea-pig No.* 1. This guinea-pig remained well.

At same time some of the grain from tube No. 2 was introduced into a tube of sterile broth.

At same time a piece of gunny bag from tube No. 3 was treated in the same way as the contents of tube No. 1. A portion of the washings of the gunny bag was introduced into an agar tube. The rest of the washings were injected into *guinea-pig No.* 2. The guinea-pig remained well.

At the same time a portion of gunny bag from tube No. 4 was introduced into a tube of sterile broth.

Two days after I had performed the above operations, both of the agar tubes (*i.e.* the agar tubes which had been inoculated respectively with the washings of the grain and with the washings of the gunny bag) showed three or four colonies of bacilli, which had the microscopical appearance of plague bacilli. At the same time both the broth tubes (*i.e.* the broth tubes which had been inoculated respectively with a portion of dried grain from tube No. 2 with a portion of dried gunny bag from tube No. 4) showed a growth.

I inoculated 1 c.c. of the broth, into which the dried grain had been introduced into *guinea-pig No.* 3. Further, I inoculated 1 c.c. of the broth, into which the dried gunny bag had been introduced into *guinea-pig No.* 4. Two days after the *guinea-pig No.* 4 *died.* Plague bacilli were recovered from its spleen and liver. On the next day, *guinea-pig No.* 3 *died.* Plague bacilli were recovered from spleen, liver, and peritoneal fluid.

In view of the above results a further portion of the grain and a further portion of the gunny bag which had been infected with plague seven days previously were introduced into two further sterile broth tubes.

Two days after this 1 c.c. of the contents of each of these broth tubes was introduced respectively into *guinea-pigs* 5 *and* 6.

Guinea-pig No. 5 (*i.e.*, the guinea-pig into which the broth culture which was derived from the gunny bag was injected) died three days after he had been inoculated. There was evidence of considerable local reaction, but plague bacilli were recovered from spleen and liver.

Guinea-pig No. 6 (*i.e.*, the guinea-pig into which the broth culture which was derived from the grain was injected) showed slight local reaction three days after he had been inoculated. This guinea-pig developed no further symptoms.

In view of the result which was obtained with guinea-pig No. 5, a further portion of the gunny bag was planted out into sterile broth 12 days after it had been infected with plague.

This broth was cultivated for three days, 1 c.c. of the broth was then introduced into *guinea-pig No.* 7. The guinea-pig remained perfectly well.

It has thus been possible to recover the plague bacillus by continued inoculations from infected grain up to the third but not so late as the seventh day. In the case of the infected gunny bag it has been possible to recover the bacillus up to the seventh day, but not as late as the twelfth day after infection.

26,387. You made some experiments as to the growth of plague bacilli in an atmosphere of hydrogen?—Yes. The plague bacillus was grown in broth in an atmosphere of hydrogen gas. The growth was not rapid, and it did not differ much from the growth in broth exposed to air. In view of the fact that the plague bacillus appeared thus to be a facultative anaerobe an attempt was made to obtain the plague bacillus from earth floors of three infected houses by making, first, a cultivation in hydrogen and afterwards a cultivation in air.

Sources of the earth:—

I. Collected on 8th February 1899, from 25, Bori Street, one fatal case of plague had occurred in the house.

II. Collected on 8th February 1899, from hut in Victoria Bandar, fatal case of plague had occurred in the house on 8th February 1899.

III. Collected on 8th February 1899, from hut in Victoria Bandar, a plague case was sent to hospital from the hut on 8th February 1899.

Small quantities of the earth were mixed with broth and a portion of this broth (about ½ c.c.) was added to sterile broth. Hydrogen gas was then passed through the broth and the tubes sealed. A control broth culture of pure plague was at the same time made in hydrogen, and when this tube showed a distinct growth (36 hours later) the tubes in which the earth organisms were being cultivated were planted out in three dilutions on agar plates. These were examined from time to time during four days for any colonies resembling plague; any such were examined microscopically always with negative results. A similar series of experiments were done with the same samples of earth which had been and were artificially infected with plague bacilli. Not even under these circumstances could the plague bacillus be isolated from the earth by this method.

26,388. The whole series has been purely negative? Yes.

26,389. You have endeavoured to find the bacillus in the urine of plague patients?—Yes. The urine of 50 plague patients was examined bacteriologically, and the plague bacillus was isolated in two cases only. The

ıethod of collecting the urine is open to some riticism. It was accomplished in the following ıanner:—The patient was made to pass water, and fter a small quantity had been passed, a little was ollected in a sterile tube. This urine was allowed to tand for a few hours till the mucus, &c. sank to the ottom of the tube. With a sterile pipette a small uantity (about ½ c.c.) of the urine from the surface f the deposit at the bottom of the tube was with-rawn and planted on agar. In only one case was he urine thus obtained found to be sterile. Almost lways a rapidly growing micro-coccus was found.)ccasionally other bacteria were found. Any colonies vhich at all resembled plague colonies were examined, ınd when a bacillus microscopically resembling plague vas found it was isolated and grown in pure culture. Some of the pure culture then was inoculated into a rat, ınd the micro-organisms were again recovered from the lead animal. In only two cases was the plague bacillus hus found, viz., in cases Nos. 65 and 280, Mahratta Hospital. In the latter case, 280, a sample of the blood obtained from the finger at the same time as the ırine gave a very abundant growth of the plague bacillus.

26,390. Can you give us some information as to the stage of illness when it was taken, and also how long before death?—Yes.

Case No. 65 was admitted into the Mahratta Hospital on 6th of January with right axillary bubo. His urine was obtained on the 12th, five and a half hours before death.

Case No. 280 was admitted into the Mahratta Hospital on 18th January 1899, with right femoral bubo. His urine was obtained on the 19th, four hours before death. The blood from the finger, taken at the same time, gave an abundant growth of plague.

26,391. What was the result of your experiments with regard to fæces?—I have tried four cases by plate cultivation and by successive strokes on agar tubes, three tubes being used; but in no case was I able to get the plague bacillus. The great difficulty was the rapidly growing contaminating micro-organisms.

26,392. Perhaps, in this instance, you will also state the period of illness?—Yes.

Case 226.—Bubo left inguinal. Admitted 16th January 1899; sample taken on 17th; died on 18th.

Case 284.—Right central bubo. Admitted 18th; sample taken on 18th; died on 19th.

Case 437.—Left axillary bubo. Admitted 24th January; sample taken on 25th. This patient recovered.

Case 530.—Left femoral bubo. Admitted 27th January; sample taken on 28th. Patient died on 30th January 1899.

26,393. You have examined the sweat in several cases?—Yes, and I never discovered plague bacillus.

26,394. Were they fatal cases?—I could not say.

26,395. Can you tell us the period of illness?—I am afraid I cannot give you that information.

26,396. You have also examined buboes, I think?—Yes. One bubo was examined by hypodermic needle; a small quantity of lymph withdrawn and planted on agar. This patient was recovering at the time of operation; his temperature being normal. Several colonies of staphylo-coccus albus developed, and a small diplococcus, but no plague bacilli. Another bubo was examined when opened, the patient still suffering from fever, and died some days later. A pure growth of plague bacillus was obtained from this case.

26,397. Was the bubo opened during the time of operation?—It was being opened. The discharge from another bubo, which had been opened some days, was examined, but no plague bacilli were found.

26,398. Have you ever found bacilli in a bubo?—Yes; on the one occasion which I have mentioned.

26,399. You have also examined the blood?—Yes. I have examined the blood from the finger on several occasions. I have no notes of the exact number of patients which I examined, but I frequently found the plague bacillus in the blood. It was from this source that we got nearly all our plague cultures.

26,400. Can you tell us the longest period before death when you found the bacillus?—The longest period that I ever found the plague bacillus in the blood before death was 51 hours.

26,401. I suppose you also found it at the moment of death?—Yes. I examined one case about one hour after death, and found the bacilli abundant in the veins.

26,402. What is your opinion as to the value of microscopic examination alone in detecting the plague bacillus?—It cannot be relied upon at all alone. The detection of plague by the microscope alone is exceedingly hard, indeed impossible. I have seen many bacteria, which, microscopically, look very like plague, and which, on more critical examination, as by rate of growth, character of colonies, and inoculation experiments on animals, have proved not to be plague. The size of the plague bacillus varies considerably, both in different growths and as regards the individuals in the same growth. A quickly growing plague bacillus on artificial media is, as a rule, a small bacillus, while a larger variety is a more slowly growing one. The individual members of a growth frequently vary from an almost coccus-like form to long thread-like individuals. Similar involution forms may be found in animals, but very rarely, the individuals are much more uniform in size, and, as a rule, stouter than the original growth on agar; bi-polar staining, too, is much better marked.

26,403. Have you any observation with regard to the persistence of plague after the death of animals?—With regard to the persistence of the plague bacillus after death, it is difficult to make sure that an animal has died of plague when decomposition has set in. Several such animals have been examined, and frequently a large thick spore-bearing bacillus has been found in all the organs and in the blood which apparently obscures or in some way destroys the plague bacilli. With a view to ascertaining whether any change occurred in an animal which was known originally to contain many plague bacilli the following experiment was made. A guinea-pig, which died of plague, was first examined shortly after death. Many plague bacilli were found in all the organs, bubo, and heart's blood. Other examinations were made two hours, six hours, and 26 hours after death, with the result that, despite the fact of the presence of many contaminating bacteria, the plague bacilli were abundantly evident even after 26 hours.

26,404. Were the bacilli dead or living?—I did not make cultivations.

26,405. What media have you used to cultivate the plague bacillus?—Various media were tried for the cultivation of the plague bacillus. An almost neutral agar or broth was found most suitable for ordinary use. The bacillus grew well, too, on glycerinated agar, but not well on glucose agar. Boiled white of egg did not make a good media, although the bacillus did grow slowly, forming peculiar involution forms with squarer ends than usual and many long forms. Sterile plantain was also tried, but the growth was not good or characteristic. The addition of varying proportions of anti-plague serum (Roux) to bouillon was tried. Those tubes in which the largest proportion of serum was present seemed to grow slightly faster. The serum of convalescent patients had no restraining influence on the growth of plague. Roux' serum on the surface of agar formed an excellent medium in which to grow the plague bacillus.

26,406. What do you infer from that fact with regard to the bactericidal property?—I infer that Roux' serum and the serum of convalescent patients outside the body has no bactericidal properties on the plague bacillus.

26,407. Have you paid some attention to the pathological appearances in the several animals on which you made experiments?—Yes, on rats. Little, generally, could be learnt as to whether a rat had died of plague by external examination. Buboes, although found on one or two occasions, were very rare. Inguinal axillary and parotid buboes were seen. As a rule, no indications were evident to point to the path of infection. The liver and spleen are always enlarged, soft, and friable. Frequently, no enlarged lymph glands in any situation could be detected. Microscopically, plague bacilli could be found in the heart's blood, often very few in number, but abundantly found in the liver, and particularly in the spleen. Pure cultures of plague bacillus were easily obtained from these situations. Buboes in which suppuration had taken place very rarely gave a growth of plague.

Lieut. W. G. Liston, M.B., I.M.S.

21 Mar. 1899.

26,408. They did sometimes?—A cultivation was obtained on one occasion.

26,409. Usually, you did not get it?—That holds true when suppuration has occurred. The *post-mortem* appearances found in guinea-pigs varied much more than in rats. Certain guinea-pigs showed a considerable degree of resistance. This resistance was seen in three different sets of animals. It was seen (1) in animals which had been vaccinated by the sediment in Haffkine's prophylactic; (2) in animals which had been injected with Roux' serum; (3) in animals which had survived an epidemic of plague which broke out among the animals kept in a shed in M. Haffkine's laboratory compound.

A non-resistant guinea-pig died of plague in from two to five days after hypodermic inoculation. There was, as a rule, little reaction at the seat of inoculation. A small bubo was generally found on the same side as the point of inoculation. The liver and spleen were enlarged, soft, and friable; hæmorrhages were frequently found, subcutaneously, near the seat of inoculation, and subperitoneally; also and perhaps most frequently around the kidneys. Frequently, also, some subserous punctiform hæmorrhages were found along the alimentary tract. Plague bacilli were abundantly found in liver and spleen and bubo, also at the seat of inoculation, less numerous in heart's blood. Peritonitis was found on two or three occasions showing microscopically an abundant and pure growth of plague.

A more resistant guinea-pig took longer to die, often more than five days. There was marked reaction at the seat of inoculation, a hard mass being felt which might cover an area of from one to two square inches. Buboes were larger, often more numerous than in rats. Suppuration was usual at seat of inoculation, occasionally also in the buboes. The spleen was enlarged and contained small tubercular greyish yellow hard nodules. Bacilli were abundantly found in these nodules, particularly at the periphery of the nodules for the centre of the nodule was degenerated or necrosed and did not stain well. Although the pulp of the spleen contained bacilli, their numbers were not so great as in the nodules. This was evident both by microscopical examination and by cultures on agar, a more abundant growth being obtained from a nodule than from the spleen pulp. The nodules varied in size from small just visible points giving a mottled look to the spleen (under these circumstances they were very numerous) to larger nodules from one-sixteenth to one-eighth inch in diameter, the nodules were then much fewer. Still more resistant guinea-pigs (and when I speak of these I refer particularly to those which received from one to two c.c. of Roux' serum at the time of inoculation with plague) showed very marked reaction at the seat of inoculation, which was generally the side of the abdominal wall. The infiltrated area often extended across the middle line and buboes were found in both axillæ and both groins. The buboes were largest on the side of inoculation; pure cultures of plague were obtained from all the buboes. The lungs showed small hard fibrous looking nodules which varied in size from one-eighth to one-quarter inch in diameter. The portions of lung tissue not occupied by the nodules were dark coloured and resembled the appearance seen in hypostatic pneumonia. Very little healthy lung tissue was left. In one case there was pleural effusion (hæmorrhagic) on one side. The spleen and liver were not much enlarged if at all, no nodules were noted in the spleen. Growths were abundantly obtained from the buboes and nodules in the lung, but not from the rest of the lung tissue. No growth was obtained from the liver, and on two occasions one colony from the spleen only. Microscopic specimens showed plague bacilli abundant in buboes and in the nodules in the lungs, but not in the lung tissue or other parts. The arrangement of the bacilli into little clumps in the lungs and spleen was very marked. Agar growths from these guinea-pigs gave many very long filamentous forms. Phagocytosis was frequently noted. On one occasion it was very marked in a guinea-pig, which had previously been vaccinated against plague, and which some time after received a large dose of living plague. In another case it was noted in the peritoneal exudation of a guinea-pig which had died of plague in the epidemic which broke out among the animals at M. Haffkine's laboratory. Another case of interesting phagocytosis was seen in the liver of a human fœtus. The mother aborted and died. An hour later, a pure growth of plague bacilli was obtained from some blood which was drawn from the basilic vein after death. A mixed growth containing plague bacilli was obtained from the vaginal discharge. The umbilical cord, liver, and spleen of the fœtus was examined microscopically; only in the liver were any plague bacilli seen, and these were all found phagocytosed in large mononuclear cells. Unfortunately no growths were made from the organs of the fœtus, as it had been placed in some rum to preserve it before it reached me.

26,410. (*Dr. Ruffer.*) Did you sterilise grain before you added the plague culture?—Yes.

26,411. Did you make any experiments on non-sterilised grain?—I am making them now. I have not finished.

26,412. How do you find the presence of bacilli in grain? Do you test it by cultures?—By placing the grain in broth and then planting out an agar and also examining the broth.

26,413. Do you test it in any other way?—I am making a second series of experiments. I am inoculating animals.

26,414. Have you had any results?—Not yet.

26,415. Have you been able to produce plague from the cultures obtained from the grain?—No.

26,416. In the case of gunny bags, how did you inoculate them; did you steep them in plague cultures?—No. I poured a few drops all over the surface of the gunny bags from a sterilized pipette.

26,417. Of the broth culture?—Yes.

26,418. It would contain more food than rat's urine, for instance?—Yes, and probably more bacilli also.

26,419. Did you test the presence of this bacillus in the gunny bags by inoculation?—I have not done so yet, I am doing that now.

26,420. So far as you have gone you have not been able to reproduce the disease from gunny bags?—No.

26,421. Did you test it by making plates from gunny bags?—No.

26,422. How do you test for the presence of the bacillus after 48 hours?—A portion of infected gunny bag was placed in the broth and any growth which formed was examined.

26,423. Did you examine it microscopically?—Yes; and then planted it on agar in a tube.

26,424. You found no plague bacilli?—That is so.

26,425. Did you ever inoculate the broth which you got from gunny bags afterwards?—No.

26,426. Did you ever find the plague bacillus in the blood of plague patients who recovered?—Never.

26,427. You said just now that you have been able to grow the plague bacillus on a sterilized plantain?—Yes.

26,428. Does it grow well on a sterilized plantain?—I did not find it grow well.

26,429. Does it grow?—Yes.

26,430. So that you can get the growth of plague by purely a vegetable medium?—Yes.

26,431. In the case where you found plague bacillus in an open bubo, had that been opened artificially, or had it burst?—It had been opened artificially.

26,432. (*Prof. Wright.*) Will you, with a view to further testing whether any toxine passes out from the plague bacilli into the nutrient medium, test the respective toxicity, firstly of your peptone broth, and secondly of the filtrate from a plague culture which has been grown in that peptone broth. Further, will you determine whether that filtrate becomes less toxic when it is heated to 60° or 100° C. respectively?—(Witness afterwards submitted the following statement):—

A peptonised broth was made and sterilised in the usual manner.

This was divided into two portions.

Portion 1 was placed on one side to be used to determine the toxicity of the culture medium.

Portion 2 was inoculated with plague and was cultivated for three weeks.

After that time the broth was filtered off from the bacilli, the filtrate was found to be sterile.

It was then divided into three portions, Portion A., Portion B., and Portion C.

Portion A. was employed for determining the toxicity of the unaltered filtrate.

Portion B. was heated to 60° C. for one hour in order determine the toxicity of the filtrate after heating 60°.

Portion C. was heated to 100° C. for five minutes in der to determine the toxicity of the boiled filtrate.

The result of the experiments which were made were follows :—

TABLE IV.

ELATIVE TOXICITY of PEPTONE BROTH and of the HEATED and UNHEATED FILTRATE from a PLAGUE CULTURE which had been GROWN on that MEDIUM for THREE WEEKS.

Number* of Guinea-pig.	Amount and kind of Fluid which was injected.	Result.
uinea-pig No. 1 -	Original peptone broth, 10 c.c.	Survived.
„ „ 2 -	Original peptone broth, 20 c.c.	do.
„ „ 3 -	Original peptone broth, 30 c.c.	do.
„ „ 4 -	Unheated filtrate from plague culture, 10 c.c.	do.
„ „ 5 -	Unheated filtrate from plague culture, 20 c.c.	Died in 24 hours.
„ „ 6 -	Unheated filtrate from plague culture, 30 c.c.	Died in 36 hours.
„ „ 7 -	Filtrate from plague culture heated to 60° C., 20 c.c.	Died in 30 hours.
„ „ 8 -	Filtrate from plague culture heated to 60° C., 30 c.c.	Died in 24 hours.
„ „ 9 -	Filtrate from plague culture heated to 100° C., 20 c.c.	Very ill 36 hours after. (*Note* 1.)
„ „ 10 -	Filtrate from plague culture heated to 100° C., 30 c.c.	Died in 24 hours.

Note 1.—No further report as to the result of the experiment as since been received.

* The guinea-pigs in the experiment varied between 350 and 400 grammes in weight.

A soluble toxine appears thus to be developed when he plague bacilli is cultivated in peptone broth.

Further, it would appear that the soluble toxine is naffected by heating to 60° for one hour and by heating to 100° C. for five minutes.

26,433. Will you kindly further make experiments to determine the respective toxicity of (*a*) normal horse serum, (*b*) Galeotti's anti-plague serum, and (*c*) Roux' anti-plague serum ?—Yes. (Witness afterwards submitted the following statement of results) :—

TABLE V.

RELATIVE TOXICITY of NORMAL HORSE SERUM, of ROUX' ANTI-PLAGUE SERUM, and of GALEOTTI'S ANTI-PLAGUE SERUM.

Number of Guinea-pig.	Amount and Kind of Serum injected.	Result.
Number 1 - -	Normal horse serum, 20 c.c.	Survived.
„ 2 - -	Normal horse serum, 30 c.c.	do.
„ 3 - -	Roux' anti-plague serum, 20 c.c.	do.
„ 4 -	Roux' anti-plague serum, 30 c.c.	do.
„ 5 - -	Galeotti's anti-plague serum, 20 c.c.	do.
„ 6 - -	Galeotti's anti-plague serum, 30 c.c.	do.

Nothing in the general condition of these animals suggested that there was any difference in toxicity between these various sera.

26,434. Further, will you kindly determine in the case of the guinea-pigs which you employed for the experiments which are tabulated in Table II., whether the injection of the filtrate (uncarbolized) from Mr. Haffkine's prophylactic confers on guinea-pigs any greater protection against plague than the original nutrient medium which he employs ?—Yes. (Witness afterwards submitted the following statement) :—

Lieut. W. G. Liston, M.B., I.M.S.

21 Mar. 1899.

TABLE VI.

RESPECTIVE IMMUNIZING POWER of HAFFKINE'S ORIGINAL NUTRIENT MEDIUM and of the FILTRATE (*i.e.*, of the FILTRATE obtained from a CULTURE of PLAGUE which had been GROWN in HAFFKINE'S NUTRIENT MEDIUM) from HAFFKINE'S PROPHYLACTIC.

Number of Guinea-pigs.	Amount and Kind of Fluid which had been previously injected.	Date of the Test Inoculation with living Plague-Bacilli.	Interval which elapsed between the previous Inoculation and the Test Inoculation.	Result.
No. 1 - (Control.)	Nil - - -	5.4.99.	- - -	Died in 24 hours.
No. 2 - (No. 1 of Table II.)	Haffkine's original nutrient medium, 30 c.c.	„	18 days -	Died in 2 days.
No. 3 - (No. 2 of Table II.)	Haffkine's original nutrient medium, 20 c.c.	„	„	Died in 4 days.
No. 4 - (No. 3 of Table II.)	Haffkine's original nutrient medium, 10 c.c.	„	„	Died in 1 day.
No. 5 - (No. 4 of Table II.)	Haffkine's original nutrient medium, 5 c.c.	„	„	„
No. 6 - (No. 5 of Table II.)	Uncarbolised filtrate from Haffkine's prophylactic, 30 c.c.	„	„	Died in 3 days.
No. 7 - (No. 6 of Table II.)	Uncarbolised filtrate from Haffkine's prophylactic, 20 c.c.	„	„	„
No. 8 - (No. 8 of Table II.)	Uncarbolised filtrate from Haffkine's prophylactic, 5 c.c.	„	„	Died in 1 day.

If we take the three guinea-pigs, Nos. 6, 7, and 8 (*vide* above table), who received the filtrate from Haffkine's prophylactic, and if we compare them with the three guinea-pigs, Nos. 2, 3, and 5, who received comparable quantities of Haffkine's original nutrient medium, and if we add up the number of days which these two sets of guinea-pigs survived after the plague inoculation, it will be obvious that the protection which we afforded by the original nutrient medium is neither less nor greater than the protection which was afforded by the filtrate from Haffkine's prophylactic.

26,434A. Will you kindly further make some experiments on disinfection with a view to determining the efficacy or otherwise of the methods of disinfection which are applied to plague houses in Bombay ? Further, in making experiments on the subject, will you take as your test of the efficacy of all these disinfection processes, not the presence, or, as the case may be, the absence, of the plague bacillus, after the completion of the disinfection (for you have no satisfactory means of ascertaining that presence or absence), nor yet the destruction or non-destruction of a certain number of non-pathogenic bacteria in those houses. But will you, instead of either of these tests, take as your test of the effectiveness of a disinfection process the destruction, or, as the case may be, the non-destruction of all bacteria, except such as may prove themselves to be more resistant to disinfectants than the plague bacillus ? — Yes. (Witness afterwards submitted the following statement) :—

EXPERIMENTS ON DISINFECTION.

Eight disinfected rooms were examined generally, as shortly after disinfection as permitted the drying of the antiseptic on the floors. All the houses examined had pucka floors, *i.e.*, cement or stone floors.

The disinfected houses were all in the Mandvi district, and had been disinfected with a solution of perchloride of mercury, supposed to be of the strength of 1 in 500.

Lieut. W. G. Liston, M.B., I.M.S.
21 Mar. 1899.

The method of obtaining the cultures was as follows:—

The cotton wool plug was removed with antiseptic precautions, from an empty sterile test-tube, the inner end of the plug was rubbed over a considerable area of the floor, about one square foot, some dust and dirt was thus collected on the wool plug, which was again inserted into the sterile tube. In the laboratory a portion of the soiled wool was introduced into two broth tubes. These were placed in the incubator. Of the eight samples of dirt examined by this method one was found sterile. Three others were sterile except for the presence of a mycelial fungus. The specimens from the four other floors gave bacterial growths; these were planted out on agar plates, and the various bacilli found were isolated and grown in broth. In all, four varieties of bacteria were found. These were one micro-coccus, and three species of bacilli. The resistance of each of these bacteria was tested by an exposure for 15 minutes to the following dilutions of perchoride of mercury solution. The resistance was compared with the resistance of the plague bacillus when exposed for the same time to the same dilutions of perchloride solution.

The strengths of perchloride of mercury solutions were—

1 in 1,000.
1 in 2,000.
1 in 5,000.
1 in 10,000.
1 in 20,000.

It was found that in all cases the surviving organisms of the disinfected floors were less readily killed than the plague bacillus when tested by the above solutions.

The method of testing the resistance of the bacteria was as follows:—

All the bacteria were obtained in pure culture in broth. By a capillary pipette, a small quantity of the broth growth was placed in the sterile perchloride solutions of the above-mentioned strengths, and left for 15 minutes. After that time, with another sterile pipette, a small quantity was withdrawn from the bottom of the perchloride solution where the broth growth had sunk as a flocculent precipitate, and this was placed in a fresh broth tube.

The bacteria which were found survived 15 minutes' exposure in all dilutions of perchloride, even 1 in 1,000, except one bacillus, a small thin bacillus, producing yellow pigments. This last only survived a strength less than 1 in 2,000. Plague bacilli tested in a similar manner never survived 15 minutes' exposure to a strength of 1 in 5,000. In one series of experiments the plague bacillus did not survive exposure for 15 minutes to a solution of 1 in 10,000. It would thus appear that the bacteria which were obtained from these disinfected floors were in all cases more resistant to the action of perchloride than the plague bacillus.

26,434B. Will you further endeavour to ascertain whether the plague bacillus can, when it has been added to unsterilized earth, be recovered from it by making cultivation in CO_2?—Yes. (Witness afterwards submitted the following statement):—

Two series of experiments were done in this connection:—

A sample of ordinary garden earth was obtained, to this a considerable quantity of living plague germs was added. Some of the infected earth was emulsified in broth, and a portion of this emulsion was added to six broth tubes prepared for anærobic growths. The six tubes were divided into three series, two being treated to saturation with CO_2, two were treated to almost saturation, two were treated with just an excess of CO_2. They were incubated for three days. After this interval a control broth tube in which plague was growing in saturated CO_2 showed a distinct growth. Agar plates in three dilutions were then made and examined after two days, and again, after three days, but no bacillus conforming to all the tests for plague was found, although in two samples a bacillus, morphologically resembling plague, was found. The last-mentioned bacillus when grown on agar, in pure growth, grew more rapidly than plague. Further, when a portion of this growth was emulsified in broth and was inoculated in considerable dose into the peritoneal cavity of mice, the inoculated animals survived.

These anærobic tubes, when opened, had all a very strong smell, apparently of sulphuretted hydrogen.

The effect of H_2S gas by itself and the effect of mixture of H_2S and CO_2 on plague growth was there fore investigated. Another series of six tubes wa inoculated with freely infected garden earth.

In the present undiluted H_2S plague did not appea to grow, although a muddiness resulted in the brot from the deposition of sulphur from the H_2S.

In a mixture of CO_2 and H_2S there was slight growth H_2S was first passed in, then CO_2, so that while th atmosphere in the sealed tube contained little of H_2S some of this gas, probably, remained dissolved in th broth. The growth of plague occurred in chains, as i does in ordinary CO_2 broth cultures.

The six tubes which are in question were incubate for three days. They were then planted out on aga plates in three dilutions. These plates were examine daily for three days; I did not succeed in detectin bacilli that answered to all the tests of plague.

This is hardly to be wondered at, for agar plates o plague grow very slowly, whereas the bacteria foun in the earth grow very rapidly, by the end of thre days nearly all the plates were covered by othe growths than plague.

26,434C. Lastly, will you determine whether th virulence of the plague bacillus can be increased b making a series of passages through guinea-pig by the method which was successfully employed b Mr. Haffkine in exalting the virulence of the choler bacillus?—Yes. (Witness afterwards submitted th following statement):—

I have to report that I have performed five series o inoculations with a view to testing the possibility o increasing the virulence of the plague bacillus b making a series of intra-peritoneal passages throug guinea-pigs.

The method which was adopted was the following:—

A pure culture of plague was obtained and emulsifie in broth. A few minims of this broth emulsion wer inoculated with aseptic precautions into a guinea-pig peritoneum. The aseptic precautions referred to wer (*a*) the use of a sterile capillary pipette, (*b*) burning small area in the abdomen of the guinea-pig with re hot glass rod, and (*c*) the careful introduction withi that area of the filled capillary pipette. After death *post-mortem* was made with aseptic precautions. Th peritoneal exudation was removed by a capillary pipette It was then introduced into a test tube which was place in a slanting position in the incubator. It was allowe to remain there for 24 hours, when a few minims o the purulent exudation were inoculated into the secon guinea-pig. When this guinea-pig died the same pro cedure was adopted with a series of successive guinea pigs. The exudation was always examined microscopi cally before it was introduced into a healthy guinea pig. When the fluid was found to be contaminated i was rejected. The purity of the peritoneal fluid wa also controlled by cultivation.

Five series of guinea-pigs were inoculated in th manner which has just been described.

In each case the virulence was found to be increased

The following is the longest series of inoculation which was successfully carried out:—

Guinea-pig No. 1.—Inoculated intraperitoneally wit a 15 days old agar cultivation of plague (source fro which the culture was derived was not noted). *Died i 5 days.*

Peritoneal fluid removed and incubated for 24 hours.

Guinea-pig No. 2.—Inoculated with a few drops o above peritoneal fluid. *Died in 52 hours.*

Peritoneal fluid withdrawn after death was incubate for 24 hours.

Guinea-pig No. 3.—Inoculated intraperitoneally wit a few drops of above peritoneal fluid. *Died in 24 hours*

Peritoneal fluid withdrawn after death and incubate for 24 hours.

Guinea-pig No. 4.—Inoculated intraperitoneally wit a few drops of the above peritoneal fluid. *Died in 2 hours.*

Peritoneal fluid found to be contaminated by a thic long bacillus.

It will thus be seen that by the above method th virulence of the plague bacillus for guinea-pigs can b very rapidly increased.

In other series of experiments a degree of virulenc was obtained, such that when two or three drops of th exudation were introduced intraperitoneally the guinea pigs died some time during the night.

(Witness withdrew.)

(Adjourned till to-morrow.)

At The Secretariat, Bombay.

SEVENTIETH DAY.

Wednesday, 22nd March, 1899.

PRESENT:

PROF. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).

Mr. J. P. HEWETT.
Prof. A. E. WRIGHT, M.D.
Mr. A. CUMINE.
Dr. M. A. RUFFER.
Mr. C. J. HALLIFAX (*Secretary*).

Surgeon-General R. HARVEY, I.M.S., recalled and further examined.

Surg.-Gen. R. Harvey, I.M.S.

22 Mar. 1899.

26,435. (*The President.*) I understand that you have been making detailed inquiries with regard to inoculation in the Khoja community in Bombay; are you prepared to make a statement of the result of your inquiry to this Commission?—Yes, I am prepared to make a statement, but I am afraid that I cannot as yet give you any results. I find that the inquiry is a very much larger and longer one than I have had time to undertake. I have been hard at work ever since I got to Bombay and I have only touched the fringe of the subject. I have not been able to draw any inferences or conclusions or to get any definite information to enable me to draw such; for instance, we found that it is extremely difficult to ascertain the cause of death in the case of all the people who have been seen by medical men. We have taken the names and addresses of these medical men, and we intend to write to each individual so as to endeavour and get accurately the cause of death. We found the Jamaat books, the records of the Khoja community, are exceedingly accurate as regards the great majority of details, but they are extremely inaccurate with reference to the cause of death because a very large number of people are not seen by medical men and anything they are told is put down as the cause of death. Some of the entries are absolutely ridiculous. You find headache, you find asthma in a child of two years, and consumption in children of two years, and all sorts of impossible things of that kind. The inquiry, therefore, will take a very considerable time; but it is going to be continued, and the results will eventually be communicated. I estimate that it will take several weeks before they can get anything definite. I find that the original investigation of Professor Haffkine was one which involved an enormous amount of energy and thought. Although it is a very short report,* the amount of work involved in preparing it was enormous. I think that the records of the community are kept in a much more full and proper way than those of any average people; and therefore we ought to be able to get something definite out of them. At the same time you must remember that this is a community of from 10,000 to 13,000 persons spread about in the middle of a large city; so that it is not at all easy to follow the individuals; the results, therefore, will probably not be scientifically accurate. It will, however, enable us to form conclusions which are in the main correct; but they will not have the same value as those obtained under proper conditions from a smaller community. Several points have come out in addition to the fact that the records are correct. One is that the community as a whole have a most extraordinary belief in the efficacy of inoculation, though probably half of them do not accept it; there is a large number who have told me that the reason why they have not been inoculated was that they preferred to leave it to God,—that they were in God's hands, and that they thought it was not right to interfere with his decrees. So that a very large number of them, although they do not object to it and have nothing urge against it, do not actually accept it. I think it will probably be found that about half of the community are inoculated, and that half of them are not inoculated. We know, I should think, with practical accuracy from the Jamaat books those who have been inoculated and those who have not, so that we can get a very fair index as to the mortality among the two classes. Of course the difficulty is to get the actual cause of death. Another point is this. I have been asking them whether they know of any evil results arising from inoculation. Some of them have said that they heard it produced impotence and leprosy after variable times, but none of them have been able to tell me anything beyond hearsay evidence. None of them had had any experience of evil resulting from it. Most people think so little of it that a great many of them have been inoculated and re-inoculated three, four and five times. I was in hopes that one result of the investigation would be to give some indication as to the length of the protection afforded by the prophylactic. But in consequence of these constant re-inoculations, it will be extremely difficult and probably impossible to get any definite information with regard to it.

26,436. That was the main object of your inquiries?—Yes, and I am afraid they have been frustrated by the eagerness of the people to be inoculated over and over again.

26,437. Does any other point suggest itself to you which you wish to mention?—I do not think so.

26,438. Have you anything to say as to the selection of inoculated persons?—I think that in inoculations there is always a process of unconscious selection. Inoculations are performed mainly on those who come up for inoculation. People who are weak or who are sickly in any way do not come up. I have found repeated instances during the last few days of families in which the only person who has died (I have only been investigating the families in which death has occurred) has been the only uninoculated member of the family. On making inquiries as to why the individual had not been inoculated when all the other members of the family had been inoculated, I was told that the medical officers thought the individual was not fit for it or that he himself did not like to be inoculated because he was sick or old. The consequence of that has been that a considerable number of people, who ought by rights to be among the inoculated, because all the members of their families are inoculated, have died without being inoculated and have gone to swell the tale of the deaths among the uninoculated. I think that is the explanation. It brings the results of Prof. Haffkine's inquiries into the Khoja community out of the region of impossibility and makes his inferences much more likely to be true. The rates worked out in that inquiry seemed to me to be impossible. The deaths from all other causes than plague in the inoculated work out to only 3·33 per thousand per annum. That seemed to me to be an impossible death-rate in a community which included children and old people. I thought there must be some fallacy about it. I think that is the explanation with regard to it—that a considerable number of people who ought really to have been, and would have been inoculated if they had not been unwell, were included in the uninoculated, and went to swell the death-rate among them.

* *See* App. No. IV. in Vol. I. of these Proceedings.

Surg.-Gen. R. Harvey, I.M.S.
22 Mar. 1899.

26,439. Did you find any evidence of age selection?—In that report a considerable number of children and old people had been inoculated, but the number of inoculated was not nearly in proportion to the numbers in the population, and therefore Prof. Haffkine left out of calculation among the uninoculated children and old people.

26,440. (*Prof. Wright.*) Have you seen any facts which would lead you to suppose that the plague prophylactic confers protection against any other diseases?—At first I was very much staggered by that statement, because although one knows that the revulsive effect of one disease occasionally drives out another, it is not a common occurrence, and I certainly do not think it could account for the enormous difference in the death rate between the inoculated and uninoculated; but I find that Prof. Haffkine has been going (it is not a random assertion) on a large number of instances where people have believed—I do not say rightly or wrongly—that the effect of inoculation has been to stop other diseases from which they have been suffering for a long time. I think the effect can only be small, but it may possibly have occurred in a certain number of cases.

26,441. It is not forced upon you by statistical evidence which you have collected?—Not by statistical evidence.

26,442. When you compare the mortality among those inoculated Khojas, what will you take as your control? Will you take the mortality among the uninoculated members of the same family, or will you take the mortality among the other Khoja families who have not been inoculated at all, or will you take the total mortality of Bombay?—I think the fairest way would be take the mean mortality of the Khoja community.

(Witness withdrew.)

Mons. W. M. Haffkine, C.I.E., recalled and further examined.

Mons. W. M. Haffkine, C.I.E.

26,443. (*The President.*) Referring to the evidence you gave us when you appeared before the Commission on a previous occasion, I find that you undertook, if possible, to supplement the information you gave us with regard to one or two subjects. You told us that you had some exact data relative to the animals which had been treated with serum, which you thought you would be able to put in afterwards (*see* Question No. 133)?—The materials regarding the treatment of plague by serum of immunized animals could, unfortunately, not be analysed and put in order, owing to pressure of work.

26,444. (*Prof. Wright.*) I believe that before you proceeded to inoculate against plague you did a series of inoculations against cholera?—Yes.

26,445. Certain inoculations against cholera had been previously done by Dr. Ferran in Spain?—Yes.

26,446. In what respect is your method of cholera inoculation an improvement on that of Dr. Ferran?—I have little information as to how Dr. Ferran did his inoculations against cholera. A large part of the publications he made at the time were in Spanish and I am not acquainted with them. My information as to the manner in which he did his inoculations comes from the inquiry of the French Government Commission, deputed during the cholera epidemic in Spain to investigate Dr. Ferran's operations. Their report has been embodied in a paper by Prof. Brouardel, President of the Commission, and Dean of the Medical Faculty in Paris, but I am not aware whether Dr. Ferran put at the disposal of the Commission the details of the method he employed.

26,447. I was under the impression that the faults which you find in Ferran's system were that he used vaccine which was not sterile, that he used a culture which was of unknown virulence, and that he did not employ a standardised vaccine. Is that so?—The fixing of the strength of the vaccine is an extremely important point in all inoculations, though the urgency of that procedure differs with regard to different microbes and different vaccines, living and dead ones.

26,448. I am asking you with regard to cholera inoculation. I understand that your improvement on Ferran is that you used a perfectly sterile vaccine, and a vaccine the strength of which was actually known to you. Is that so?—Yes.

26,449. You think these two points—of employing a perfectly sterile vaccine and of employing a vaccine in definitely known doses—are the most important points in every vaccination. Is not that so?—Yes; they are exceedingly important.

26,450. How far have you been able to carry out, in the plague inoculations, these principles which you carried out so successfully in the cholera inoculation?—In the case of cholera, the method employed for having the vaccine of a fixed strength consists in keeping the pathogenic properties of the microbes at a given height by passages through animals. It is known that very great variation takes place in the power of the cholera microbes in causing the disease. When one compares cholera cultures of different origins, one finds a variation in the proportion of about 1 to 100; that is, the amount which is necessary for killing an animal by cholera may vary from 1 given quantity of virus to 100.

26,451. In the case of plague, have you taken any steps similar to those which you took in the case of cholera to ensure that your vaccines were made with a microbe of known virulence?—No, not systematically. The operations were conducted in a place where plague existed, and we were, in the majority of cases, getting for our cultures microbes from patients, thus obviating only the variations occurring in the laboratory. Apart from our knowing that it was a microbe which had produced a fatal effect upon men, we did not fix further its virulence.

26,452. Do you think you can assume that a microbe which is taken from a plague patient is always more virulent?—No; but we sterilized the vaccine, and measured the dose.

26,453. You say in your evidence that the virulence of the plague microbe can be easily kept up by passages through animals; have you made those passages through animals?—Yes; but we were unable to do so regularly. In the inoculation against cholera we pass the vaccine through guinea-pigs daily. So far as we can get guinea-pigs, the rule is that every day fresh specimens of microbes should be taken from a new animal. The work, however, always suffers from our not being able to do so regularly.

26,454. Would it be possible to do that in the case of plague?—I was not able to do so.

26,455. Would it be possible to do so if you had time at your disposal?—Yes; not only is it possible, but, as stated, in a large number of cases we do so. In the preparation of our vaccine we employed, whenever possible, microbes passed through rats and monkeys.

26,456. We may take it from you that it has not been possible to do it always, but that, theoretically, it would be possible if you had time enough at your disposal?—Yes, it is so.

26,457. You say that the virulence of the plague microbe is kept up by passages through animals; will you kindly specify the animals?—The microbes that we used were passed through rats and monkeys. At one time a number of experiments were done in the laboratory on monkeys, and the virus was transferred from monkey to monkey for other purposes, not specially for the inoculation against plague. Those microbes acquired a virulence higher than that which they had in the beginning.

26,458. Did you find the virulence to increase when you made passages through monkeys?—Yes.

26,459. Did you find the virulence increased when you made passages through rats?—Yes.

26,460. Did you find that to hold true invariably? We had it in evidence yesterday that, in the three series of experiments which were done in the Plague Commission laboratory here, the microbes died out instead of becoming more virulent?—In our case we employed only microbes that showed themselves virulent. In the experiments which were conducted in the laboratory we had specimens of microbes which, at the beginning, were less effective, and which, after they had been passed through five, six, or a dozen animals, acquired an increased virulence.

26,461. Do you think that it is feasible to obtain virulent cultures by this means?—Yes; not, however, by passing the microbe through monkeys.

26,462. Through what animals?—Most probably rats; it may require special precautions to maintain the power of the microbe if interruption of the series occurs.

26,463. Similar to those you took in the case of cholera?—Yes, precisely.

26,464. (*Dr. Ruffer.*) Have you been able to do that in rats yet?—Yes. As I stated, I did not do that continuously, but we had microbes passed through series of rats, and which maintained a high degree of virulence. But I never had sufficient leisure for that myself, and I never had an officer who could be put on that special task of daily passing microbes through animals so as to have the microbes always passed freshly through a rat or a monkey, or any other animal which we might select finally.

26,465. (*Prof. Wright.*) In addition to laying down that a microbe of a fixed and known virulence ought to be employed in making vaccines, you also lay down that a fixed quantity of microbes ought to be employed?—Yes.

26,466. How far have you been able to carry that out so as to estimate what quantity of microbes were contained in the doses which you prescribed?—In the inoculations against plague I never relied upon the measurement of the dose itself. At the time when I gave my previous evidence I said that we always relied upon the effect which the vaccine produced upon men. Our estimate as to the doses necessary for inoculation were always obtained from the reaction observed in inoculated people.

26,467. We have had it in the evidence of Dr. Milne that you hold up your bottles to the light so as to judge the opacity, and that in conformity with this you write the doses on your bottles?—That is so. The cultivation flasks do not grow uniformly. In a 100 flasks prepared from materials obtained on the same day, passed through the same processes, and inseminated with the same microbes, there will be a variation, and often a very considerable one, in the crops obtained. In this case there is an unequal degree of modification produced in the medium also. For determining the dose one has, therefore, to take into additional account the abundance of the growth also.

26,468. You do estimate the dose by holding up the bottle to the light and by judging of its opacity?—Yes.

26,469. Do you think that is a good method of judging the number of bacteria present?—It is possible that this is the most practical method.

26,470. Do you think it is a good method?—Yes.

26,471. Do you think it is a satisfactory method?—I have to estimate to what extent the method is satisfactory by the results produced.

26,472. We had it in evidence yesterday that a series of weighings of the sediment contained in individual doses brought out the fact that some of your doses contain between seven and eight times more sediment than others; in view of these weighings, do you think that your method is a satisfactory one?—Not in view of that, but in view of the results obtained from estimating the febrile reaction and comparing the richness of growth, it was satisfactory.

26,473. Is that a satisfactory method of standardizing?—I do not believe that the weighing of the sediment is a satisfactory method.

26,474. I asked you whether, in view of the results that were obtained by weighing, you think that one can arrive at a good estimate of the amount of sediment by holding the bottle up to the light?—I do not believe that, by weighing the growth, or otherwise estimating the sediment alone, you will obtain a satisfactory method of standardizing, and I never had recourse to that method. When I say I hold up the bottle to estimate the abundance of the growth I do not mean that that is the only circumstance which I take into account. I estimate the doses by inoculation in men and by observing the reaction produced.

26,475. I understand that method of standardization, but I do not understand whether you think it is a good method of standardizing, to judge the quantity of microbes by holding the bottle up to the light and noting the opacity?—I do not say that that is the only method I employ.

26,476. But you do consider that that method is satisfactory?—No.

26,477. We had it in evidence from Dr. Milne that the dose put on the bottle was judged by holding the bottle up to the light?—We shall not be able to analyse the matter satisfactorily unless what I say is taken into account fully. I stated that we estimated the required dose by the effect produced upon man. I must repeat that, when I have a batch of 500 flasks inoculated at one time on one day, or, say, in the course of three days, with the same cultivation of microbes, and I find that it produces the required amount of fever when injected in a dose of 2½ c.c., I still watch the abundance of the growth which takes place in the different flasks, and that abundance of growth is judged by inspecting the flasks and comparing the density of their growth. If, therefore, you wanted to standardize the vaccine simply by weighing the amount of sediment, it is most probable that you would never have any definite results.

26,478. That is not suggested to you. I asked you whether it is a good way of estimating the quantity of sediment to judge the opacity by holding the bottle up to the light?—It is a sufficient method of estimating when you compare additionally the result of inoculation in men.

26,479. Do you mean that your results on man are so constant that your method of standardizing must be perfect?—In all the inoculations which were done experimentally, under conditions deliberately chosen for testing the efficacy of inoculation, we obtained a fixity of results which probably is unequalled by any other series of experiments of the kind. In my evidence on the former occasion I enumerated the observations which we made in attacked communities. You noticed how little the protection afforded by inoculation varied. As long as it was so I consider the method selected as satisfactory, being at the same time adapted to the conditions of our practice.

26,480. (*The President.*) The question is not settled. We have not gone into the point as to whether the proofs you gave of the efficacy were, to our mind, satisfactory or not; you must not assume that?—In selecting my method I had, however, to judge by my results. In continuing to apply the method of estimating the doses which I followed, I had to watch the effect produced, and as long as the results answered my expectations I was justified in employing what I found to be practicable under the circumstances of our work.

26,481. (*Prof. Wright.*) I asked you if you were shaken in your impression that your method of standardization is a satisfactory method by the fact that sometimes the sediment is eight times larger than in other cases?—Not in the least; this most probably referred to microbes of different strength.

26,482. You said you have not tested the virulence of the microbes?—No; I tested the strength of the vaccine, not by the virulence of the microbes when injected alive into animals, but by the effect which the prophylactic produced on men, as is done by the vaccine lymph for small-pox.

26,483. We have been informed that, in a great number of cases, the vaccine was not tested on men in the laboratory before it was sent out; therefore, it was in those cases tested only by this opacity of the fluid, and if that is shown to be a defective method, I ask you whether it is not true that sometimes the standardization of the vaccine was insufficient?—The method was tested on men whenever it was possible. We made the best of the existing conditions.

26,484. I am speaking apart from the question of what was feasible. I ask you, as a mere scientific fact, whether the vaccine was always correctly standardized, and whether you would recommend this method of holding the bottle up to the light as an effectual method of standardization?—As long as we have no other practical method we have to follow this.

26,485. That means it is not a good method, because it follows that you must be looking for a better one; is that so?—I do not think that any attempts to find a better method will be successful as long as the inoculations themselves continue. (Note by witness on correcting proof of his evidence:—The answer in this form has no sense, and contains surely a mistake of the reporter. It should be as follows: "I do not think that our attempts to find better methods will ever cease as long as the inoculations themselves continue.") I never maintained that the methods we employed were all that I could desire.

26,486. (*Dr. Ruffer.*) What you mean is that you are satisfied there is no better method at present?—I, personally, had no better method applicable at the time.

26,487. (*Prof. Wright.*) A further question arises as to the sterility of the vaccine; have you anything to

Mons. W. M. Haffkine, C.I.E.

22 Mar. 1899.

say on this matter? We have had it in evidence that a good number of bottles were found to be contaminated. Do you think these contaminations are important, that is, did they affect the vaccine prejudicially?—These contaminations are a most undesirable factor, but I knew that the conditions of our work were not such as to permit of completely avoiding that factor. I was satisfied, however, that these contaminations, under the conditions under which they were likely to occur, were not a source of danger. They were mainly undesirable as endangering the efficacy of the prophylactic, and we took all possible precautions to avoid them. Our conditions of work, however, were not such as to secure this object fully. We continued to employ the means at our command because of the urgency of the time, and because I knew that the amount of risk which we ran was unimportant.

26,488. And you have come to the conclusion, with regard to the basis of your previous cholera inoculations, that it is not as necessary as you then thought it to be to employ a microbe of known virulence, and have absolutely aseptic vaccine? You think that certain divergencies from that rule may be permitted in the case of plague?—It is certain that even in plague, where we use dead vaccines, better results will be obtained if the above basis is strictly adhered to.

26,489. It has been suggested that an effect is produced upon gonorrhœa by injections of the prophylactic; do you know anything about that?—Not from personal observation. I had a verbal report from the medical officer, Captain Thomson, who made a series of observations to that effect, but have no personal knowledge on the subject.

26,490. Do you know what effect was produced by the injections?—No. I have no details. I understood that he was going to put this information before the Plague Commission.

26,491. (*Dr. Ruffer.*) I understood you to say that you had some experiments showing that there was some relation between the effect on man and the opacity in the bottle; can you put in those experiments?—Yes.

26,492. I suppose you have notes of those experiments, have you not?—We have notes in the shape of the reports of the inoculated people.

26,493. Can you add these notes to your evidence?—I would have to select them, but I will state at once what kind of information we have. The amount of growth which you obtain in a cultivation flask in one week is less than what you obtain in two, three, or four weeks. If you inoculate to-day a given number of flasks, and use some of them in a fortnight, while the others are permitted to stay on longer, there is a larger quantity of growth in the latter. The same dose inoculated from those different flasks gives a different reaction; the inoculation from the flasks which have been left to grow longer, and have a greater opacity, produces a higher reaction.

26,494. You are still of opinion that the fever is really the standard of the efficacy of the inoculation?—In the series of experimental inoculations, which was the basis of our work, we used that standard as an indication of the effectiveness of the material.

26,495. You stated, in the evidence which you gave before us three or four months ago, that you had a method by which a non-carbolized bottle could not possibly get into circulation. If you will remember, I asked you how you were sure that the bottle which had not been sterilized could not by mistake get into general circulation, and be used on patients, and you said that you had an elaborate method by which you could prevent that with certainty?—I did not mean a method, but we had arrangements made in the laboratory which would secure that.

26,496. Will you tell us these arrangements?—They have been enumerated in the rules for sterilization, which I have supplied to the Commission; since then we have introduced a controlling procedure which consists in the syphoning officers inoculating an agar tube with a sample from each flask.

26,497. To show the sterility?—Yes.

26,498. Have you any evidence to show that the prophylactic inoculation has any effect on leprosy?—No.

26,499. Or epilepsy?—No, I have no personal information on this point.

26,500. With regard to the statistical results of your inoculations, I have noticed in several places that the mortality from all causes, not from plague, among the inoculated is very much smaller than among the uninoculated; I think you found that out yourself, and put it in your* statistics of the Khoja community in Bombay. It was the same with the Khoja community in Karachi, and in the various communities which were inoculated in the State of Baroda. Have you any explanation of that fact?—In my Khoja* report I enumerated three or four circumstances which all probably took part in producing that result. One factor which influences the difference to a great extent has been mentioned by the Director-General of the Indian Medical Service in his evidence this morning. In a central station where people are inoculated as they come there is an unconscious selection, by weak individuals abstaining from inoculation. This tends to produce a difference in the general mortality, when one compares afterwards the inoculated and the uninoculated groups. This factor did not exist in the inoculations such as we have done in Undhera or in the Umdrkhadi Common Jail, where all the inmates agreed to be inoculated, but where the authorities only permitted a half of them to be done. In the instance of Umdrkhadi all the prisoners were paraded in 9 or 10 rows, and every second individual was inoculated. In the Undhera village we inoculated again a population agreeing to be inoculated in a body; the committee appointed to carry out the inoculations deliberately inoculated only half the members of each family, having their attention directed to making the groups of inoculated and uninoculated as comparable as possible. In these cases the unconscious selection is eliminated. Whereas at an inoculation station one will observe that a certain number of weaker individuals abstain from inoculation, mothers do not bring up very small babies, or old people do not come to be inoculated. This, however, is only one factor. Another is this. The mortality from general causes is generally low in the whole population during a period immediately following a severe outbreak, a large number of susceptible individuals having been killed off during the preceding period. It is certain that a number of deaths that are referred to general causes amongst the uninoculated are really deaths from plague, preventable by a specific treatment. This circumstance certainly renders the comparison comparison between the inoculated and uninoculated far less paradoxical than it looks at first. The last factor to be mentioned is the possibility of the inoculation against plague, or most probably inoculation of any pathogenic microbes, influencing also the course of diseases due to other infections.

26,501. I will put the question in another form. In Karachi there were 1,200 Khojas inoculated?—Yes, I believe, about that.

26,502. At Karachi we had the figures given to us of these 1,200 Khojas, and I find that not a single one had died from general causes in six months; do you think the explanation which you have given us just now is sufficient to account for that?—I am not able to estimate the extent to which it is applicable to that case.

26,503. You have no personal knowledge of the statistics of Karachi?—No. Moreover, in enumerating the three factors above mentioned, I am unable, and it is probably impossible, to estimate to what extent they are at work in each individual case. In the inoculations among the Khojas here in Bombay the observations referred to a period below four months, following a year when the mortality in that community han been just double the usual one, that is, it referred to a relatively short period following a severe epidemic. The mortality from general causes amongst the inoculated was exceedingly small, and I am able to take upon myself the responsibility of stating that no more deaths than those reported after my personal minute of inquiry occurred in that community. That is a circumstance which the Director-General, I believe, has now satisfied himself about completely in his present investigation. But even here I cannot distribute the result among the different factors that have effected it.

26,504. (*Prof. Wright.*) Do you think the presence of the supernatant fluid in the prophylactic is essential?—I have no information upon which to modify my views on the subject.

26,505. Upon what experimental evidence did you base the opinion that the supernatant fluid had an

* See App. No. IV., Vol. I. of these Proceedings.

important influence in conferring protection?—That was a circumstance which, in my first evidence, I asked permission not to discuss. I should like to avoid the consideration of my plan of work from a general or theoretical point of view.

26,506. I am not asking you from a theoretical point of view; I am asking if you have made any experiments which support that opinion?—I cannot support it except by the consideration of the results actually obtained.

26,507. (*The President.*) Have you any experimental data?—The results as observed on men are the only ones. I introduced the supernatant fluid in the hope of reducing the fatality of attacks in inoculated.

26,508. (*Prof. Wright.*) But you have never tried to inoculate some men with the sediment alone and others with the liquid alone?—No, not yet. In a letter, No. 260*a*,* which I addressed to the Government nine months ago, I sketched out a plan by which this could be ascertained, but I was unable to carry it out yet

26,509. When you judge by the intensity of the fever produced by the inoculation in cases where you inoculated as large a quantity as 15 c.c., do you not think the peptone contained in the prophylactic itself might account for some of the fever?—The experiments were not made in these conditions. We have the best febrile reaction with small doses of prophylactic.

26,510. In the particular case where you inject a large quantity, do you think there is that possibility?—Yes, but when we inject large doses it is because we observe little fever.

26,511. Have you made any experiments upon men with peptone?—No. One of the officers in my laboratory, Dr. Mayr, is to make those experiments, but they have not been made yet.

26,512. As far as your present information goes, you would object to eliminate the supernatant fluid?—I would decidedly.

26,513. On *à priori* grounds?—Yes.

26,514. But for no other reasons?—As long as no other treatment has been shown to be as effective as the one employed, it is inadmissible to modify it. All alterations must be justified by results actually obtained.

26,515. If experiments were brought before you showing that no protection was afforded to animals by the supernatant fluid in your prophylactic, if, for instance, the filtrate from your prophylactic proved to be no more toxic to animals than the original nutrient medium which is employed as a culture medium for those plague bacilli, would you then think there was a reason for eliminating the supernatant fluid from your injections?—I would not dare to eliminate it in the treatment of human communities until restricted observations, as mentioned in my letter to Government, would show that admissible.

26,516. But you have no experimental evidence to show that it is useful. If you had experimental evidence of animals to show that it was useless, would you still persist in using it on men?—I would not adopt a modification in the general practice until exact observations on men showed such a modification to be admissible.

26,517. Pending observations on men, if the experimental evidence of animals seemed to show that the supernatant fluid conferred no benefits on animals, would you still approve of employing the filtrate on men?—Yes.

26,518. Why?—When you try the effect of the treatment on animals under special conditions you may fail to detect in the whole of the prophylactic fluid any elements justifying its application to men. Such was the case with the experiments carried out in London, in St. Bartholomew's Hospital, in an attempt to immunize guinea pigs against the plague. *A fortiori*, when you examine the material, not as a whole, but from one particular standpoint, and fail to detect reasons for a particular component of the prophylactic, that would not make me less diffident to adopt the conclusion based on your experiment. In the inoculation against cholera, many experienced investigators, after prolonged and careful experiments on animals, came to an absolutely negative result as to the efficacy of the method, whereas the inoculation in men proved to themselves and to others the striking efficacy of the method.

26,519. In your experiments with regard to cholera inoculations you were instigated to do your experiments on men because the experiments on animals had proved successful?—Yes, and with regard to the inoculations against the plague that was the case also.

26,520. If experiments, often repeated on different animals, showed that the supernatant fluid conferred no protection, and was not more toxic than the original nutrient fluid, would you then abandon it?—No. At the present stage of our work I would admit only a guarded attempt on an isolated group of men, and restricted experiments made and repeated with regard to that particular point.

26,521. Do you prefer to do your experiments on men to doing them on animals?—For establishing final results, for proving a method completely, it is impossible to rely upon any other experiments than experiments made directly on the species of animals which is expected to benefit by them.

26,522. But if all experiments on animals showed that the thing was noxious, or no use, would you still recommend it for men?—I would first distinguish between useless and noxious. It is, however, evident that if I myself had made a series of experiments on animals and found a method useless, I would have no inducement to try it upon men.

26,523. Pending the information, obtained from results of animals, that the supernatant fluid is of benefit, why do you still say it should be used on men?—That brought us unfortunately to a kind of discussion which I was trying so much to avoid, viz., as to what extent my considerations were sufficiently sound to induce me to apply the method I devised. I stated in my first evidence, that in acting as I did I made use of all my previous experience and knowledge, and might have been as easily mistaken as be in the right. It so happened that the method I employed answered entirely, in all particulars, to my expectations. I had, therefore, up to now, no reason to be shaken in my reasoning, but should like to avoid discussions on this point.

26,524. You think that your own opinion, independently of any backing up by experiments on animals, is sufficient for you to use the supernatant fluid?—I have backed up my opinion by the results on men.

26,525. Are the grounds you refer to, to be found in your experiments, or are they to be found in your imagination?—Mr. President, I beg your kind permission to withdraw now from this discussion.

26,526. (*Dr. Ruffer.*) Have you any facts, from experiments made on animals, in connection with plague, to show that the supernatant fluid is of use in producing immunity?—No, not on animals, and I should add, such experiments are impossible.

26,527. (*The President.*) I think you said you still believe that the pyrexia was a good gauge of the preventing influence of a preventive such as the fluid you have been using?—Yes.

26,528. You think that the pyrexia as distinguished from the quantity of the preventive substance which you have introduced is really a true indication, or a true reason, of the protection?—It seems to be a satisfactory practical guide in using the plague prophylactic.

26,529. Is it a question of fever or a question of the introduction of a certain quantity of antidote, or is the fever a mere unavoidable accident because it is an effect which that thing will always produce?—I have no grounds for believing that the immunity is produced by that rise of temperature, I mean I have no grounds for determining the actual part which the rise of temperature plays in producing the final resistance. But I have adopted the rise of temperature as an indication of the activity of the vaccine; and this indication guided us satisfactorily in our operations. In the inoculations where we observed that the prophylactic failed to produce a sufficient febrile reaction the results were lower. On the other hand, whenever we had a prophylactic which, when injected in moderate quantities, produced a high degree of fever, the results were more satisfactory. It is on that account that we accepted and followed the above indication. In the first experiments in the Mufassil, in Lanauli, and in Kirki, I had a material which I had to inject in increased doses in order to obtain any marked degree of fever. I had finally to content myself with a lower temperature, and the results were less satisfactory. In Kirki for instance, where the difference in the mortality between the inoculated and the uninoculated was only 77·9 per cent., I had a material which failed to produce a sufficient febrile reaction when injected even at a dose of 10 c.c.

26,530. You have no idea of how much of any special chemical substance was present in the fluid?—No.

26,531. (*Prof. Wright.*) Have you any special knowledge of the results in Kirki? We were told in

* *See* App. No. LXXXII. in this Volume.

Mons. W. M. Haffkine, C.I.E.

22 Mar. 1899.

Poona that the records in Kirki were kept so badly that nothing could be made out of them. Did you have a special report?—I have not embodied my observations in a special report, but I have all the information and documents to show that the statement which has been made to you in Poona is incorrect. I have in my laboratory all the papers referring to the composition of the families and all particulars as to the occurrences of plague in the inoculated and the uninoculated.

26,532. There must then be two reports, one inaccurate, which was the one which Col. Fawcett was speaking about, and another, an accurate one, which you have. Has your report been communicated to the Commission?—The results have.*

26,533. I understand there was a report kept of results in Kirki locally, and that that report on examination was found to be absolutely unreliable. In addition to that it was suggested that you must have had a special report made to you by a special reporting officer?—I was myself on the spot and collected the information personally with two assistants.

26,534. Have you communicated that information to us?—I have communicated the final results, the number of the inoculated and uninoculated, and the occurrences of plague among them. But the documents which I have in my laboratory have not yet been embodied in a report like that made out with regard to the Daman or Undhera outbreaks.

26,535. Your figures were based on personal inquiries?—I was in Kirki during nearly the whole of the epidemic, and was visiting the infected barracks and the Plague Hospital twice a day; and all the information I have is in my own handwriting, or in that of the assistants who were with me.

(Witness subsequently put in certain statements A., B., and C., regarding Lanauli, Kirki, and Undhera, which are published below; and he also put in a statement which, at his desire, is published as Appendix No. LXXXIII. in this Volume).

Mons. W. M. Haffkine, C.I.E.

22 Mar. 1899.

(Witness withdrew.)

The Hon. Sir ANDREW WINGATE, I.C.S., K.C.I.E., recalled and further examined.

Hon. Sir A. Wingate, I.C.S., K.C.I.E.

26,536. (*The President.*) I understand that you are prepared to continue some statements with regard to plague which you favoured us with up to a certain date when we last had the pleasure of seeing you. Will you kindly continue those statements?—When last I had the honour of appearing before the Commission, I was asked if I would prepare some maps showing the results of plague infection. The points in these district maps I now put in,* to which I would invite attention, are as follows:—The date of the first case in each of the three epidemics is given under each village. The three epidemics are distinguished by colours; the first is shown in red, the second in blue, and the third in green. This map (*pointing on map*) being of the Dharwar district, the infected villages are all in green. If you take the total plague recorded deaths up to the week ending the 3rd of March 1899, you will see that they are 94,000 approximately.

26,537. Is that in the Bombay Presidency?—Yes, in the Bombay Presidency. Those are the figures from the published weekly list. During the current year in the Belgaum and Dharwar districts, there have been 17,000 and 30,000 plague deaths respectively up to the end of the same week, the 3rd of March; that is 47,000 deaths in those two districts, which is half of 94,000, the total plague mortality of the Presidency, including Bombay City. One-half of the mortality up to date in the current year has thus occurred in these two practically newly infected districts. That seems to indicate, as compared with the 61,000 recorded plague deaths of the previous year ending May 1898, that, over the very large area of the Presidency generally, the present epidemic has been of a more restricted character—I cannot use the term milder where the percentage of deaths to cases continues so high. I should like to invite the attention of the Commission to a fact that they will see in nearly all the maps, that although, for example, there have been 30,000 deaths in the Dharwar district, these deaths are nearly all confined to this part of the district (*indicating on the map*). This localization is well emphasised in Hubli taluka. Hubli town is *here*. These green marks, as you will see, cluster round first, the town, and then the taluka, though, as you will see, a more distant village is here and there infected. The point is that the spread of infection appears to me to be the same in the country as you find it to be in a town, that is very localised at first, and spreading from a given centre. It is precisely the same if you extend your glance over the whole of India. The Bombay Presidency is the infected area, while the rest of India remains practically free. It is very striking. In every map you will see huge areas—highly populated areas—without a single case, or perhaps one or two only over a whole district. That seems to me to indicate that the outflow from an infected area is probably more dangerous close to the centre of infection than at any distance from it, that as the outflow gets further away from the centre, so the danger seems to lessen. Take the case of a man, starting from an infected house: if he goes 10 miles in two hours, he appears to be more dangerous than if he has gone 20 miles in four hours. Or it may be that the local spread of infection is due to entry into an infected area. It may be a market town which is infected, and where you have a market town the people from all the villages round go into the infected area: and, therefore, you get this localised infection. Into Ahmedabad or Broach the exodus from Bombay I presume has been as constant and as great in the past three successive years, but it is only this year that North Gujarat has been attacked. Take the town of Broach. You will find that it was not until Ankleshwar village, within 10 or 12 miles of Broach was attacked, that Broach was infected. That seems to me to point to the fact that the danger to Broach was not the incoming of people from infected areas at a distance, but either the outgoing of the people from Broach to an infected place within their easy reach, or the entry of people from a neighbouring infected village into Broach. You may say that the people of Broach went and came also to and from Bombay. That is so, but there you introduce two fresh elements—the one of distance and exposure to sun and air when going back to Broach, and the other of the medical inspection and the disinfecting arrangements, whether they involve detention or merely inspection. The people who go from Broach to Bombay by rail, and go back, come under those restrictions; and, therefore, are to a certain extent not so liable to introduce infection, as when the infected area approaches close to a town. And there is the further danger that it is by the people of the town visiting that infected area that plague is also carried. All I wish to point out is, that as the Commission will examine our maps they will almost invariably find that the infected places are grouped; that when they hear of a district with 30,000 deaths in it, and expect to find the

Hon. Sir A. Wingate, I.C.S., K.C.I.E.

22 Mar. 1899.

whole district a mass of plague, it is nothing of the sort. The plague is absolutely localised in certain parts of the district. It is just the same when going into a plague infected town; you will be taken to one or two infected streets, and it is there where you have the chief mortality.

Turning now to the point that was aimed at last year, trying to detain the outgoing population of an infected place, I have a few figures which I brought with me which I should like to show you of the needlessness, after experience, of putting the people to a vast amount of inconvenience. Last year at 12 stations during a period of 5·14 months, 131,074 people were detained for periods varying from 5 to 10 days. Out of those 131,000 people, 201 cases of plague were detected, and nearly 131,000 people were disinfected. At 14 stations this year, during a period of 3·8 months—a shorter period—116,000 people have been disinfected, against 131,000 in the previous year; and 160,000 people haven been subjected to the clinical thermometer test. Out of these nearly 12,000 people have been detained on account of a rise of temperature, and 266 cases of plague have been detected. It is too soon to say what the results in the districts may be of the re-infection from Bombay. You cannot tell that until the next two months have expired. Up to date, at all events, the proportion of the exodus of the two years is not very dissimilar, and 266 cases of plague have been caught, against 201 in the previous year; and only some 12,000 people have been detained instead of 131,000. From what I know, I think that the medical examination has been still more thorough than the detention, and has probably led to fewer cases; I say fewer cases, because if you get a case into a camp, there have been a good many instances of cases after 9 days, 11 days, and 12 days, which seems to me to point to infection within the camp from one to another. On the other hand, by the use of the clinical thermometer, and the detention of all people who show the least temperature, 266 cases of plague have been detected, and apparently now the cases all develop in the first few days. These statistics seem to me to indicate that there is a very small amount of risk from the exodus of the population of an infected town under precautions for carefully medically examining the people. The major part of the exodus from Bombay has gone by sea. Our infected ports up to date this year have been two small places in the Kolaba district, and one, or perhaps now two, in the Ratnagiri district, comprising a very small number of cases of plague. These are considerations which seem to me to indicate that under proper precautions, plague is not a thing to terrify people who are at a safe distance, and who are not likely to go into the infected place itself.

26,538. Do I understand that you are of opinion that this railway examination is valuable?—Most valuable. It is not only valuable because of the cases which it detects, but it is probably still more valuable in preventing sick people from leaving the infected areas. If you look at the weekly list for the Thana district, where the restrictions this year were specially relaxed compared with the year before, you will see that there were 756 imported cases in the first year, and 163 imported cases last year, when there were detention camps; whereas this year the number has increased to 212 up to date. These figures are not confined to cases imported from Bombay, but indicate generally the variations in the number of cases imported from Bombay. In the Thana district, last year, there were less than 1,200 deaths, whereas this year there have already been over 3,000. The medical examination was purposely taken off between Bombay and one part of the Thana district, in order to give a certain amount of play to the Bombay population, and not to tie them up too tight. The medical examination acts in those two ways—that you catch the case that does go out, and you prevent from going out a great number of cases which would otherwise go out.

26,539. Do you think the great trouble involved is quite justified even by stopping 266 infected persons?—Do you mean trouble to the people?

26,540. Everyone; to the officers employed, and the people subjected to examination?—I do not think that there is much annoyance from a simple medical examination.

26,541. I do not mean annoyance—trouble or expense?—There is a certain amount of trouble, and there is a certain amount of expense; but if the examination were taken off, I think that the country would be flooded with plague cases immediately.

26,542. I quite expected you to say that, it is obvious?—I will prove it. Take the town of Hubli. How were all these places round the town infected? Had it been possible to have a medical examination, by the thermometer, of everyone going out of the town, and to detain everyone showing any excess temperature, the chances are that spread of plague would have been less in that part. The other danger, which I indicated to you, of people going into Hubli, would, perhaps, have remained. Persons who go into the infected house, or into the infected area, are susceptible, and may come out infected.

26,543. Have you anything to tell us about evacuation?—This map of the Dharwar district probably represents the state of things as they existed at the end of the rains. Perhaps another 50 or 60 infected villages have been added since; but had you seen the map at the end of the rains, it would practically have been something like it is now. The extent of infection represented makes it look like a hopeless task to anybody, unless you put in an army of people to deal with it. By simply putting in a few English officers—about 10 or 12—and working with the people, not doing anything by force, but working with the people on our side, the results I venture to think have been very remarkable. There was a percentage of deaths on the total infected population of 6·8 before evacuation, and after evacuation the percentage fell to 3·2. There were 17,000 odd deaths before evacuation, and there were a little over 7,000 after evacuation. If I had been able—but I regret to say I have not been able yet—to find out how many of the 7,000 deaths occurred in the first ten days after evacuation of each particular village, I have no doubt we could show our results in a far more striking light. Still, taking it broadly, there were 114 infected villages, with 17,467 deaths, up to the 11th of November 1898. I should like to show you this statement, showing the total plague mortality of the Dharwar district at the same time, as follows:—

DHARWAR DISTRICT.

* The figures are taken from the daily reports.
† Hubli and Dhárwár.
‡ Dhárwár.
§ Hubli has been added to complete the total.

Note.—Villages in which the figures and facts are not reliable and those which had imported cases only are omitted.

You will see that from the middle of November, when evacuation began to take effect, the death rate immediately began to decline. After evacuation, there were 143 freshly infected villages (excluding the 114 I mentioned before), and there were 7,185 deaths after evacuation. That gives, previous to evacuation, an average of 151 plague deaths per village, and after evacuation, of 50 deaths per village. From the figures, you will see that the Dharwar district has declined from a weekly mortality of over 2,000 to a weekly mortality of about 74. This improvement has been gained, I think, almost without a single prosecution, without almost a complaint, and practically by the people themselves, under the guidance of a few

Hon. Sir A. Wingate, I.C.S., K.C.I.E.

22 Mar. 1899.

officers. The evacuation of villages is now so well understood, that we are continually hearing of villages where a few dead rats have been discovered, and the villagers have, of their own accord, immediately vacated their village. They are continually vacating villages now, of their own free will. Therefore, I think, that in future the expenditure is capable of great reduction, because we shall be able to rely more and more upon the voluntary intelligent action of the people. The people are coming forward in a most splendid way, not only to bear the great death rate when it attacks a particular village, but in the way of self-help. I think, considering how very exposed they are to infection, and how very liable they are to take it, that the way the people are coming forward to carry out the measures which they are convinced are necessary is most creditable to them. Up country, I think I am right in saying that, in small towns and villages, particularly during the fair season, there need be very little difficulty in checking an epidemic. Infection was very quick here (*indicating on the plan*). It has thrown out a great deal of plague in various directions, but from the moment evacuation came in the spread of the disease has been checked. Evacuation acts in this way. First it checks the epidemic. If it is done early in the epidemic, it will check the epidemic absolutely; if it is done after an epidemic has become pretty severe, it will bring down the mortality very rapidly. Evacuation will therefore lessen mortality; and it will decrease the duration of the period. If information is got early, and evacuation is prompt, your epidemic may only last a few days, or a few weeks, and thus curtailed, the spread to new villages is arrested. The longer an epidemic lasts in any particular town, the greater the danger of the infection spreading. On the other hand, if you have turned out the population of the infected village to live in their fields, the villagers from villages all round do not visit the infected area, and there is no danger from visits to the evacuated population.

26,544. In the favourable figures which you give us, I suppose you include cases in which evacuation was carried out in circumstances which were not the best for the evacuation—where it was done late in the epidemic, and so on?—Yes. All villages are included. Evacuation was begun late because of the rains. It might very reasonably be said: "The epidemic has "stopped of itself; it is an accident that your evacua- "tion measures began in November, when the thing "was going out of itself; it is a declining epidemic." To that I would invite your attention to the figures in the Bijapur district, which is in all soil and climatic conditions very akin to parts of the Dharwar district which were infected, and where evacuation was able to begin immediately. If you compare the villages, they are few in the Bijapur district, though a certain number of new villages are always being attacked. If the mortality be compared, in the Bijapur district there are seldom more than 25 to 50 cases per village, frequently much less; whereas in the Dharwar district, during the rains, there are few villages which did not suffer severely. I will take one village of 1,280 people. There were 424 deaths—that is 33 per cent. of the population—was carried off. In another village of 4,222 souls, 922 persons died, or nearly 22 per cent. That just shows what plague can do if circumstances are such that the people cannot help themselves, nor can the Government help them. The problem now before us, I think, is solved, with regard to the method of dealing with plague up-country during the cold season—which is the dry season for up-country. I think plague is always capable of being controlled under these circumstances inexpensively and comparatively without compulsion or coercive methods which are very unadvisable to resort to. The problem still unsolved is: What are we to do in the next rains, when a town or village has been infected? Our experience up-country has been that the villages which have been attacked during the rains have mostly occasioned a great spread of infection. Take Igatpuri, Sirur, Belgaum, and Hubli; in every case the attack has been during the rains, and in every case the spread has been very serious. There is another point, perhaps, to consider, upon which I can offer no explanation, although it seems to me to be somewhat borne out by the maps, namely, the fact that in the Deccan the spread does not seem to be so rapid or violent as in the black soil districts of Satara, Kolhapur, Belgaum, and Dharwar. The seizures appear to be very rapid in those districts. There is no apparent reason why a town like Poona, or say Sirur, when attacked, should not have produced the same tremendous spread as has been the case further south. There seems to be something which I cannot venture to explain. I only offer it as a fact which I have observed.

26,545. With regard to the black soil districts in the rainy weather, how do you propose to deal with an epidemic?—If evacuation is considered to be impracticable, the only thing that I think is feasible in the rains would be to prevent the population from leaving save under restriction. To confine a population has always appeared impossible, as being inhuman. But given inoculation, I think it would be quite feasible to say to the population—"You can be inoculated or you "can leave the town after temporary residence in a "camp or you may stay in the town." We might offer a protective prophylactic, but leave an open door under certain precautions. Probably medical examination by the clinical thermometer and disinfection of all articles of clothing and bedding would prove sufficient without temporary residence in a camp, and in any case the inoculated must be subjected to these precautions. Then it might be necessary to control the entry into the town, because although the residents may be all inoculated, it seems to me that the town itself may be infected. This surmise is due to what appears to be the difference between plague and every other disease, namely, that plague attacks animals, particularly the domestic creature, the rat. The rat in India runs at night about everybody's house and over and about the sleepers on the ground, and therefore although you may have an absolutely protected because inoculated population, yet if plague were imported into the town, and the rats caught the infection, it is quite possible that there might be a certain amount of local infection independent of people. To what extent that may be the case I am not prepared to say, but there is this fact which is very difficult to get over, and which all our officers have had experience of over and over again,—that when an evacuated population re-occupies the village site and the villagers open up and clean the houses (the rats naturally go into the roofs and other places), a certain number of plague cases sometimes result—perhaps very few—even after the population has been free from plague for weeks before they go back to their houses. That seems to be explainable, not by the fact that the whole place has remained infected—for if it had been, everyone would have got plague when they came back—but by the probability that, a day or two before, some diseased rat had infected the particular house in which the fresh plague case suddenly occurs. I do not think the infection lasts long. Localization of the disease appears to imply that the infection cannot be a permanent one, since it is rarely carried to a distance. I hope in the next two months the Dharwar district will be absolutely clear, because there are no big towns now infected. Therefore the situation there, I think, is a very hopeful one.

26,546. Have you arrived at any conclusion as to the maximum population of a town that might be evacuated under ordinary favourable average conditions?—I would not resort to total evacuation in any town—in which the people did not themselves desire it—in which the population was over, say, 50,000 or 60,000. I daresay evacuation could be done quite easily up to 100,000. Even in the case of a town of 50,000 or 60,000, I would hesitate if the people objected. Take an example of Broach, which has just been infected. The Collector there, with only partial evacuation, seems to be carrying the town through what would be a very severe epidemic, with a comparatively small mortality. I do not think there are more than 5 or 6 cases a day, whereas there ought to be 20 or 30 according to previous experience, and the time the epidemic has lasted. The mills are all working, and the trade but little interrupted, and everything is done with the goodwill of the people. There is no great spread of infection to the surrounding villages. I do not attach very great importance to a certain spread from the town, because from experience in Sholapur, or Admednagar or Malegaon or Jalgaon, all places which have been completely evacuated, the infection has been checked directly the townsfolk have gone out, and the surrounding country has been cleared very rapidly of any infection which has followed the evacuation. I do not think that the villages are of much importance, except near towns; but when a village gets infected near a town, it ought to be absolutely evacuated at once, under precautions that the villagers cannot enter the town.

26,547. You do not, therefore, think that the mere ocess of evacuation is likely to extend the plague to e surrounding country especially?—No; I think that evacuation is done in the early stages it certainly will ot. The only time it does extend the plague is when ou get a very badly infected place, and turn all the eople out. The result is that you stop a dangerous idemic, and immediately infect 10 or 20 villages; but ou turn these villages out at once. It takes a few weeks get the place clear, but it is done, and the epidemic over. I mean there is much less danger, as it seems me, in evacuating a town like Sholapur, at the risk f 10 or 20 villages being infected, and having two or ree cases in each village, than in keeping a central lace like Sholapur infected for, perhaps, eight or ten onths, during which time the infection may be going ll over the country.

26,548. In either case there is a necessary risk of xtension from the infected area, but on the whole you hink that that the risk is almost smaller, where perfect vacuation has been adopted, than where the disease is llowed to run its own course?—Quite so, and the uicker the evacuation the less the risk.

26,549. Is there any other point you would like o bring before us?—I present this chart,* exhibiting he weekly total mortality of Bombay City to the Commission made up to date. I think it is a very emarkable chart. It is what we have had to guide us n Bombay City; it is the expectation we have followed oth before and since the present epidemic re-appeared. It seems to me to point to certain conditions of the epidemic which are, perhaps, controllable—I will not ay they are controllable, because I cannot say how far what we do may influence or not influence an epidemic. I hear statements that the epidemic is infinitely worse this year, and that we are going from bad to worse, but I do not think so at all. The total mortality last year in Bombay was over 55,000; we are now up to 40,000 deaths from all causes, and we have only two more months to run. I do not think we shall reach the 55,000 of the previous year in this present epidemic. Of course, I cannot tell what is in the future, but if the epidemic goes on as it has done, we ought to have only another week or two before it falls. We do not know how long the high mortality may continue up and down, forming what I may term a truncated cone on this chart, but the turn appears to have come just as it did last year.

26,550. Could you very briefly tell us what are the measures which are being adopted at the present moment in Bombay?—The two principal measures which are being adopted at the present moment are those which have been in force all along. Where a house is unsuitable for the patient to be treated at home, he is taken to hospital, and I am glad to say that I think in almost every instance the patient goes perfectly willingly, and with the concurrence also of his friends, some or all of whom accompany the patient, the reason being that the hospitals now are as attractive and comfortable as probably it is possible to make them. The only difficulty that I can see in the way of hospitals being thoroughly popular in this particular epidemic is the terrible death rate. As an exception, I may mention, the Plague Hospitals in Dharwar and Gadag, where I think there was a very considerable number of inoculated patients. The returns from these two hospitals are certainly remarkable. There are no two hospitals in the whole of the Presidency, so far as I am aware, which can show the same results in cures, and I take it that that is due to the proportion of inoculated patients who passed through the hospitals. I do not see any other reasons, because the death rate outside the hospitals was pretty stiff in the Dharwar district. There was no less virulent type of disease there.

26,551. From the evidence we have, we understand that very few inoculated persons have had plague at all in Dharwar?—In the hospital statistics of Dharwar and Gadag, you will see that there is a certain number of inoculated people who were admitted into the hospitals, of whom comparatively few died, and that, I think, must tell on the general percentages of recovery.

26,552. What further measures are being adopted now in Bombay?—There is evacuation of the infected house, if the house is not of a nature to be disinfected immediately, and the people allowed to go back immediately. If, for instance, it is a crowded and extremely badly constructed house, then there is evacuation, but it is a short evacuation. That, again, is a difficulty in Bombay. The people would go out a great deal more readily if they had not to go back again, but they do not like going back to the houses again—they would prefer to remain in the camp.

26,553. Because they are frightened of plague?—No.

26,554. Because they like the camp?—Yes. Directly they are out they infinitely prefer the camp. The great trouble is to get the people out. That, I have found, was the same in England. When I went to see a segregation building in London, I asked the Health Officer if he had much trouble in getting the people there. He said that there was a great deal of trouble in getting them there, but that they had sometimes to smoke them out. It is the same here. You give them a very comfortable, light, airy place, compared with the den from which they came. It is, of course, only the very poorest who go to these camps.

26,555. They appear to appreciate the surroundings?—Yes, and the absolute safety from the plague.

26,556. Are these the two great measures which are now being followed?—Yes.

26,557. Putting it generally, they are not quite so stringent as they formerly were in other epidemics in Bombay, are they?—The difference now is that perhaps there is not the house searching, but I do not know that that led to any more cases being discovered than now. Some people think that there were more cases found last year, and others think that there were less, but in all statistics you require to look very carefully to see how the figures are compiled before you accept comparisons.

26,558. House searching was not favourably regarded by the people, I think?—I think if measures have any effect at all upon the progress of the epidemic—if we assume that the present epidemic will begin to fall in the course of a short time, a few days or a week—if, that is to say, the present epidemic is going to draw the same pattern upon that chart which it has drawn in the two previous years, and if the measures have any effect at all upon the drawing of that line,—it stands to reason that the measures in the three epidemics have been very nearly equal in their effects on the mortality in proportion to the population. The measures may have some cumulative influence, or the epidemic may be waning, because the death-rate, in proportion to the population, seems to become rather less each year. The death-rate was highest in the first year, rather lower in the second, and I think will be lowest in the third; therefore showing that stringency does not lead to any better results than relying on the co-operation of the people, and not advancing in front of their intelligence, or rather driving them against their intelligence, but waiting until you can take their intelligence along with you, in which latter case you get far better results every year. I look forward to the intelligent co-operation of the people in Bombay with great hopefulness. I think, if the epidemic is to be conquered, it will be conquered through and by the people, as every other great reform in India always has been.

26,559. I understand there is a considerable exodus from Bombay at the present time?—There is some exodus, and perhaps you are right at the moment in calling it considerable, but that is only true of the exodus during the last week or two. During December of 1897, and January and February of 1898, 94,893 people left Bombay in excess of arrivals. In the same three months of 1898–9 the excess was 115, 863, a difference of some 2,000. Considering that this year the population has been very much larger than it was in the previous year, and that trade and the going backwards and forwards have been much brisker, the difference of 21,000 in the two years is a mere bagatelle—it is not worth talking about in a great population of 900,000. No doubt, if we had the figures before us of 10 years back, we should find that in one year there were 20,000 who left the town; in another year 30,000, in another year 5,000, and so on. But undoubtedly there is a difference this year. If you take the individual months, you will find that in January 1898, 52,430 people left Bombay, and in January 1899, 40,444. Up to that date there is no difference. This year, in fact, fewer left in January in proportion to the population than in the previous year. This deficit is made up by only 38,489 going out in February 1898, against

* *See* App. No. LXXXV. in this Volume. The chart was later completed up to May, 1899.

Hon. Sir A. Wingate, I.C.S., K.C.I.E.

22 Mar. 1899.

79,481 going out in 1899. You may say this exodus in February is due to the increase of plague, or you may say it is due to very much fewer people having gone out in the month of January, compared to the month of January in the previous year, but taking the whole three months together there has not been anything unusual. Then at this time of the year the harvest is going on up-country, and there are perhaps two or three hundred thousand people who have come temporarily into Bombay, many of whom, after earning their bread here for two or three months, go back to their harvesting, and therefore, if there is an exodus now, I do not think it is very much in excess of the exodus which would take place in an ordinary year. The difference this year is, perhaps, that people are not coming in so freely to replace those who are going out, which very often happens. In the first 17 days of March last year, 18,234 people left, and this year, in 17 days, 53,980 have left. Last year the epidemic was going down during that period, or at all events was not very bad. There is the difference between 18,000 and 53,000.

26,560. Assuming there is no important difference in these two years, there is at the same time some slight difference at any rate?—There is some slight difference, but I should like to say that it is very much less than than we expected. Last year we tied up the town, we had the gates locked, so to speak. This year they have been opened absolutely, and we expected an enormous exodus, which, however, has not taken place. The reason we expected it was that last year the natives all said we would not let them go out, and that they were dying here.

26,561. Assuming there is no important difference between the exodus of this year and the exodus of last year, at the same time there is a slight difference, and I understand there is a slight difference in the degree of stringency of the plague measures, to the advantage of the present period; the measures are not quite so stringent now?—They are not carried on in the same way. There were certain measures adopted last year which which were very objectionable to the people.

26,562. How do you account for the exodus continuing, notwithstanding that the measures are not quite so irksome to the people? Do you think that the plague measures, or the plague itself, has had chiefly to do with it?—I think the best informants in Bombay will tell you that the exodus, so far as it extends to the lower classes, is very largely due to the reason I have given, namely, the annual reason—the harvesting, which calls for the return of a great number of people, who are cartmen, and porters, and mill hands, and so on, who have all got their agricultural interests up-country. Then the other reason which has come under my own notice to a certain extent, is that the higher class of people, among whom there is very little plague, but who are no doubt extremely sensitive—people who read the statistics every week in the paper, and get sensitive when a case comes near them—think that it is time to go, although they are not the class which gets plague. There is also some exodus due to the approaching hot weather.

26,563. Having regard to the facts which you have laid before us, do you think the exodus is chiefly to be accounted for by people wishing to avoid plague measures, or by people wishing to avoid the plague itself?—I do not think there is an exodus from Bombay now due to the people avoiding plague measures. There may be individual instances, but certainly not generally.

26,564. (*Mr. Hewett.*) Last year there was quarantine?—Yes.

26,565. You cannot compare the two years, because there was quarantine against Bombay?—Yes.

26,566. The people were not allowed to leave this place, unless they were segregated for 10 days?—Exactly. This year, although the gates are open, the exodus is extremely nominal. I do not think it is exceptional, except during the last week or two, and with regard to that, as I say, we have no statistics of previous years to set against it, but there is always a hot season exodus. I said the other day to some of the high class families in Bombay who were leaving here, and taking their wives and children to the extent of 22 or 23 members each, when they came to me to get letters of introduction—"Why are you going away?" and they said—"We go every year as the hot season comes on." They would not admit that they were running away from plague. They said, "If we had "been running away from plague, we should have "gone two months ago, or at all events a month ago, "but we have stayed right through the epidemic. We "believe the epidemic is now nearly over, but the hot "season is approaching and we are off." Whether that is true or not, I do not know, but I do not attach much importance to the exodus. I thought it would have been four or five times what we can show from our statistics.

26,567. (*The President.*) Then there is a reduction in the number of people who are entering Bombay?—Yes.

26,568. What do you think is the probable cause of that reduction?—The fear of plague. It is natural that people would not go to a town where there was an epidemic. That fear did not exist so much in the early days. I think that fear is growing on the people—the fear of going to an infected town.

(Witness withdrew.)

(Adjourned to London, *sine die*.)

At The India Office, London.

SEVENTY-FIRST DAY.

Saturday, 6th May 1899.

PRESENT:

Prof. T. R. FRASER, M.D., LL.D., F.R.S. (*President*).
Prof. A. E. Wright, M.D. | Mr. A. Cumine.
Mr. C. J. Hallifax (*Secretary*).

Surg.-Gen. C. Planck.

6 May 1899.

Surgeon-General C. Planck called and examined.

26,569. (*The President.*) You have retired, I think, from your appointment of Superintendent-General of Vaccination and Sanitary Commissioner in the North-Western Provinces and Oudh?—Yes, I served for about 20 years as Sanitary Commissioner and Superintendent-General of Vaccination in the North-Western Provinces and Oudh and retired in 1886—13 years ago.

26,570. You have prepared an interesting Report upon Mahamari, which we propose to print in the

idence*?—Most assuredly it is at your service. My sire in writing that Report was to record the facts ted at the time of inspection, unprejudiced by ieory.

26,571. We will assume that that is taken in, but ere are a few questions we wish to ask you in ldition.

26,572. (*Prof. Wright.*) I would like to know more the conditions of the people who infect themselves visiting plague houses, as I believe they do?—So has seemed to me.

26,573. I am anxious to know whether these people ear shoes or stockings?—The heads of the villages, uch as the Padhan (Headman) do wear shoes, but the oor people have no shoes. The poor people go about their naked feet. I never saw a poor man with shoes, o the best of my recollection; they would not dream f shoes—they have no men to make shoes. My expeience of the disease was gained in isolated villages far way from civilisation. The value of my report, to my ind, lies in its proof that plague was in India long efore the existing great trouble arose. The same isease was in Kamaun and Garhwal as now prevails in he plains, without apparent differences. Some medical uthorities inclined to the opinion that the disease was severe form of typhus, but that, I think, was a mistake. It was true plague and could not be otherwise amed in English. With reference to the present outreak in the plains, of course there seems to be a uspicion that it may have been imported to the plains y some person or goods coming down from the Hills. But there is a considerable traffic by ships and junks etween Hong Kong, where plague prevails, and Bombay, and that seems to me the more likely route f plague introduction to the plains of India.

26,574. Is there any traffic between Garhwal and Thibet?—In the spring and summer people are passing o and from Hundes, a country in the neighbourhood f Thibet; they travel across the passes when the snow melts, especially many flocks of sheep laden with borax n small bags accompanied by men and women (*see* para. 222 of the Report)*; most assuredly they would be in contact with people on the other side of the Himalayas. I do not know whether there was a prevalence of plague in the Himalaya mountains beyond British territory, but there was in China, in Yunnan itself, as mentioned in the last paragraph of Dr. Watson's Report.* Yunnan is a country of great extent, but part of it is on the China side of the Himalaya mountains.

26,575. Do you think the outbreak of plague in Garhwal might be due to this cause, or do you think the germ lives in the country?—I think the germ lives in the country of Garhwal and Kamaun. I think from the statements of my report, small in degree as they are and, perhaps, unimportant from the present extending view of the disease that plague broke out in the villages which I inspected in this way. It was generally a child or a woman living almost continually in the house who first suffered, and the cause of the disease seemed to be in the house itself. With regard to preventing the people from remaining in their habitations after plague has attacked a member of the family, I think you will find that when plague becomes well-known in the plains of India the people will flee out of their houses of their own accord. I have been 32 years in India and I never heard of a case of plague in the plains of India in all that time, so that the plains people know comparatively little about the disease yet. I believe you will find that if plague goes on for two or three years, the relatives of the sick person will flee away and leave him in the house. They will vacate their habitations. Plague has existed in Garhwal and Kumaun probably for centuries. By the present native generation it was supposed to have been commenced as a manifestation of God's displeasure, owing to the incorrect, or new, method of performing a certain religious ceremony by the then head priest (*see* para. 45 of Report).* Of course these unusual ceremonies had nothing to do with the outbreak of plague. It must be due to a specific microbe or some hurtful influence of that character (para. 248).*

26,576. Do you find that people may go on having plague when they do move out of their houses?—Yes, they would carry away the disease with them to the hut in which they lived on the hill side. That was not a frequent occurrence, but it did so happen occasionally, as the histories of the Report* show. As a general rule, the re-appearance of the disease amongst the people who had vacated the family home, arose out of the return of a number of the family to the home to fetch grain or other food, or to house cattle at night. The people, when they vacated their homes, lived in temporary huts, high up on the mountain side, or in caves. The disease seemed to be in the houses, and the people knew it, for in some instances, they tried to persuade me to burn their houses, and even burnt them of their own accord (para. 262).*

26,577. Are there many rats in this part of the world?—There are many delicate grey rats, but different in appearance to the rats of Europe.

26,578. Was the mortality among rats always noticeable in plague epidemics?—Not always. The rats I saw were grey in colour, rather squirrel-like, and about as long as a man's hand. As a rule, the death of rats in a house seemed to presage the appearance of plague disease *de novo* there, where rats had not died the outbreak of plague disease in the house appeared to have resulted from contagion. The rats did not seem to me to have died from poison, but from suffocation (para. 254).*

26,579. Did you see any rats dying?—No.

26,580. You did not observe that they died a very long lingering death?—No, they were found dead on the floor at night among the sleeping people.

26,581. Did you find many mild cases of plague occurring in association with these severe cases?—I do not think there were many mild cases. I had a history of 240 cases, and only 17 cases recovered, so that they must have been severe, as a rule.

26,582. Do you think that buboes are familiar objects to the people of these parts?—Syphilitic buboes do you mean?

26,583. No, I mean generally, are the people accustomed to suffer from mild buboes, or is a bubo a rarity in these parts?—I should say that syphilis is rather prevalent among them, and I should suppose buboes would be, but Medical Officers of Dispensaries know more about buboes of that character.

26,534. You have never been up in these Hills except in plague times?—I have been there for 12 years on and off.

26,585. If cases of mild bubo occurred there, would they have come under your observation?—No. I know that syphilis is very prevalent in the Himalayas, but I do not think there can be any doubt about the plague disease I saw, because I examined patients, and they had a temperature of 105 to 110, the pulse at 120 and 130, and some died in 12 hours after the attack commenced, and then no buboes were visible.

26,586. I do not think you noticed in your report congestion of conjunctivæ as a sign of plague?—No, it is so long ago, that I do not remember it. It was not likely that I should have noticed it if it had existed. At para. 117 of my report, the eyes were seen to be "suffused." I think that points to congestion of the conjunctivæ. But I cannot be sure now. I certainly did not make a point of looking for conjunctivitis. Generally, the patients eyes were closed.

26,587. Have you noticed that in their delirium, the people were inclined to wander about?—Yes, and fall down, or throw themselves down into the ravines. There are one or two cases recorded in my report that so ended in death.

26,588. I understand you to say that the grain did not seem to cause any infection?—No, I think not, Dr. Watson thinks it did, as recorded in his report appended to my own report.* I do not think you will find plague disease is due to any hurtful character of the grain consumed, but to something much more serious than any unwholesome food. I am quite sure the people will flee away from their homes if the plague continues to prevail in the plains of India. They will leave their sick friends and flee away as from certain death. It was so with regard to this plague, or Mahamari, in Garhwal and Kamaun. The prevalence of the disease was not known to the authorities for some time, until at last the Commissioner of the Province noticed that the people suddenly left their homes, and inquired as to the reason for this unusual flight. "Mahamari" is not the native name for the disease to avoid which they fled away. Mahamari means any deadly form of

* *See* App. No. XXV. in Vol. II. of these Proceedings.

Surg.-Gen. C. Planck.

6 May 1899.

disease. "Gola-Rog" is the correct local name for plague, its exact translation being "bubo-disease." "Rog" is the Sanskrit word for disease, and "Gola" for bubo or boil. Any epidemic form of disease, for example, cholera, is called Mahamari during its prevalence (*see* para. 245).* The Civil Officers of the Government, recorded the term "Mahamari" as the native name of the disease, hearing it so spoken of. But the true native name of the disease is as good a definition of plague disease as any yet recorded, I think. Anyway, its fairly accurate translation as "Plague of Boils" is strangely in accord with the sacred record of the disease from which Egyptians had to suffer in the time of Moses.

26,589. Did any epidemic come under your observation where the mortality was comparatively mild?—I have seen no other cases, except those which are mentioned in my report. There were comparatively few deaths in any one village—about, at most, 14 or 15. This I attribute to the fact that the people vacated their homes quickly, taught by experience. Absolutely all my knowledge in regard to plague disease in Garhwal and Kumaun stands recorded in my report* which is to be printed in evidence.

* *See* App. No. XXV. in Vol. II. of these Proceedings.

(Witness withdrew.)

Surg.-Col. J. Richardson.

Surgeon-Colonel J. Richardson called and examined.

26,590. (*The President.*) I believe you have served in the Vaccination and Sanitary Departments of the North-Western Provinces of India?—Yes. I have served for over 30 years in India.

26,591. Will you tell us between what dates you served?—I entered the Service on the 27th July 1859, and left on the 19th May 1894.

26,592. And you have had some opportunity of observing the disease which resembles plague in Kumaun?—I have.

26,593. (*Mr. Cumine.*) On how many occasions had you that opportunity?—Only two occasions that I can distinctly remember.

26,594. Did you see many cases or few?—I saw few.

26,595. Had you any opportunity of watching a case from its beginning to its close, or making a *post mortem* examination on the body of anyone who had died of this disease?—No, I had not.

26,596. In what years did you visit Kumaun?—In 1884 and 1886; but I visited Chaudans in 1876. I did not see plague there, but I was in a village from which the people had just fled on account of the plague, and I saw dead rats there. That is the only material fact I can remember in connection with it.

26,597. Will you describe your first visit in 1884?—When I reached the village of Liti near Shama, on the way to Tejam, I found the place deserted and partly burnt down. The inhabitants were living in shelters at some distance from the village. I could get none of them to enter it with me. In one house I discovered the dead body of a young man, of about 20 years of age, in a sitting posture, resting against the wall. Death had taken place too long previously to make it possible for me to come to any conclusion from the examination of the body as to the cause of death. The mother of the lad came to within about 100 yards of the village; and, with tears, told me of her son's illness, and of his death from gola or phutkia. She said she was not allowed to stay with him or to go and see to the disposal of his body. None of these people spoke of mahamari, only of gola or phutkia.

26,598. How did they describe the disease to you?—As a fever which began like an ordinary fever, but which speedily became violent, depriving the patient of sense and proving fatal in from two to three days.

26,599. Did the people who developed swellings in the groin or armpit seem to have a better chance of surviving, or a worse chance?—They did better because they lived longer. They did not develop swellings until some days had passed. Those of the sick who survived for a longer time showed swellings in their groins and armpits.

26,600. In this case was there any history of the death of rats in the village before or during the outbreak?—There may have been, but I cannot remember.

26,601. Will you describe to us your visit in April 1886 to the village of Bargaon?—I remember all the salient features of my visit there, but I do not remember the details. In April 1886, I visited the village of Bargaon in Kumaun, near the road after it crosses the Ramganga leading into Garhwal. The village had been evacuated by the inhabitants excepting by a man who was ill with gola, and too weak to move. This man had swellings in his groins, and was suffering from fever, but was quite sensible, and was in hopes of getting well. The swellings, he said, were getting smaller; there certainly seemed no tendency to suppurate. A relation came and placed food and drink by him, and he was attended to by a Hospital Assistant from the Ganai Dispensary. Some of the other villagers had been ill but were recovering; they were living in the vicinity of their village, although they did not enter it.

26,602. How did the villagers say the disease began in this place?—They said it began as the ordinary kind of fever—they called it sanjar—which is not uncommon in the Hills. It becomes contagious, I believe; anyway, it prevails in an epidemic form in villages, but it is unaccompanied, so far as I know, by bubonic enlargements.

26,603. In this case, after the sanjar had gone on for a little time, did they notice that anybody had a swelling in the groins?—They did. The account they gave me was that when they were carrying one of their number down to the little stream below, to burn the body, they noticed swellings in the groins, and they hastily threw down the body. I think the Patwari told me it had been eaten by jackals. Anyway, it was thrown down and the people cleared out of the village.

26,604. When they discovered the swelling in the groin did they say: "We were wrong in supposing it "to be sanjar; it turns out to be something else"?—That was their belief, that the disease which they had in the first instance thought to be sanjar was actually gola. They did not imply that the disease grew from sanjar to gola; that was my own idea, not theirs. They said that at first they believed it was fever, and seemed to think it was ordinary sanjar, severe form of fever, something of the nature of typhus. Then when they were taking this body down to be burned, after several had died of the other disease, they discovered these swellings, and said they had made a mistake and that it was a more severe form of the disease. I will not say they said that—I made a mistake—because they did not connect the two. They said it was gola. I never heard them make use of the word "mahamari." They threw the body down and cleared out of the place. They were not afraid of the first disease, but with regard to the other one they said: "This is the real "'golarog' which will kill us all," so they left.

26,605. Did you understand that golarog and sanjar were distinct diseases, or that golarog is merely a severe form of sanjar?—I did not gather from their account that they believed the diseases to have any connection. At least they did not express it to me, and I never heard them say that the two diseases were identical.

26,606. Did you observe anything which showed that a house remained infected after the people had abandoned it?—They told me that one man had died after the village had been evacuated by all the people, and that this was a man who went back to fetch some grain, or flour, out of his house. After the visit to his house, he contracted the disease and died. That is the account they gave to me; it is not what I saw.

26,607. In this village of Bargaon did the people tell you anything about the death of rats?—I cannot remember that. Probably they did, but I could not say they did. I am speaking from memory.

26,608. Ten years before that—in 1876—when you visited Chaudans in Eastern Kumaun, had you been shown any dead rats?—The village at the time was empty; but a man who belonged to the village came round the village with me, and showed me some dead rats. He said: "These have been dying about here; "they died before the outbreak of this phutkia."

26,609. You saw several villages in which golarog had been prevailing in 1876?—Yes.

26,610. Did you see any cases yourself?—No, I did not.

26,611. What is the character of the dwelling-houses in that part of the country?—The dwelling-houses are generally dark and ill-ventilated. One had almost to enter on hands and knees, and could scarcely stand upright after entering. These rooms, or rather garrets, were crowded with baskets of grain, baskets of wool, and goatskin bags of flour, wooden vessels filled with ghi and other domestic belongings; usually the cattle occupied the ground floor underneath these garrets or lofts.

26,612. Is that general?—That is pretty common, I believe; that is not confined to Chandans alone.

26,613. Have you seen any cases of the plague which is now prevailing in the plains of India?—Yes, I saw them in a cursory way in a hospital at Sholapur—about 18 or 20, so far as I remember.

26,614. From the cursory examination which you were able to make, did the disease appear to you to be similar to the one in Kumaun?—Most distinctly. I would not say it was identical. I did not enter into an examination of the cases sufficiently to entitle me to express a decided opinion.

26,615. (*Prof. Wright.*) Was the plague of mahamari spoken of by the people there as a familiar thing, not quite a new thing?—As a familiar thing. They seemed to be quite accustomed to visits, if not in their own villages at any rate in other villages about. They did not speak of it at all as a new thing. They were very much afraid of it; but it was not a thing that came upon them as an unexpected calamity.

26,616. They are familiar with both sanjar and golarog?—Yes, they are familiar with both.

26,617. Do you think the outbreaks in this district might be caused by importation from the far side of the border?—I would not say what is possible or impossible; but it struck me that it might be that the disease may have originated in this way. I suppose you must have germs before they can live, but the conditions were such in these houses as certainly to encourage the development of contagious fever of the nature of typhus. That was the idea we all had for many a day.

26,618. You thought the local conditions were sufficiently bad to account for the disease without any theory of importation?—It might have been imported from time immemorial, and the germs may have remained there in a latent condition. They may have become excited by the excess of those conditions favourable to their development.

26,619. Do you know if the people in this district wear shoes on their feet?—The wearing of shoes is, I think, chiefly determined by the part of Kumaun dealt with—low down in the warmer parts they are, as a rule, not worn; high up near the snows both shoes and socks are often worn. The people do not always wear shoes, I allow; they do not in the summer time any way.

26,620. Cases came under your observation where people got plague from re-visiting their houses after the houses had been evacuated?—Yes, I have heard repeatedly of that.

26,621. In cases of that sort, did the people who returned to their houses wear shoes, or did they go about barefooted?—I cannot say, because I do not remember.

26,622. You do not know what the habit of the country is?—I know the habit of the country well.

26,623. Is it the habit to wear shoes, or to do without them?—The majority of them do not wear shoes. The coolie people and the labouring classes, who form the bulk of the poor people of the community, do not wear shoes as a rule.

26,624. Not even in winter?—That I do not know; I have not been there in winter, but I think not. The better classes nearly always wear shoes with a sort of woven woollen uppers and leather soles. The "uppers" are usually made of woven woollen bands.

26,625. Do you know what their sleeping quarters are like, do they sleep on the ground?—They sleep in the lofts; in the upper storeys.

26,626. Do they sleep on the floor?—Yes, they do not have beds. I have never seen anything in the way of beds in most of the places I have been in. The people sleep just on the boards on the loft or garret in which they live. Some live in the lower storeys.

26,627. What are the floors made of in the upper storeys? Is the upper floor a boarded floor?—Yes.

26,628. Is the floor bare boards, or is it covered with cow dung?—I do not think I saw that; it was very dark. In the lower storey, probably, they have cow-dung floors.

26,629. (*The President.*) There is much cow-dung in the lower floors?—Yes; they were generally covered with it; the cattle lived there.

26,630. A foot or two of cow-dung?—Perhaps so; until the season came when they carried it out in baskets and put it in the fields.

26,631. In the upper floors, what were the means for ventilating the rooms?—The ventilation found its way between the slates. They were mostly covered with big, coarse, thick slabs. There were bits of holes now and again, in which they stuffed something, as a rule. They were very ill-ventilated and dark places. I remember particularly about the darkness—you knocked your head against the baskets and things when you went in. They were pent-roofed, as opposed to flat-roofed, affairs.

26,632. (*Mr. Cumine.*) I understood you to say that they regard the two diseases, sanjar and gola, as separate?—They did not seem to do that.

26,633. Therefore, they might regard one as a familiar thing, and the other as a new thing?—They were familiar with both.

26,634. (*The President.*) Perhaps the difference they particularly attended to was that one was a dangerous disease and the other was not?—The other was not so dangerous. I think, that is the feeling.

(Witness withdrew.)

Surgeon-General James Cleghorn, I.M.S., called and examined.

Surg.-Gen. J. Cleghorn, I.M.S.

26,635. (*The President.*) You are a retired Surgeon-General?—Yes.

26,636. You have lately acted as Director-General?—Yes.

26,637. You are able to give us an account of the measures which were adopted in connection with plague throughout India, which came under your official knowledge, from 1896, until you left India?—Yes.

26,638. That evidence is in your printed statement which you put in?—Yes, it is as follows:—

[*This Note must necessarily be incomplete, as some time has elapsed since my departure from India, and I have not now access to the office records.*]

In August 1896 a peculiar form of fever, of a fatal type, was observed by some of the medical practitioners in the City of Bombay. In some instances it was accompanied with glandular swellings, and in others with pneumonic symptoms; but none of the observers had apparently seen a similar disease before, and they naturally hesitated regarding the diagnosis. A death was said to have been registered on the 31st August as having been due to "bubonic fever," and on the 23rd September, Dr. Viegas, I think it was, who reported to the Municipal Commissioner that plague was present in the City. Others, however, doubted the correctness of the diagnosis; but on the 29th September the Government of Bombay telegraphed to the Government of India, that the Surgeon-General of Bombay had reported having seen 20 cases of plague, all of a mild type. On that date the Government of India telegraphed to Mr. Haffkine, then on cholera inoculation duty, to proceed at once to Bombay, and report to the Government of India his opinion, after having made a thorough bacteriological examination of cases He reported, on the 13th October, that the disease was undoubtedly plague.

Although no deaths from plague appear in the mortuary returns for September, yet, on the recognition of the disease as plague, its presence was discovered in nearly all the quarters of the City. The disease at first spreads slowly and irregularly, and its

Surg.-Gen. J. Cleghorn, I.M.S.

6 May 1899.

diffusion in October showed, I think, that cases of the disease must have existed for some time previously.

In the latter end of September the Government of Bombay appointed a Committee, composed of official and non-official medical members, with Mr. Snow, the Municipal Commissioner, as Chairman, to advise the Municipality as to the measures which should be taken towards stamping out the disease, and improving the sanitary condition of the City.

Acting on the advice of this Committee, Mr. Snow, on the 6th October, issued a notice to the inhabitants, making provision for the removal to hospital of all plague patients, and for the evacuation—compulsory if necessary—and disinfection of all houses in which cases had occurred. A hospital was opened in Arthur Road for the reception of cases, and huts were erected for the isolation of individuals who were liable to infection.

These proposed measures gave rise to great excitement among the population; large numbers left the City, and crowds assembled round the hospital, threatening to destroy it and assault the staff. The conservancy staff of the Municipality became disturbed, fears were entertained that they also would leave the City, and thus put a stop to the ordinary cleansing of the town and to all sanitary work in connection with the plague.

The cases of plague being at the time few in number, and the disease showing little or no tendency to increase, it was considered advisable, in view of the popular excitement, to modify the measures published on the 6th October. The Health Officer was accordingly instructed, on the 16th October, not to remove patients living in houses where they could be isolated and properly attended to; and on the 30th October rules, modified in this direction, were published for general information. Hospitals were at the same time established by private individuals for the treatment of cases belonging to different religions and sects; but they apparently failed to attract patients.

In the meantime, the large staff of officers and subordinates employed by the Municipality worked most vigorously in cleaning and disinfecting houses, improving and extending the drainage, and in attending generally to the sanitary wants of the City.

All their efforts, however, failed to check the progress of the disease, and, as the Government of India could not, from the details received, clearly appreciate the actual state of affairs, or satisfy themselves as to the extent and efficiency of the measures adopted, I was directed to proceed to Bombay and make myself acquainted with the facts. I accordingly left Calcutta on the 4th January, arriving in Bombay on the 7th. In company with various Municipal officials I visited different localities infected and inspected a large number of the houses and rooms in which cases had occurred. These houses had distinctive marks on the front wall, showing the number of deaths and cases which had occurred in each, so that there was no difficulty in recognising them.

I was much struck with the enormous amount of work which had already been done by the officers serving under the Municipality, but I at the same time realised that the situation was, as regards the prevention of the disease, a hopeless one, unless the scheme was made more comprehensive. The incidence of the disease showed that it had chiefly appeared in the worst houses, and that the better ones, including the small hotels situate in the infected quarters, had practically escaped.

I had, of course, a considerable experience of the conditions under which the poorer classes in other parts of India lived, but I had never seen anything so bad as existed in the chawls of Bombay.

After I had made myself fully acquainted with the condition of affairs, I invited the leading medical practitioners, both official and private, and the various experts, to meet me and discuss the question at the office of the Surgeon-General. Their views, as published on page 288, Vol. II. of "The Plague in India" compiled by R. Nathan Esq., C.S., I submitted to the Government of India, and strongly recommended that they should be adopted and acted upon. This was done and the measures enforced by the Government of India were in future based on the following lines:—

1. Early detection of cases.
2. Segregation of the sick and their treatment in suitable hospitals.
3. Removal from infected localities of those liable to infection, and their segregation.
4. Disinfection of clothes and other articles liable to infection.
5. Disinfection of houses situated in an infected locality.
6. Enforcement of general sanitary measures.

The authorities in Bombay were, however, so impressed with the local difficulties attending compulsory evacuation and providing temporary accommodation for the segregation of the people removed, that little was done in this direction.

I left Bombay on the 13th January, arriving in Calcutta on the 16th. After clearing off the more important arrears in the office, I left for Karachi on the 22nd January, arriving there on the 26th, but was only able to remain there until the following evening, as I was ordered by the Government of India to proceed to Venice, as delegate to the Conference on plague about to assemble there.

The steps being taken at Karachi were in accordance with the views of the Government of India, and under the direction of Mr. (now Sir) A. Wingate, they proved ultimately successful. No force was employed to move the people into huts. It was accomplished in time by the personal influence of the officers, assisted, no doubt, by the fear created by the presence of plague.

I arrived in Calcutta on 31st January, and left for Venice on 4th February, and reached Venice on 20th February, some days after the opening of the Conference.

Quarantine was in force both at Brindisi and Marseilles. As a delegate, I was allowed to land at the former port, but the steamer with the other passengers had to proceed direct to England. While in Venice I succeeded in obtaining the intervention of the delegates from Italy and France towards removing the quarantine.

I had, while in transit, prepared a note on the characteristics of the disease as presented in the outbreaks at Bombay and Karachi, its progress up to date, and the measures taken by the Government for controlling its spread both by sea and land. The note was read at the Conference, and the information furnished appeared to satisfy the delegates that the Government of India were taking every precaution to arrest the progress of the disease, and in preventing its spread to other countries. The results of the Conference were, from the Government of India point of view, satisfactory.

After reporting to the Secretary of State for India, I returned to Bombay in April. On arrival there I found that plague operations in the City of Bombay had been entrusted to a Committee, of which General Gatacre was President. I had the advantage of being taken over several of the hospitals by him, and of learning from him the organisation in force.

The objects the Committee had in view were:—

1. The discovery of all cases of plague.
2. The treatment of all cases in hospitals.
3. The gradual segregation, as far as possible, of the probably affected, that is, of those living in the same room with, or in close attendance on, persons suffering from plague.

The work of the Committee also included all sanitary measures, the disinfection of houses, and the destruction or alteration of those considered unfit for habitation.

The removal and segregation of those liable to infection were not carried out on any extensive scale, or in the manner desired by the Government of India; but the organisation, and the methods employed for carrying out the other objects, were of the most complete and perfect character. Except at first, little or no opposition was experienced, and General Gatacre, by his tact and great personality, carried the whole population with him.

On leaving Bombay I took over charge of my duties at Simla. All papers and questions regarding plague were passed on to me for information and remarks, and the necessary orders were issued by the Government of India. With further experience the rules were elaborated, and, in some instances, modified to suit local conditions; but the main principles, as previously laid down, were invariably adhered to.

The reserve of officers on special plague duties was fully utilised. Many officers were removed from their ordinary appointments, and placed on plague duty. In the case of outgoing steamers and craft from Bombay harbour, all the crews and passengers were inspected by

ne Port Health Officer, who was assisted by a staff consisting of an additional Port Health Officer, three Commissioned Medical Officers, three Military Assistant Surgeons, one Hospital Assistant, and two lady doctors. When the stress of work was great, or when time was of importance, the Port Health Officer obtained further help from the medical staff engaged in other duties in the city. The work thrown on these officers was exceptionally heavy, and the thorough manner in which it was performed was proved by the results.

Posts of inspection, numbering 221, were gradually established on the different lines of railway, at the principal stations and junctions. Forty-six of them were under the charge of Commissioned Medical Officers. Huts were erected at a large number of the stations for the treatment of the sick, and for the segregation of suspects. There were altogether employed entirely on plague duty 64 Commissioned Medical Officers, 41 of whom belonged to the Indian Service, and 21 to the Army Medical Staff; 20 private practitioners; 31 Military Assistant Surgeons; 36 Civil Assistant Surgeons; and 211 Hospital Assistants; besides a number of lady doctors and nurses. Other officers and subordinates, holding regular appointments, always assisted when their services were required.

So far as I can remember, no complaints were received by the Government of India as to the manner in which these officers discharged their duties, except in two instances. One was with regard to a native of India, who was a member of the Indian Medical Service; the other concerned a Military Assistant Surgeon.

In addition to the above, there were employed on sanitary duties 45 British officers, 16 native officers, and 1,617 non-commissioned officers and men.

The additional requirements for medical officers for famine and war proved too great a strain on the two medical services, and in July or August private practitioners were obtained from England for plague duties.

In October, a Commission, consisting of Sir A. Wingate, Surgeon-Colonel Hay, and myself, was appointed by the Government of India to visit the places in the Bombay Presidency attacked with plague and to see how the operations were being carried on. I left Simla on 1st November, and visited alone, or with the other members, nearly all the infected localities. The objects of the measures and the manner of execution were carefully explained to all the officers concerned, and our visits were much appreciated. It was difficult for local officers to grasp the object of written orders on such a complicated subject. Inspection of travellers at the different stations was rendered more complete, and means of disinfecting clothing by steam were introduced at appropriate stations. Local measures were introduced on a systematic plan. Our recommendations with regard to each place were forwarded to the Governments of India and Bombay.

On my return to Calcutta on 24th December, I drew up fresh instructions regarding plague administration for the general guidance of district and other officers, which embodied the results of the experience gained on the tour. This note was circulated to all local governments and administrations for information and guidance, with the Government of India Resolution, No. 227—240, dated 3rd February 1898.*

The large amount of extra work, both clerical and inspectional, thrown on me by the plague, proved too much for my constitution, and on my return from the Bombay tour, I felt unable to continue in office. With the consent of his Excellency the Viceroy I left India in March.

26,639. I think there are only a few questions which we have to ask you?—I gave everything I could think of in connection with the administration of plague, and the different measures which were adopted.

26,640. You often visited Bombay and Karachi and the other important towns and districts which were affected with plague?—Yes.

26,641. And you were impressed with the insanitary condition of some of these towns and districts?—Yes, the condition is common to all Indian towns.

26,642. You thought that insanitary conditions were specially prevalent in Bombay, I think?—Yes, in the houses.

26,643. You do not refer so much to the general conservancy as to the houses?—That is so.

26,644. You thought that these houses were, in that respect, worse than those of Calcutta?—Worse than any place I had seen, owing to the enormous number of people who lived under the same roof. I have never seen anything like such overcrowding. In a place, probably, the length of this room—6 feet by 12 feet—I have seen the floors covered with people lying down, and in addition, beds hanging from the roofs on which other people slept at night. There was absolutely not one ray of light or any means of getting air to these rooms. We had to strike a match to see the opposite walls, because it was so dark, and that was in the middle of the day.

26,645. I suppose the ceilings from which they suspended their beds were not very high?—No, they were not. I have never seen anything like such overcrowding in rooms absolutely without any means of ventilation. All the windows, when there were windows, were closed with rags and remnants of bedding.

26,646. Where these windows existed, I suppose they were not large?—No, not in all cases.

26,647. In many cases they opened into a narrow space?—Yes, on to the wall of another house.

26,648. Where the air was necessarily foul?—Yes, the drains in the alley between the houses were open, and the passages were just wide enough to allow the sweepers to get up to sweep the drains, therefore, to ensure privacy from the inmates of the next house, all the windows were covered up with clothing, &c.

26,649. Is it within your knowledge that plague was specially prevalent in these places?—Yes, especially in these insanitary houses. I gave a description of these chawls in a note I submitted to the Plague Conference in Venice. I have not quoted it in my evidence. It is in Mr. Nathan's compilation. I have given a précis of it in my evidence.

26,650. You have given a précis of it in your evidence, but a fuller description will be found in Mr. Nathan's compilation?—Yes.

26,651. Your refer to several alterations which took place in the measures which were adopted to meet plague at different periods and times?—Yes, as our experience increased, and as the difficulties presented themselves to us, the rules were elaborated—the complete rules which were ultimately accepted were those issued by the Government of India to local governments.

26,652. Numbers 227–240?—Yes. That gives the complete rules. We acted on those rules previously, but they were elaborated so as to meet the work which the district officers had to contend against.

26,653. These were issued in February 1898?—Yes.

26,654. But there were also modifications which were not so much dependent on the reasons which you have given, but upon the difficulties in carrying out proposed regulations?—Yes, but it was after my trip with Sir Andrew Wingate through the plague-stricken districts that we thoroughly realised what these difficulties were. It was impossible sometimes to carry out certain rules.

26,655. What was the nature of the difficulties?—There were difficulties with regard to preventing people in infected districts getting out of the districts, not by railway, but by country roads. You could not have possibly controlled all traffic. The local officers knew exactly the local conditions and were advised to act according to circumstances.

26,656. Were not there difficulties also due to the opposition of the people themselves to certain steps which you wished to be carried out?—We never had serious opposition after the plague was fully established, so far as I can remember. With a good local officer there would be few difficulties. If a local officer took time to carry out the measures and got the leaders of the people with him, there was little difficulty. In Surat, for example, there were 20,000 people in huts in different camps, 4,000 or 5,000 in each camp, and there was not the slightest difficulty there. The officer in charge was possessed of tact, and had great influence with the people, and he carried them with him.

26,657. It was the personality of the man?—Yes. I heard there was opposition on the Great India Peninsula Railway line in the villages, and there was opposition in Bombay City at first.

26,658. In what way did that opposition show itself?—They absolutely refused to allow the removal of the sick, or to evacuate the houses in which the sick were Mr. Snow then modified the rules.

* Not reprinted with the Proceedings of the Commission.

Surg.-Gen. J. Cleghorn, I.M.S.

6 May 1899.

26,659. To what extent?—He did not remove the people from the infected localities.

26,660. Was it made optional with the Health Officer?—Yes.

26,661. After proper isolation?—If proper isolation could be made and the patients could be properly attended to in their own houses they were allowed to remain there.

26,662. And with regard to contacts and the people in the neighbouring houses, they did not attempt to do anything with them at that time?—No; I do not think so. It was never completely done in Bombay. Evacuation was never carried out on the scale necessary to make the measure thoroughly effective.

26,663. Do you think it was an impossibility?—The local officers and the local government said it was an impossibility.

26,664. They have now, however, established a very large number of camps in Bombay to which people are removed?—They did, for a time, before I left—there were camps then. It was said there was not enough space, but there are open spaces in Bombay. There were places in the immediate neighbourhood where people could be taken by train. Of course it means a great organisation and expense, but the point was that here was a disease in Bombay City, and that the whole of India was imperilled, and the commercial relations of the city seriously affected for the time being, unless the plague could be exterminated in Bombay. The feeling was that, with so much at stake, it was really worth while acting on the rules which were considered advisable, notwithstanding the great expense which would necessarily be incurred.

26,665. At first, in several large towns, not so much, of course, as in Bombay, there was, undoubtedly, a good deal of opposition, I think?—As for instance?

26,666. I mean in every large town?—There was passive opposition.

26,667. Against segregation?—It was always, I think, opposition in a passive form.

26,668. Has that been got over?—That has been got over, to a large extent, by the tact, firmness and individuality of the officers concerned. Little or nothing was known about the plague in Sholapur until it was nearly all over the town. The early recognition of the disease is one of the difficulties, but eventually the whole place was evacuated.

26,669. But they had a difficulty at first?—Yes, a great difficulty. The inhabitants concealed the existence of cases.

26,670. Was there any fear of active opposition?—There is always that danger, as a very slight matter might develop it. In carrying out measures affecting the habits and customs of the natives there is always the feeling that opposition may be aroused, unless the local officer is conversant with the people and has gained their confidence.

26,671. From what you stated a moment ago, I assume that you think evacuation is a very valuable measure?—Yes, evacuation of a locality, that I am perfectly clear about.

26,672. You think it is the most effective measure?—Yes, it is I think, the most effective remedy, because the plague as I saw it was absolutely a disease of locality. What struck me going through Bombay was that none of the good houses were attacked, not even the small hotels where sailors and others lodged.

26,673. There was not plague even in those quarters?—No. The sanitary arrangements there were fairly good. I do not think that a single case occurred in those small hotels.

26,674. Was there plenty of light and no overcrowding in these houses?—That is so. They were like the dak bungalow arrangements in India, and the places were built according to European ideas. There was no overcrowding, of course.

26,675. Have you any instances in which evacuation was very successful? I suppose you have many?—Yes; when taken in time, and we have early intimation of the cases. Under those circumstances evacuation almost invariably arrested the disease. It was arrested at Chandausi, but it took some time, and also in Khandraoni, Dr. Crofts stopped the disease there at once. Its progress was also arrested at Surat and in Karachi. It took Sir A. Wingate weeks to get the people to leave the town.

26,676. What is the population of Karachi?—I think about 100,000. The evacuation of the town was a most difficult undertaking, and was carried out by sections. Sir A. Wingate worked very carefully. He built huts, acting, I think, under instructions from the Government of India, and he got one section of the town evacuated. Gradually all the people were located in huts, and the disease was arrested there for a long time. It was a very great undertaking indeed.

26,677. In a large place you think a great deal might be done by evacuation in sections?—Yes, it was always found that when the disease was reported in a village or a town, there were invariably cases found in the vicinity of those reported, so that it was not only necessary to evacuate the houses in which a case was reported, but also the houses in a certain area round about.

26,678. When you are dealing with a very large population, much, if not all, the benefits of complete evacuation may be obtained by evacuating the people in sections?—Yes.

26,679. There is almost no limit so far as population is concerned if they are treated in sections?—Except as to the accommodation which you can provide.

26,680. Supposing you can dispose of 40,000 or 50,000 people at one time, that practically comes to almost no limit, so far as the population is concerned?—Not if you have places in which to accommodate them and you have the organisation which is necessary. Of course, even then it is not so effective as complete evacuation would be when carried out in the case of a small community. But the only practical way to limit the disease is to get the people out of the quarter.

26,681. You may, at any rate, much lessen it, even if you do not altogether stop it?—Absolutely; that, I think, is perfectly clear.

26,682. In some of these cases referred to, such as Karachi and many other places where there has been complete success, the disease has again broken out on the people returning, and there have been two, three or even four outbreaks afterwards; how is that to be accounted for?—I should say it is on account of the construction of the houses, either by re-infection of new arrivals, or by the measures not having been thorough in regard to the cleansing and disinfection of the house. It was intended to destroy the worst houses but this was found to be impracticable.

26,683. After all this trouble in large towns—as in Poona, for example—has been taken and much expense incurred resulting in a successful suppression of the outbreak, if an outbreak occurs again because of infection from some other place, that shows that in order to eradicate plague altogether, it is very necessary that the other infected places should be treated in the same way, does it not?—Certainly.

26,684. If there be one infected place within probable communication, which is not dealt with in this—in your opinion—the only effective manner, then re-infection may at any time occur?—Yes.

26,685. And the work that has been done will be thrown away?—Yes.

26,686. With regard to this question of evacuation, I suppose you appreciate that the process of evacuation may itself sometimes extend plague by the people not being entirely in hand and running away to non-infected places?—That was one of the difficulties, and it was met by surrounding the section of the town to be evacuated, either with troops or police.

26,687. That may not be absolutely effective because people break the cordon?—They have done so, undoubtedly.

26,688. But even if they have done so, it is much better that the plague should have been reduced by the measures that have been taken than that it should have been left to itself or only inadequate measures adopted?—Yes. Evacuation of the locality was the first measure to be carried out. If those evacuated could not for any reason be properly segregated, the disease would doubtless in many instances be communicated elsewhere. Evacuation and segregation would, if possible, be enforced in the new centres. Latterly, when the disease first appeared in towns, the people were allowed to leave the place.

26,689. Your views are clear and decided, but have they been entirely carried out?—I think they have.

26,690. Did you make any special inquiry as to how plague was introduced into India?—Yes, but the results were not satisfactory; nothing authentic could be ascertained.

26,691. It was first introduced into Bombay?—Yes, the idea was that pilgrims from Garhwal had introduced it into the city. They came from Garhwal where mahamari was believed to be present.

26,692. How long does it take to travel between the two places?—It depends upon what part they come from. By the railway it would take three days and nights.

26,693. Do many pilgrims or other people travel from that district by railway?—They prefer to travel by rail. Any people who were going to Bombay would go by rail.

26,694. And you say they do go to Bombay?—Yes.

26,695. Therefore, an infected person might arrive in Bombay three days after leaving Garhwal?—No; because he has to travel down by road from Garhwal to the train. There was absolutely no clear evidence of its introduction from Garhwal.

26,696. How long would they take from the part nearest the railway to get to the railway?—A week or 10 days.

26,697. Before they reached the railway from the nearest part?—Not the nearest part, in Garhwal.

26,698. A week or so?—About a week. I do not know much about Garhwal. There were no reported cases of plague in Garhwal at the time.

26,699. It would take seven days to go to the railway alone?—Yes.

26,700. And another three days to go to Bombay?—Yes, it would probably take more than three days to go to Bombay, because the travellers would probably break the journey to prepare their meals, and, perhaps, visit certain holy places *en route*.

26,701. What do you think of the possible importation from China?—I think that it is a very probable source.

26,702. Have you any suspicion with regard to the Caspian Sea?—No, there is no proof of it coming in that way. We heard of no plague at the time, and there are no people coming from the Caspian Sea to Bombay, except Mecca pilgrims. There is constant traffic between China and Bombay.

26,703. Is there any direct communication between Calcutta and China?—Yes.

26,704. Assuming that China was the source of the infection, how do you account for Calcutta having been almost free from plague?—I do not know.

26,705. Have you had much experience of the effects of inoculation?—Only the returns sent by Monsieur Haffkine.

26,706. You have studied these?—I have. They were satisfactory so far as they went. They were considered so satisfactory that the Government of India directed the Government of Bombay to give Monsieur Haffkine every facility for carrying out voluntary inoculation.

26,707. Your experience may also have allowed you to come to some conclusion as to the efficiency of inoculation as a plague measure in stopping the progress of plague or extinguishing it?—It was hoped that these inoculations would, for a time at least, secure immunity to the individuals, and, if so, the progress of plague would, under certain circumstances, be arrested, or its virulence materially modified. Inoculations would then greatly simplify the measures adopted by the Government of India.

26,708. Supposing that inoculation failed as an actual measure for eradicating plague, what, then, would you fall back upon now—have you formed any opinion upon that?—With early information regarding the presence of the disease, evacuation, segregation, and the other measures adopted will prove effective: without such information, difficulty will always be experienced in the case of large towns.

26,709. You state that it seems to prevail very largely, if not chiefly, in the most insanitary quarters of the town?—Yes.

26,710. To what extent do you think the removal of these insanitary conditions might make plague impossible?—I believe that plague cannot appear and spread if the locality is in a proper sanitary condition.

26,711. Therefore, it would be the most effective of all measures?—Yes, the most effective. The Bombay Municipal Bill, if carried, should place that city in a good sanitary condition.

Surg.-Gen. J. Cleghorn, I.M.S.

6 May 1899.

26,712. That Bill would have to be extended to a large number of other towns?—Yes, to the whole of India, undoubtedly. I believe that the extinction of plague and the prevention of recurrence depends upon sanitation.

26,713. Therefore, you would hail, no doubt, with pleasure, any steps which could be adopted to permanently—not temporarily in a panic merely—but permanently and continuously uphold the sanitary condition of India?—Certainly.

26,714. (*Prof. Wright.*) Were you impressed with the infectivity of the plague in Bombay when you made this inquiry?—No.

26,715. Did you form an impression that the plague was not an infective disease?—I formed the opinion from personal observation and from the other sources of information that plague was not a very infectious disease, and that there was, practically, very little danger in visiting an infected locality or in attending on the sick.

26,716. You mean that the bacillus cannot pass from one person to another?—That is so under ordinary circumstances.

26,717. Then do you regard plague as infective only in the sense that tape-worm is infective? In other words, do you think that the plague bacillus becomes infectious only after it has lived for some time outside the body?—No, I do not go to that extent. I say there was no danger in going into an infected house—practically, no danger.

26,718. Then why do you propose to isolate the people and get the people out of their houses?—There is danger in the locality.

26,719. Do you approve of the sick man being taken out of his house?—Yes.

26,720. Then are you of opinion that the sick person is a danger to his neighbours?—There is a danger to other people in his expectorations.

26,721. Then a man may be directly the cause of infection to other people?—Yes, but not in the same sense.

26,722. I want to understand the distinction that you draw. Many are of opinion that the plague bacillus passes directly from one man to another?—I do not know much about that. We found that if a man scratched himself, or had an abrasion, and happened to get the bacilli there by handling the corpse at *post-mortem* examinations, or by opening the bubo, there was the possibility of his getting the plague in that way, or from the expectorations of the patient.

26,723. Does not that bring plague into the category of infectious diseases?—Yes, it is an infectious disease because it may be conveyed by the clothing. I never denied that it was infectious.

26,724. I understood that you differed from the general opinion in respect to that. In other words, I understood that you thought a man could not be directly a source of infection to other people?—Not in the same way as scarlet fever.

26,725. Not in the same degree you mean?—Yes. I said, practically, it was not infectious in that way, that is, you can handle the patients, but if you have a patient lying in a room expectorating there is danger in the locality. His friends must attend upon him. At one time I said, "All right, if there are these "obstructions to the measures, let the patient and his "friends live in the house and die there if necessary, "but get the other people out." Every thing has proved that it is infectious to a certain extent.

26,726. Do you think you have any means in India for getting information of the introduction of an infectious disease into a town?—It is absolutely impossible to get early information.

26,727. Do you think any measures ought to be taken for getting this early information?—Yes.

26,728. What measures? Do you recommend the use of search parties?—I recommend employing the natives.

26,729. Do you mean that the natives are to be paid as spies?—No.

Surg.-Gen. J. Cleghorn, I.M.S.

6 May 1899.

26,730. You mean that they are to be employed as voluntary agents?—Yes, we divide each town into sections and put them under natives.

26,731. Is that an efficacious manner of obtaining information of infectious disease?—It was the only method we could adopt at the time.

26,732. Do you think that infective disease will never be successfully combated until you get a system of death registration?—That is so.

26,733. And until you ascertain the causes of death?—Yes, but that is practically impossible.

26,734. Ought not that to be put in the fore-front of all plague measures?—Yes, but look what an enormous expense it would be; how could you do it? Where would you get the medical officers?

26,735. Do you think there would be any difficulty in ascertaining the cause of death in Bombay in a period when there was no epidemic—say, when the plague mortality declines in summer?—Yes.

26,736. Do you think there would be any difficulty in examining 60 corpses a day?—No, I do not think so, but the difficulty is in getting the report of the deaths; they are not always reported.

26,737. Do you think it would be possible to pass laws and make it penal to move or to dispose of corpses before they had been examined?—I think it would be very difficult to do that.

26,738. Do you think it is only playing with plague to attempt to deal with it without introducing corpse inspection? I am right, am I not, when I say that in Bombay they have been fighting plague for years and that they have not yet introduced that measure?—That is the cardinal measure, before sanitary and preventive measures if you can get it. Of course our difficulty was how we could do it.

26,739. Have you seen the system of corpse inspection worked in Poona?—No.

26,740. Have you seen it worked anywhere?—No.

26,741. In Karachi?—No.

26,742. Was it after your day that they had corpse inspection there?—Yes.

26,743. You do not recommend corpse inspection?—No.

26,744. Do you know whether corpse inspection has led to disturbances?—I think it was only applied in Poona as far as I remember, and the natives were utterly disheartened in Poona. The danger was in extending a measure of that kind to the North West Provinces and the Punjab. Up-country people would not stand it. Then, again, what would you do with a pneumonic case if you had corpse inspection?

26,745. Do you think corpse inspection might be assisted by bacteriological observations in cases of that sort?—Yes, but you are not supposed to touch corpses after the death ceremonies are performed. Before the washing process takes place you can do it probably, but you would certainly now and again get a person who would not allow you to look at the corpse, especially if it were the corpse of a woman.

26,746. Do you think that a provision for ascertaining the cause of death should be put in the fore-front of all regulations when it is a question of ascertaining when an infectious disease comes to a new town?—We could not do that. That would not be part of the scheme for ascertaining the cause of death.

26,747. You think that corpse-inspection ought not to be included in your scheme of discovery?—No.

26,748. You would not recommend any system of corpse-inspection or death registration as a plague measure?—I would have no inspection of corpses as a method of detecting the cause of death, knowing, as I do, the feelings of the people in regard to any such measure, but a system of death registration would be valuable.

26,749. You would rather go on under the present system?—Yes, with medical officers to certify to each death.

26,750. How do you propose to work the death registration without corpse inspection? Whose certificate would you take?—The certificate of a medical officer.

26,751. Do you mean a Commissioned Medical Officer?—Of any medical officer.

26,752. Would you take a native's certificate?—I would take the certificates of natives of a certain class.

26,753. Would you take the certificates of unqualified natives?—Not in that way, not for a perfect death registration.

26,754. Would you recommend, as a measure for fighting plague that a system should now be introduced which would ensure efficient death registration?—Yes. That is the principal thing, if you can show a practical way of doing it.

26,755. From your knowledge of India, do you think it would be impracticable to introduce a system of registration?—Our great difficulty was to obtain a report of deaths. Death registration is possible but hardly practicable in a country like India. It could be introduced into towns.

26,756. Do you recommend this as one of the essential things?—Yes, to get early information of the deaths.

26,757. There are many ways. Search parties is one way. Do you like that system?—No, I do not like that.

26,758. Do you think death registration is better?—Yes, if you can get it.

26,759. And in default of death registration you believe in inspection of the body?—Yes, certainly.

26,760. What certificates would you take as to the cause of death?—That of a duly qualified medical practitioner, either with an Indian or an English qualification.

26,761. Do you think you can trust the certificates of native practitioners?—I think you could trust the Assistant Surgeon class.

26,762. You would trust the medical certificate of a native?—I have always depended on them thoroughly.

26,763. Is it inconsistent, with what you know of the native practitioner, to suppose that cases of plague would be reported as measles, whooping cough, or something of that sort?—We get individual cases of that kind.

26,764. Do you think that that would be largely done?—I am inclined to place perfect confidence in the certificates of the Assistant Surgeon class.

26,765. You, then, would accept certificates only from the Assistant Surgeon class?—Yes, that is a very good class.

26,766. You would take their certificates?—Yes.

26,767. You would have to make some hard and fast rule, would you not?—Yes, but you get very good men amongst that class of local officers, and I think you could take their certificates.

26,768. Would you then propose to leave it to the discretion of the Medical Officer of Health to determine in each case what certificates he would take?—Yes, I would do that; I would make him responsible as he is the responsible officer, but I certainly would accept every certificate from the Assistant Surgeon class.

26,769. You would take every certificate from the Assistant Surgeon class as unquestionable?—Yes, until I found it was wrong.

26,770. Supposing, under those circumstances, you found that plague existed in a town and was not reported to you?—I should say, therefore, that the certificates must be wrong.

26,771. What would you do then?—I should put it into other agency, if I could get it.

26,772. Would it not be well to commence with a superior agency at first?—No, I would not do that. It would cast a slur on the native practitioner.

26,773. Would you give a Health Officer the power to inspect the corpse if he doubted the correctness of a certificate?—No.

26,774. You would not use corpse inspection in any form?—No, I would not. I would not do it as a Government measure. If he chose to do it on his own responsibility he could do it.

26,775. Do you adhere to the view in full knowledge of the fact that corpse inspection has been accepted quite peaceably in Poona?—In Poona the people were so frightened that you could do anything you liked with them.

26,776. (*The President.*) Why?—On account of the plague.

26,777. They were frightened?—Yes. If you tried to do anything like that in the Punjab—in Lahore, for instance—you would very soon get a disturbance.

26,778. (*Mr. Cumine.*) Poona is a large military cantonment, is it not?—Yes

26,779. When people have been evacuated, and they return secretly and sleep in their houses, do they not frequently catch plague?—I believe so.

26,780. Does not that look as if the infection lay in the cow-dung floor which they sleep upon?—My idea is that it is local infection. I do not know whether it is cow-dung or what it is, but it is something in the locality.

26,781. (*The President.*) You mean partly so, because you have said that it might be in the human being?—Yes, partly. Once it gets into a locality that becomes a fresh centre. I could not say about the cow-dung floor.

26,782. (*Mr. Cumine.*) My point was, whether it does not appear to be in the floor of the house?—I am not certain; we have no information on that point; we do not know anything about the natural history of the bacillus of plague.

26,783. Assuming, for a moment, that the infection does lie in the floor, and that the natives get it from going in with bare feet or from sleeping on the actual floor without bedsteads, would the sanitary improvements which you think are required to eradicate plague from India touch the floors?—Sanitary measures will prevent the floor and anything else becoming a source of infection, because the bacillus could not live in sanitary conditions.

26,784. Would these sanitary conditions interfere with the floor of the house?—Not necessarily.

26,785. (*The President.*) I thought you said they would, because of the fresh air and light?—Yes, in that way, but I thought you meant with regard to the floors being made of stone, lime, etc.

26,786. (*Mr. Cumine.*) Would you prescribe any particular kind of floors?—Nothing of the kind. All I would prescribe would be that the house should not be overcrowded, and that it should be built under ordinary sanitary conditions.

26,787. You would not prescribe certain sizes of windows?—No, certainly not.

26,788. (*The President.*) You would not say that there must be a certain sized window and a certain air space, but you would say they must not be smaller than a certain standard?—A decent size.

26,789. (*Mr. Cumine.*) Would you do that?—That is going into such minutiæ that it would worry the life out of the people. What I say is, have proper ventilation in the room, and then you can afford to do what you like if you have proper ventilation and proper light.

26,790. Who is going to see that that is carried out?—The Government of India or anyone else.

26,791. (*The President.*) You must have a new organisation in the whole of the Sanitary Department?—Yes, we want a new Sanitary Department.

26,792. The present Sanitary Department is scarcely able to undertake it?—It is impossible; we are merely advisers. I was merely adviser to the Government of India. I could issue no rules without their sanction, nor could I do anything without their orders.

26,793. Having regard to the vastness of the country and of the population, the present organisation is insufficient to maintain India in a sanitary condition?—Quite insufficient and ineffective. It is a defective organisation entirely.

26,794. I understand, from some answers you have have given, that you think that a satisfactory method of obtaining early information would be to accept the medical certificate of a man whose qualifications shall be afterwards defined, and alternately if that is not obtained, by corpse inspection?—Not corpse inspection.

26,795. You altogether disapprove of corpse inspection?—Yes.

26,796. Even though it has not caused much opposition, not only in Poona, but in other parts of India?—There are only one or two parts.

26,797. There are several parts of India in which it has been done without opposition?—Yes.

Surg.-Gen. J. Cleghorn, I.M.S.

6 May 1899.

26,798. Karachi certainly, and Belgaum, and two or three other places where they are carrying it out: the people have got accustomed to it, and now that they know what it means they do not oppose it so much. At all events, if corpse inspection could be done in a manner that would not cause serious opposition, you would not object to it?—Then I say, what is the object of corpse inspection?

26,799. Supposing you cannot get a medical certificate from a man whose qualifications you would be willing to accept?—I say that corpse inspection is useless to discover the disease, because you cannot find out the pneumonic form of the disease by corpse inspection.

26,800. But, supposing the number of pneumonic cases is small relatively to the bubonic cases, as it generally is, and the bubonic cases are discoverable, is it not something to discover part of the cases, if not all?—Of course, if you can do it.

26,801. (*Mr. Cumine.*) The President asked you to suppose that corpse inspection could be done in a manner that would not cause serious opposition, and then asked if you would approve of it. But that supposition is one that you find it impossible to make, I understand?—With regard to up-country, yes. I think it would give rise to great opposition. I have have always held that opinion. My idea is that if that measure were imposed on the people up-country, it would certainly not be worth the opposition it would give rise to.

26,802. You said that where the Collector was a good officer he would manage to get all the people out of an infected town very readily?—I think so. I do not mean a good officer in the sense of being a good Civil officer; I mean a man with a certain amount of individuality and tact, and a man who knew the natives. I think he could do anything he liked with them if he has their confidence.

26,803. I was going to ask you whether, though he would gladly do it one year, and ask all his people to go out one year, and they would go out one year, would he be ready to keep on asking them to go out in two or three successive years, and do you think they would continue to be willing to go out two or three years in succession?—Certainly, if the arrangements were good for housing them; but with such repetitions, the question would naturally arise as to providing new and permanent accommodation for the people.

26,804. (*Prof. Wright.*) How would you propose to find out the cause of death by medical certificate in the case of people who are not seen by a medical man?—That is difficult.

26,805. Would you have corpse inspection then?—No.

26,806. Would you let these people be buried without diagnosis?—There would always be a way of getting over it. The Medical Officer of the district in which the death had occurred would know.

26,807. You would take his certificate?—Yes; he would manage to find out by asking the people: he could see the body and see if there were signs of plague.

26,808. Would you take a relative's opinion?—No.

26,809. Would you not sooner have corpse inspection?—No, it is so distasteful to the people.

26,810. Supposing it can be done, would you not think it would then be advisable to try it in cases where you get no medical certificates?—I am not in favour of it; it is so utterly repugnant to the people when they are in a normal condition. They would not allow me to touch a corpse in the ordinary course of practice. I could not go near the body, and especially near the body of a woman—they would not allow it. I have asked all classes of Muhammadans and Hindus about it, and they all say it is utterly repugnant to their system of religion.

26,811. (*The President.*) But in some parts of India the Muhammadans have submitted to corpse inspection?—I daresay they have, either from being cowed, or seeing the hopelessness of opposition.

(Witness withdrew.)

Dr. W. J. Simpson, F.R.C.S.

6 May 1899.

Dr. W. J. Simpson, F.R.C.S., called and examined.

26,812. (*The President.*) You are a Doctor of Medicine?—Yes.

26,813. And you have lately been Health Officer in Calcutta?—Yes.

26,814. Within what time were you Health Officer in Calcutta?—From May 1896 to September 1897.

26,815. During that period did you see in Calcutta any cases of plague?—Yes.

26,816. When?—About the beginning of October 1896.

26,817. Would you give us a description of the cases you considered to be cases of plague?—The cases of fever and glandular enlargement in Calcutta, and which were suspected to be cases of plague, that came under my observation were as follows:

(1.) On 8th October, one case at Howrah, that of a Goanese youth, aged 17, named Cotta. He had arrived from Bombay 12 days previously. I was asked to see him by Surgeon Lieut.-Colonel Tomes. He had enlarged glands on each groin, which were tender. There was no sign of syphilitic or venereal affection. There was no history of injury. The full history of the case is given in my Annual Report for 1896, p. 18, from which I extract the following:—

"In October a case of glandular sickness with fever occurred in Howrah, in a patient who had arrived from Bombay. Surgeon Lieut.-Colonel Tomes asked me to see the case, which I did, with Dr. James, on October 8th, 1896. The patient, without any history or sign of syphilis or venereal affection, was suffering from tender buboes on each groin, and had a temperature of 102°; though perfectly sensible and intelligent, he seemed to require to be aroused before he answered any question. His eyes were somewhat suffused, and tongue furred in the centre, and red at the tip and edges, he had on his legs, arms, and body an urticarial-looking eruption, and distinct from this, on his back and shoulders, was, here and there, a reddish rash varying in size from less than a split pea to that of a bean. He had started from Bombay on the 23rd September, arriving in Howrah on the 26th, and was attacked with fever on the 28th. With careful antiseptic precautions the patient's finger was pricked, and cover-glass preparations were made. The needle of a syringe was inserted under his skin, and a small quantity of blood drawn off and inoculated into two culture tubes of nutrient agar and bouillon. With similar precautions blood and serum were taken from the glands and groin, and culture tubes inoculated. The microscopical specimens were examined the same night and found to contain diplo-bacteria.

"The next morning the patient was seen by Dr. Cobb, Dr. Tomes, and myself, and after careful examination the following notes were taken:—

"*History of Patient.*—J. C., aged 17 years, who had been living with his father, a telegraph master, residing at Bellasis Road, Byculla, Bombay, came with his sister to Howrah on a visit, and took up his residence in Ghose's Lane, Howrah.

"In Bombay, he attended the Byculla School. He left Bombay with his sister on the 23rd of September 1896, and arrived in Howrah on the 26th September. About 15 days before leaving Bombay, he noticed the gland of the left groin to be enlarged and painful, then the gland in the right groin began to enlarge, but he felt quite well until he reached Nagpur, on the 24th September, when he began to experience symptoms of malaise, loss of appetite, and the glands in the groin grew larger, and four small rounded pimples appeared on the penis. These pimples lasted for four days. He remained much about the same until his arrival in Howrah, when, on the 28th September, he was attacked with fever, which was of a remittent character, being worse at night than in the morning. He perspired profusely and suffered from severe itching, due to urticaria. The pain in the groin was of a dragging character, but did not interfere with his walking about until the last few days, when, on account of the discomfort in the groin, and the heaviness in his head, he was obliged to take to his bed. The sister of the patient stated that she was well acquainted with the plague, as she had seen several cases while in Bombay.

"On examination of the patient on October 9th, his countenance appeared heavy, and there were dark hollows around the eyes. His tongue was covered with a whitish fur in the centre, the edges being red. His conjunctivæ were slightly congested. He seemed dull and apathetic in answering questions. His head was hot to the touch. Patches of urticaria, varying in size from a pea to a bean, were scattered over the back, forearm, and legs. There were also some small reddish patches which disappeared on pressure, and which varied in size from a pea to that of a four anna piece or larger, on the skin of back and shoulders. These were not observed on any other part of the body. In the right groin was an enlarged gland, the size of a hen's egg. It was situated above Poupart's ligament. It was hard and slightly tender. In the left groin, there were two enlarged glands, one similar to that on the right side, but smaller; another, the size of a small marble, was situated below Poupart's ligament, and was more tender than the others. The penis was carefully examined and found to be free from sores. On inquiry, the patient denied that he had ever had syphilis. The spleen, liver, heart, and lungs were examined and found to be healthy. There was no sore throat. There were no other enlarged glands in the body. The patient stated that the bowels were regular and urine natural. Pulse 110. Temperature 99·6 in mouth. Blood was taken from the finger and examined at the laboratory.

"After a prolonged consultation, Dr. Tomes, Dr. Cobb, and myself, came to the conclusion it was a case of *pestis ambulans*.

"The Medical Board,* investigating the case later on, came to the conclusion that there was no evidence to consider this a case of true bubonic plague."

26,818. Of whom did the Medical Board consist?—Mr. H. H. Risley, Secretary to the Government of Bengal, in the Municipal and Medical Department; Mr. J. G. H. Glass, Secretary to the Government Public Works Department; Dr. G. C. Ross, Inspector-General of Civil Hospitals; Mr. P. Playfair, Sheriff of Calcutta; Dr. D. D. Cunningham, Professor of Physiology, Medical College; Dr. H. J. Dyson, Sanitary Commissioner, Bengal.

26,819. Your microscopical examination was restricted to a determination of the morphological characteristics?—Yes, at that time.

26,820. And at any other time?—Later cultures were made from some of the blood which was taken from the groin. In slide specimens prepared from the blood of Cotta, some of the Shropshire cases, Tincauri Pal, Grace Hodges, Heman Shah, Surendra Nandi, Giga, Bepin, Golab, and the rats suffering from glandular sickness, there were bacteria of a diplo-bacterial character, and morphologically similar to the specimens of plague in man and rats from Bombay.

26,821. I understand you did more than that?—From Cotta a comparatively pure specimen was obtained, which afterwards became contaminated. Sub-cultures were made from Cotta, which were taken from the blood.

26,822. While he was alive?—Yes.

26,823. At what period in the illness?—It must have been about three weeks after the glands began to enlarge.

26,824. Late in the disease therefore?—Yes.

26,825. Was he convalescent?—He was not convalescent.

26,826. Was he pyrexic?—Yes, he had a temperature of 102° at that time.

26,827. Your cultures became contaminated, I understand?—Yes.

26,828. Could you draw any conclusions from these contaminated cultures?—No.

26,829. Did you have other cultures from this man which were not contaminated?—The first cultures appeared to be contaminated, and then later, the microbe, or what appeared to be the microbe, was isolated, but after passing this through several generations this microbe, which seemed to be pure at first, ultimately became contaminated.

26,830. Did you do that in a culture medium?—Yes.

26,831. Will you describe the character of the culture, its appearances, and in what you cultivated the microbe?—I cultivated it first of all in bouillon and agar. It was a bouillon culture which ultimately became contaminated.

* *See* App. No. XXI. in Vol. I. of these Proceedings.

I had, as standard specimens, cultures from Bombay brought to me by Dr. Dutt. I sent my assistant, Dr. Dutt, to Bombay, at the time of the outbreak of the plague there. He worked with M. Haffkine for a short time, and M. Haffkine was kind enough to give him cultures obtained and prepared from plague patients. Dr. Dutt also brought cultures from plague patients which he had himself prepared in Bombay. Then he brought me also Dr. Surveyor's cultures from plague affected rats in Bombay. Cotta's cultures appeared in many respects very much like the cultures that Dr. Surveyor had made from the rats.

26,832. What do you regard as the distinguishing character of the cultures in the case of the true plague microbe?—At that time we did not know so much as we do now. Haffkine's test method was not in existence, and we had simply to go by the morphological appearance under the microscope, and the bluish whitish appearance of the growth on the agar. We had nothing further to go by at the time.

26,833. Did you make any experiments on animals with regard to the toxicity of any of the substances or products obtained from Cotta?—Yes. I am confining my observations to the case of Cotta. I inoculated a guinea-pig with the cultures.

26,834. That is when you got it in a pure form differentiated from the other organisms?—Yes, I inoculated it into a guinea-pig, which was about 500 grammes in weight.

26,835. How much did you inoculate?—Into the guinea-pig 1 c.c. was injected into the peritoneum. 1 c.c. was also injected into the peritoneum of a mouse. The guinea-pig died in four days time, and the mouse died in 30 hours. Similar doses were injected subcutaneously into a guinea-pig and a rat of the same weight, and the only result was loss of weight.

26,836. In all these experiments?—In Cotta's case.

26,837. Do I understand that you injected the products from Cotta into several guinea-pigs and several rats?—Yes.

26,838. And in each case they recovered?—Yes, when injected subcutaneously.

26,839. Did you make any intra-peritoneal injections also?—None, other than those mentioned.

26,840. Only subcutaneously?—Yes.

26,841. The experiments appear to show that it was not an active virus?—It showed it was not an active virus.

26,842. And 1 c.c. is a large quantity, is it not?—Yes, it is an enormous quantity.

26,843. Will you proceed to the next case?—The next case brought to my attention was on the 10th October. Surgeon-Lieutenant Cobb showed me a letter from Surgeon-Major Skinner, which was as follows:—"The case of *pestis ambulans* published in "to-day's paper has aroused our curiosity to know "more about it. Among the soldiers, for certainly "a year past, we have had cases of fever, followed, or "preceded, or accompanied by enlargement of glands "in the groin. There has been no suspicion of "venereal origin. A lad will sometimes come into "hospital with malarial fever, which will run its "course, leaving him cachectic; while being treated "for the cachexia he will grow a bubo. Sometimes a "a man comes in with a non-venereal and non-infected "(*i.e.*, by sepsis) bubo with fever. These buboes will "suppurate in a sluggish manner, and take a long "time to get well. We call them malarial buboes. "When I had dysentery in July last I got small "buboes on both groins. The glands here are still "perceptible, as also in both axillæ. How is one to "diagnose between these cases and a case such as "that of Cotta, reported in to-day's paper? I may "add that, before I came to Calcutta, the above cases "were looked upon as venereal, though without vene-"real origin. It was only when I drew particular "attention to them that they were recognised as non-"venereal." A few days after this I visited the Military Hospital with Dr. Cobb and saw 10 cases belonging to the Shropshire Regiment. The Shropshire Regiment arrived in Calcutta in January 1895 from Hong Kong.

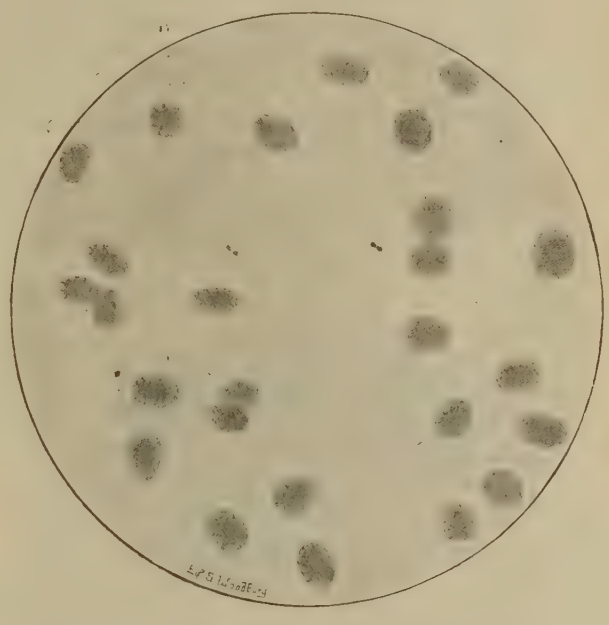
26,844. You say the cases were in October 1896?—Yes.

26,845. The Shropshire Regiment arrived in Calcutta in 1895?—Yes, in January 1895, Dr. Cobb had visited these cases previously and taken from a number of cases specimens of blood from the finger. He came to my laboratory. The specimens were stained immediately, and in a number of them these were diplobacteria of a kind. For example, I have here a drawing (No. 1.) of one which was taken from the

Dr. W. J. Simpson, F.R.C.S.

6 May 1899.

I.



microscopical specimen; it was drawn by Professor Cunningham's draughtsman. I have some others also (*handed to the President*).

26,846. Was anything further done in the microscopical examination besides determining the morphological characteristics?—That is the result of Dr. Cobb taking these specimens. Then I visited the hospital with Dr. Cobb.

26,847. (*Prof. Wright.*) These were specimens taken by Dr. Cobb?—Yes.

26,848. Were they stained by you or stained by him?—I could not exactly state whether they were stained by him or by myself.

26,849. Do you remember how they were stained? That is the point?—They were stained in my laboratory; and I was with him.

26,850. What dye were they stained with?—I think they were stained with methylene blue. Some were stained with eosin.

26,851. Dr. Cobb stained several of them, and you stained the others?—Yes.

26,852. Were the morphological characteristics the same in both?—Yes, they were the same.

26,853. Was there any other examination?—Yes. A few days afterwards I went with Dr. Cobb, to the Military Hospital, and, with the permission of Major Skinner, took some blood from two of the patients there. The method adopted was as follows:—I used a hypodermic syringe. I took out the ram of the hypodermic syringe, and attached some gutta-percha tubing to the barrel of the syringe. I thoroughly boiled this apparatus, and then inserted it into the basilic vein, and drew blood into some tubes containing bouillon and into others containing nutrient agar. I took about 12 tubes from each of the two cases, and in a few days—about three days—there were growths in some of them; and in others there were no growths. I isolated these growths, one from the man Rabbid and another from Finney. Those were the names of the soldiers. The one from Rabbid grew very slowly, in single colonies, in different parts of the agar when I transferred it. The growth was exceedingly slow, but morphologically it showed diplobacteria under the microscope. Finney's, at times, morphologically showed diplo-bacteria, which at other times developed into chains, but at other times grew

Dr. W. J. Simpson, F.R.C.S.

6 May 1899.

very irregularly, and I cannot say whether they were involution forms or contaminations.

26,854. You got these cultures from the second man, Finney?—Yes.

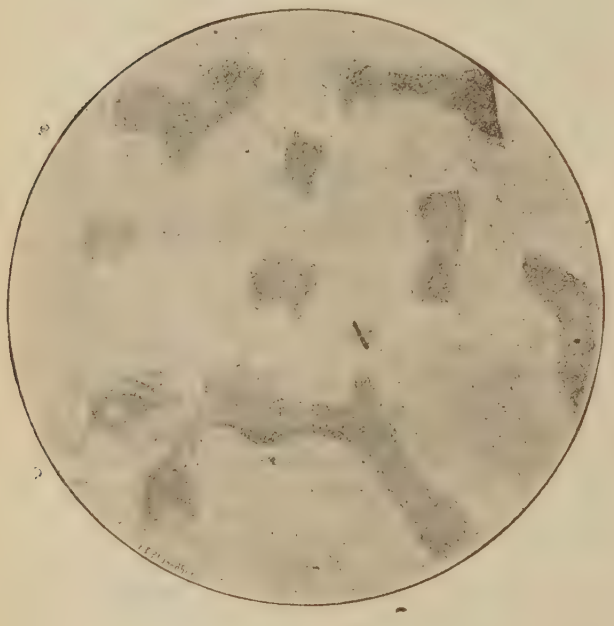
26,855. Did you only draw off blood on one occasion?—Yes.

26,856. (*The President.*) What do you mean by saying that at times such and such a thing occurred, and at other times something else? Do you mean in different or in the same cultures?—Yes, they did not seem to act always in the same way; so much so that I thought there must be contaminations. Sometimes the irregular growths reverted to this diplo-bacterial character again.

26,857. Do you mean in the same specimen?—Yes, after passing through several generations.

26,858. (*Prof. Wright*) Have you any drawings to illustrate this?—That (No. 2) is only the slide specimen

II.



I have. The reason I have not a drawing of Finney's case was that I sent the specimen then, along with others, to Dr. Havelock Charles, who was going home through Japan, and who was kind enough to take them to show to Kitasato, to get his opinion upon them.

26,859. Dr. Charles told us in Calcutta that he had submitted the specimen to Kitasato, and Kitasato said they were diplo-bacilli?—I did not know that Dr. Charles had given evidence on this point. I injected the cultures from Finney and Rabbid subcutaneously into guinea-pigs and rats, but they produced no effect whatever.

26,860. (*The President.*) And in large quantities?—Sometimes as much as 2 c.c.

26,861. Do you recollect in what period of the disease the blood of these specimens had been drawn from these two soldiers?—I do not know how long they had been in hospital. I suppose they might have been in hospital three weeks.

26,862. Do you know if they were suffering from any acute symptoms at the time?—They were in bed.

26,863. Do you know if they had a temperature above the normal?—No, I do not.

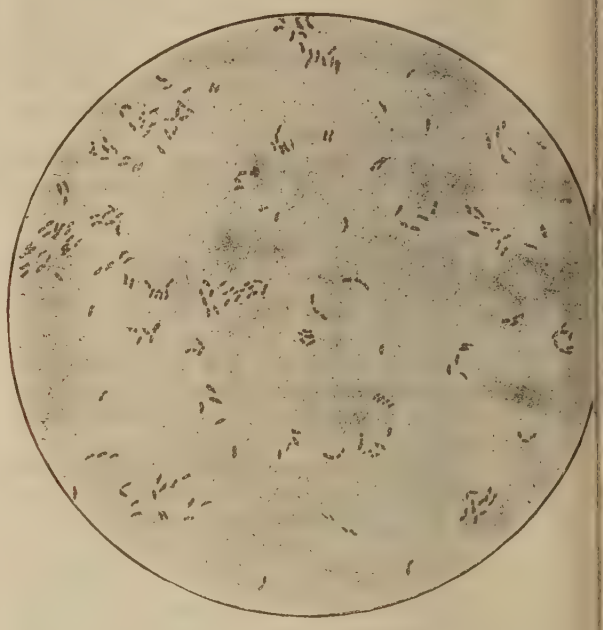
26,864. You have noted the glands which were affected, have you not?—They were in the groin.

26,865. In both groins in each case?—I am not certain.

26,866. But at any rate in the groin?—Yes.

26,867. Is there anything more you wish to say about these cases?—This (No. 3) is a drawing of diplo-

III.



bacteria from the man Rabbid (*handed to President*). It was drawn by the same man who drew the others.

26,868. Would you go on to the next case?—In the second week of October three cases of fever with glandular enlargement were reported to me among children. The names of the children were Tincauri Pal, aged 14, who worked at a jeweller's in Kansaripara Bhawanipur, and who had a considerable dealing with the Marwaris; Grace Hodges, aged seven, whose father was a Custom-house officer, and who lived in Chattawal Gali, Bowbazar, the case was reported by the authorities at the Medical College; and Heman Shah, aged 12, by trade a hawker, living in Jaunbazar Busti, Fenwick Ward. The history of these cases is as follows:—Tincauri Pal, aged 14, lived at Elgin Road, Calcutta. He was apprenticed to a jeweller living at Kansaripara, Bhawanipur. He began to be ill on 5th October with fever. For four or five days previous to this he had had ulcers on his tongue. I described the case at the time with great minuteness, because there was no certainty as to what they were, and I thought it desirable to record exactly what was seen.

26,869. There was no suspicion of these ulcers being syphilitic, was there?—Oh, no. On the 6th October he attended the Bhawanipur Hospital. He had no pain then. On the same day he noticed a swelling in the left groin, and it was painful and tender on pressure. On the 8th, the temperature was 103°, on the 9th, 104, on the 10th, 104°. When the fever rose he had headache in the temples. On the night of October 9th he was delirious.

"*Present Condition.*—On 10th October, afternoon, temperature 104°, pulse 98, tongue furred in centre, a portion of the epithelial lining of the front of palate denuded in patches. A purple coloured rash, varying in size from that of a split pea to that of an eight anna piece, thickly studded on back. Patient's friends state that urine first passed was yellow, and that last passed, colourless. Bowels said to be natural. A bulla on left leg about the size of a two-anna piece. On left groin were three glandular enlargements, one the size of an egg, the second slightly smaller, and just below Poupart's ligament, and the third below these, and the size of a marble; on the right side one of the glands below Poupart's ligament is slightly enlarged. Face somewhat pale, eyes slightly congested, perspires profusely." Blood was taken from the finger, and on examination was found to contain diplo-bacteria. I say 'found to contain diplo-bacteria.' I might have to search half-a-dozen slides before I found them. Diplo-bacteria were not there in numbers. My method of preparing the slides was as follows:—I always had slides prepared in the laboratory, and then put into alcohol. In this case

I washed the finger thoroughly first with soap and water.

26,870. And nothing more?—No. After that I swabbed it with a solution of carbolic acid, and then with a little alcohol, and then pricked the finger, and with a sterilised needle spread the blood over the whole slide, dried the specimens thus made, and then put them into a box and took them to the laboratory at once and examined them.

26,871. Then there was the chance of contamination, was there not? The actual blood was not in any way covered except by being put into the box?—Not in this case. I stained it in the manner already described, and found a similar organism to that I had previously found in the other.

26,872. Do you know what the after-history of this case was?—He went to the hospital and got rapidly well. The Medical Board saw him after a few days, and came to the conclusion that it was not a suspicious case.

26,873. Did the enlarged glands suppurate, or did the enlargements simply become absorbed?—They became absorbed.

26,874. Did you do anything else in the examination of the blood?—No, not in this or the next three cases; they were merely slide specimens.

26,875. Will you give us the next case?—The next case was Grace Hodges. The history was as follows:—On 8th of October she complained of feeling ill, with pains all over the body. On the 9th October she complained of pains in the groins and fever. On examination her mother found the glands in the groin enlarged, and also those of the neck. On the same day the mother took her to Chandni Hospital, where the doctor found the glands in the axilla enlarged, and the temperature of the child was 99°. The Chandni Hospital doctor told the mother it was a suspicious case. Afterwards the doctor wrote a letter stating that he thought this was a syphilitic case. On the evening of the 9th the temperature rose to 102°, but the next day (10th October) after a dose of castor oil, the child seemed better. On the morning of the 11th October she was taken to the Medical College Hospital, where she was also told that the case was a suspicious one of plague, and the Medical College authorities officially notified the case as one of suspicion to the Health Officer. On this notification Dr. Cobb visited the house, in company with Dr. Vaughan, and found the patient in a small house in a crowded locality. The child walked to an upper room, where we examined her and found the following:—

"She looked pale and weakly. Her tongue was furred in the centre and red at the edges. The breath was foul, the bowels said to be regular, eyes clear. There was no rash on the skin, there were no sores on the feet, or signs of irritation about the genitals. There were three small boils on the back and one on the side of the head behind the ear; the skin was dry, and the mother stated she had not noticed any excessive perspiration. There were three enlarged glands under the anterior folds of the right axilla, each about the size of a small marble; there were two similar ones under the anterior folds of the left axilla, and another at the apex of the left axilla. There were three enlarged glands in the left groin above Poupart's ligament, and there was a vertical chain of small enlarged femoral glands on the right side. The enlargements of the glands were more marked on the left side. The cervical glands on both sides of the neck were felt to be enlarged. Blood taken from the finger showed diplobacteria."

26,876. Why was it supposed to be a case of syphilis? What information did you receive?—I think it is stated in the letter of Dr. Panioty that he had attended the sister who had had syphilis, and the child herself had teeth which indicated hereditary syphilis.

26,877. Did you see the father or mother?—Yes.

26,878. Did you make any inquiry as to the possibility of syphilis?—No, we did not. We examined the child thoroughly.

26,879. I mean did you examine the parents?—No.

26,880. Will you give us the next case?—The fourth case was Heman Shah, a boy, aged 12 years, living at 134, Jaunbazar Street, Fenwick Bazar, who came from Monghyr four months ago. On the 10th of October he was attacked with fever, and for two days he passed loose stools, and was delirious at night. On the 12th he was seen by us; his temperature was 103. He was prostrated and complained of severe headache. He had a peculiar, apathetic, and dazed appearance, his eyes were suffused, his tongue was much coated in the centre and red at the edges, pulse was small and very soft. There were no eruptions on the skin. The inguinal glands were slightly enlarged, but not particularly tender to pressure. Blood was taken from the finger, and found to contain diplo-bacteria. On the morning of October 15th his fever was less, and he seemed to be more sensible. He was removed to hospital and, on admission, his temperature was 99. His skin was dry. There was no rash, no head symptoms, tongue moist and reddish. No pain or tenderness in the abdomen. Bowels were constipated. Slight cough, moist râles here and there in both lungs, specially at left base. Heart normal; pulse moderately full and regular; no splenic or hepatic enlargement. Lymphatic glands of neck, right axilla, and both groins were enlarged. On October 14th blood showed diplobacteria.

26,881. Will you describe the enlargements of the glands in this case?—Some were very similar to the others. They were not very large. They were about the size of a small marble.

26,882. Were the margins of the enlargements quite definite?—No; they were somewhat suffused.

26,883. Was there any swelling surrounding the glands?—There was a slight swelling surrounding.

26,884. Where is Monghyr, where the patient came from?—It is in North-Eastern Bengal.

26,885. I ask you because I want to know whether there is any possibility of there having been plague cases in that district?—No, I do not think so. There was not much communication.

26,886. You have no knowledge of any source of infection in Monghyr?—None whatever.

26,887. Will you proceed with the fifth case?—The fifth case was S. M. N., aged 9 years, living in Old Chinsura, who was examined on the 19th October. Dr. Dutt, of Chinsura, who attended the patient, reported the case to me by mistake. It ought to have been reported to the Medical Board. The Medical Board asked that all cases of a suspicious character should be reported to them wherever they might occur, but Dr. Dutt made a mistake, thinking the report ought to be made to me. On receiving the report Dr. Cobb and I met Dr. Dutt and examined the case.

26,888. Is Chinsura a part of Calcutta?—No it is a little north of Calcutta, on the other side of the river. It is about 20 miles north of Calcutta. This is the history which Dr Dutt gave me. The boy took ill on the 5th October with strong fever and severe pains in the forehead and temples; his temperature in the axilla varying from 102 and upwards, rising on the 8th and 9th to 106. After this it fluctuated between 102 and 104. On the 10th October he became delirious; no rash was observed on the body, nor had he any attack of shivering. On the 11th October the glands in his neck, groin, and axilla, were noticed to be enlarged and tender, and they were painful. On the 13th October, Dr. Dutt found the boy's temperature to be 102·6. He noticed a dull and stupid expression on his face; the tongue covered with a whitish fur in the middle, with red tip and edges. There was no sore throat. The glands of the neck were swollen on the right side specially, particularly the chain of glands behind the sterno-mastoid muscle. At night the fever rose to 104·6, and then to 105. He was delirious, with a pulse of 128—small, weak, but regular. The heart sounds were weak, the first sound being almost inaudible. There were a few râles on the bronchi, and the breath sounds at the bases of the lung were weak. There was congestion at bases. There was no enlargement of the spleen. The liver dulness was normal. The urine was high coloured, sp. gr. 1,009, and it contained a small quantity of albumen.

"*14th October.*—Temperature 102·6 in the morning, evening temperature 103·5. The boy complained of pain in the left axilla, but no swelling was perceptible; he was much worse in every way. Pulse 130 to 135,

Dr. W. J. Simpson, F.R.C.S.

6 May 1899.

and respiration 55 to 60. Dr. Dutt, at this period, feared a fatal issue.

"*15th October.*—The glands in the right axilla became painful on this day. Dr. Vaughan saw the patient, and took some blood from the finger. Morning temperature was 102·6, the evening temperature 104.

"From the 15th to the 19th October there has been a gradual improvement, the fever and the glandular swelling gradually subsiding, but the patient remains in a very weak state. Present condition, as recorded by Dr. Cobb, who made the medical examination: The child was lying on his back in a weak and exhausted condition, with a peculiar dull and apathetic look on his face. The eyes were sunken with dark hollows round them. The conjunctivæ were not congested. Tongue covered with a white fur in the centre with red tip and edges. Pulse was 120. Temperature 100·6 in the mouth. Respiration, 50 per minute.

"*Lungs on Percussion.*—The sounds were normal except at the right base, where there was some loss of resonance.

"*On Auscultation*, bronchial and crepitant râles were heard at both bases, and there was bronchial breathing at the right. Liver and spleen were normal in size.

"*The abdomen* was somewhat distended; there was no sore on the penis or prepuce.

"*Right Groin.*—One inguinal gland was found to be enlarged to the size of a betel nut; it was surrounded by three smaller glands, one being femoral.

"*Left Groin.*—There were four enlarged inguinal, and one femoral gland in this situation.

"The deep *lumbar* glands were felt to be enlarged.

"*Neck.*—The chain of lymphatic glands at the back of the stern-mastoid muscle on the right side were felt to be enlarged, as also were some of the glands in the front of that muscle.

"In the *left axilla*, a gland of the size of a large bean was felt in front of the posterior fold.

"In the *right axilla*, a small gland was felt in the inner side behind the anterior fold."

Blood was taken from the median-basilic vein, and found to contain diplo-bacteria.

26,889. Was that on the first occasion or on the second occasion?—On the second occasion. Blood was also taken by Dr. Vaughan.

26,890. (*Prof. Wright.*) Was that only a cover-glass specimen?—Yes; I took blood from the median-basilic vein; but, unfortunately, I used a syringe, which had been sterilised, and had been used for the anti-cholera inoculine. After filling the syringe and when putting some of the blood into the culture media, it was distinctly noticed that the syringe was defective, and that air was being injected into the tubes as well as blood. I had half-a-dozen cultures, and one of those I sent to Dr. Cunningham at once; the other five were retained. In a few days I discovered the whole of these were contaminated. They certainly had aërial organisms in them. I informed Dr. Cunningham of the matter, and it is one of those cases which he mentions in his report where there was contamination. These were the circumstances.

26,891. (*The President.*) That examination was not satisfactory?—It was not satisfactory.

26,892. Will you proceed to the next case?—On the 20th October, the death of a woman, named Golab, was reported to me by one of my inspectors and by the police. I went to inspect the body before it was burnt, and was accompanied by Captain Vaughan and two of my medical assistants. On inquiry, we found that she had suffered from high fever, and from swelling of the glands on one side of the neck. These were not parotid glands. On inspection, we found no swelling in the groins, but a swelling of the glands on one side of the neck. Blood was drawn by a sterilised hypodermic syringe from the heart, which was found to contain large numbers of diplo-bacteria, but as all the cultures were much contaminated, no decided opinion was formed at the time. After seeing similar cases in Poona, I am satisfied that this was a case of plague.

26,893. What was the cause of the contamination?—The body had been lying there for a few hours before we reached the place.

26,894. So far as the bacteriological examination was concerned the result was nil?—Yes, it was nil.

26,895. Then will you give us the seventh case?—On the 1st November, a child named Giga, aged about 4 years, the son of a Marwari, living at 13, Armenian Street, was reported to me by Major Charles, Professor of Anatomy at the Medical College, and Second Surgeon to the Hospital, as being a suspicious case of plague. The following history was given me by Dr. Charles:—"Ill about 10 days; fever and slight "bronchial catarrh; glands of left axilla enlarged to "the size of small marbles; those of right axilla "enlarged, but less so. Glands of right groin palpable; "one gland in left groin inflamed, and will suppurate, "sub-occipital glands can be felt, but do not count, as "child has had eczema of the auricles." I thought I had his letter, but this is a quotation from the letter.

The gland was opened and pus and blood specimens taken, and diplo-bacteria were found in the groin. The microbe could not, however, be isolated, owing to contamination; the reason being that the abscess was opened in the room before any precaution had been taken. The people in the house were Marwaris, who received goods, clothing, and yarns from Bombay. On inspection of the warehouse below, in which the child Giga was accustomed to play, a rat was found, sitting on the step, looking very ill. It did not attempt to escape, and seemed to be in a dazed condition. The rat was taken to the laboratory, killed there, and immediately examined. Its glands in the left groin were found to be enlarged, congested, and agglutinated together. The internal organs were generally congested; diplo-bacteria were found in the blood and internal organs, and cultures from these gave growths resembling specimens of plague bacilli in rats received from Bombay. Healthy rats were examined, but no bacilli were found in their organs. I examined at that time seven healthy rats from other parts of the town. The following are notes made at the time on the condition of the rat suffering from glandular sickness in November 1896 in Calcutta:—

"*1st November* 1896.—Rat from 13, Armenian Street, found ill, furred coat, eyes dull and watery, seemed to be unable to move freely, did not run away when approached by people. Killed at 1 p.m. Blood, when examined, found to contain diplo-bacteria and large coccoid bacteria. On deflecting the skin, the glands, in both inguinal and axillary regions, much enlarged and inflamed. Spleen enlarged, liver enlarged and soft, heart dark in colour, kidneys enlarged and congested, blood very watery, lungs light grey with darker patches. Bouillon and agar inoculated with blood from heart, spleen and liver. In two days bouillon and agar showed diplo-bacteria similar to those in the specimens in the rat.

"*3rd and 4th November.*—Seven healthy rats examined, and microscopic specimens made from heart, liver, and spleen. No microbes observed in the specimens. Cultures from five show no growths, cultures from two show micrococci and bacillus subtilis." It was found that the enlarged glands and the organs were filled with diplo-bacteria.

26,896. Could you give us any particulars of the appearance of the growths in the agar and bouillon cultures?—The appearance of the growths was in bouillon slightly granular, and on agar bluish white colonies. At first they grew much more rapidly, apparently, than those which I have been speaking of, and much more luxuriantly. Under the microscope a number of them had a coccoid form, but were much smaller than in the specimens I had received at Bombay—M. Haffkine's specimens. They were smaller, but that was the only difference I could see.

26,897. Did you take any steps to ascertain whether any of these cocci were pathogenic?—No, unfortunately, I did not. I did cut off part of the organs of this rat and let other rats eat the pieces, but no result followed.

26,898. Will you give us the eighth case?—A week later there was an outbreak of glandular sickness, with great mortality, among rats in two houses in the Marwari quarter. It was reported to me by the inspector of the special cleansing gang working in Jorabagan that within a few days there had been an unusual mortality among rats in two grain shops in Burtolla Street.

26,899. Is this quarter near Armenian Street?—Yes, just a little north of Armenian Street.

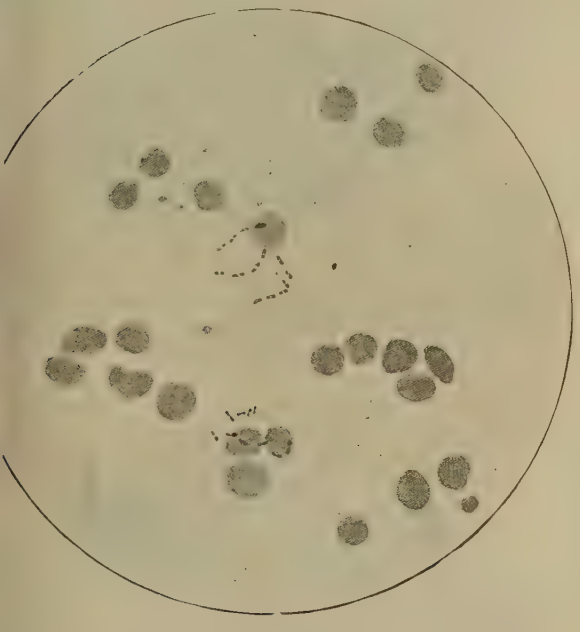
26,900. Therefore, these houses were near 13, Armenian Street?—They were not near; they were separated by at least three streets.

26,901. Do you know if these people had any intercommunication with the people in Armenian Street?—I do not think so.

26,902. Did you inquire into that?—I did not.

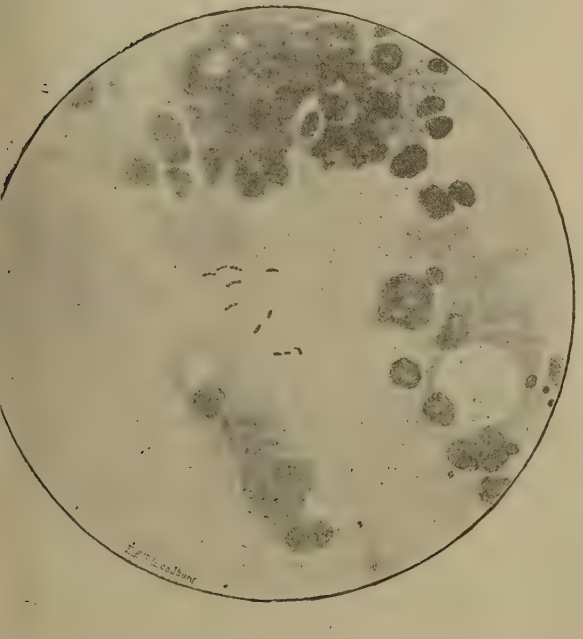
26,903. Will you proceed?—Dr. Cobb and I visited the two grain depôts, 81 and 14, Burtolla Street, and saw nine sick rats and eight dead in 81, Burtolla Street, and one sick rat in 14, Burtolla Street. 14, Burtolla Street is nearly opposite No. 81. Some sick rats were taken to the laboratory and examined, with the same result as that obtained from the rat in 13, Armenian Street. This (No. 4) is the drawing of the

IV.



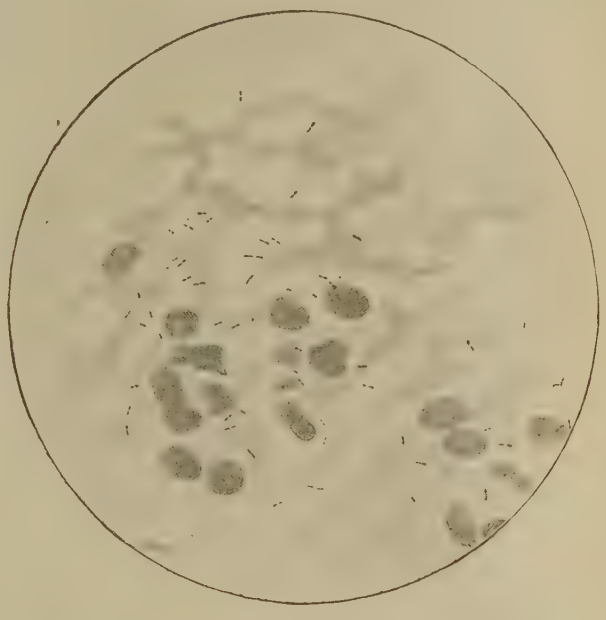
plo-bacteria in the spleen of one of them; this (No. 5)

V.



of the diplo-bacteria in the liver of another; and here (No. 6) is the drawing of the plague bacillus in the

VI.



gland of a rat in Bombay which was sent to me. Steps were taken to have No. 81, Burtolla Street closed. Meanwhile, the number of deaths among the rats was recorded, the mortality in 81, Burtolla Street reaching in one day to 100. The floors were dug up; the place flooded with disinfectants, and any rats found killed; after which, no further cases occurred. This history was repeated in No. 14, Burtolla Street, somewhat later, with a similar result. A few sick rats were found in adjoining houses. These houses were also thoroughly cleansed and disinfected, and the rats destroyed. After this, it became evident that the epidemic among rats was checked, as no other sick rats could be found. Examination of healthy rats showed them to be free of diplo-bacteria.

26,904. What disinfectants did you use?—Crude carbolic acid. I will give you the extract from my notes on the *post-mortem* :—

"*9th November.*—Three rats, No. 1, No. 2, No. 3, brought from 81, Burtolla Street. One died on the way to the laboratory, and was, therefore, not examined; another died in the laboratory, and a *post-mortem* was made at once. The axillary glands on the right side were enlarged, the liver was enlarged, and there was a greyish deposit on the surface. Specimen of spleen pulp showed diplo-bacteria in pure culture. The liver pulp showed diplo-bacteria, and the blood from heart showed diplo-bacteria. Cultures in bouillon next day showed diplo-bacteria in chains, and large cocciform bacteria single and in chains.

"*11th November.*—Rat No. 4, sent by Dr. Banks from Burtolla Street. The rat died a short time after arrival. *Post-mortem* held at once. The glands of both groins found to be enlarged. Liver congested with greyish white deposit on surface; spleen large and congested; the lungs and the auricles of heart congested; spleen and liver pulp showed diplo-bacteria varying in shape from the coccoid to the diplo-bacterial form.

"*16th November.*—Rat No. 5. Killed one of two rats brought yesterday from 81, Burtolla Street, the other having died during the night. *Post-mortem* showed no enlargement of glands. Intestines not inflamed. Liver not congested, but has a few whitish granular spots on the surface. Spleen congested, dark coloured, and enlarged. Heart normal. Specimen of heart blood, liver, spleen, show numerous diplo-bacteria, many of which were in chains.

"*19th November.*—Rat 6, sent by Mr. Scott, the inspector, from 81, Burtolla Street. Died at 2.40 p.m.

Dr. W. J. Simpson, F.R.C.S.

6 May 1899.

Post-mortem at once Has nearly the whole of its hair denuded. Has a large swelling on the neck about the size of a marble, another swelling of the same size under the left axilla; another swelling oblong in shape about three-quarters of an inch in length and half an inch in breadth on left groin. On deflecting the skin on abdomen and chest, the inguinal and axillary glands on right side slightly enlarged, those on left much swollen. The liver is enormously enlarged, occupying nearly half the abdominal cavity; the surface is spotted with white caseous matter; the pus from the glands teems with diplo-bacteria.

"20*th November*.—Cultures from glands show diplo-bacteria mixed with straight bacilli; cultures from heart blood show diplo-bacteria and coccoid bodies single and in chains, and a few long bacilli."

26,905. Were they inoculated into other animals?—No; I, unfortunately, missed doing so. I was extremely busy at the time, and was unable to carry on the investigation as I should have liked.

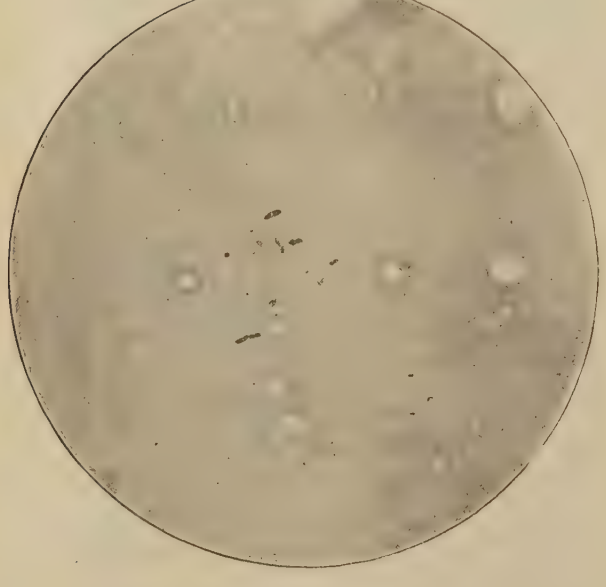
26,906. I understand that there were no cases among human beings associated with this rat-mortality?—No. One of the circumstances against the likelihood of cases occurring amongst the inhabitants was that in No. 14, Burtolla Street there were no inhabitants. We had turned them out previously. It was only a grain depôt, and in No. 81, Burtolla Street we turned the people out immediately from the lower floor, and the rest remained in the upper floor until we turned them out from there.

26,907. The only case of suspicious plague in that neighbourhood is the one you have described as number 7?—The only suspicious case was that of the child.

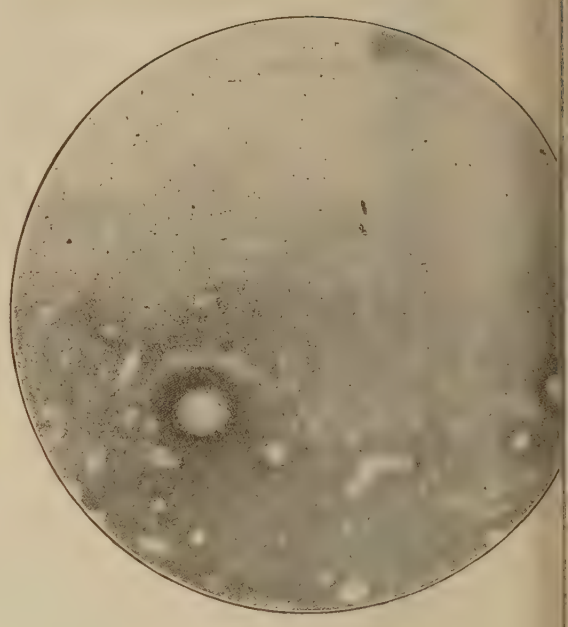
26,908. Will you proceed with the next case?—On the 3rd November, Bepin, an adult, working at a sugar factory, at No. 1 Raja Rajbullub Street, was reported to me by a native practitioner, Dr. Mukerji, as suffering from plague. Bepin had been attacked suddenly with fever, accompanied with severe head-ache pain, tenderness, and enlargement of the glands in the right groin. He soon became insensible, and died on the evening of 3rd November. Blood taken before death from vein in the arm, and from groin, showed diplo-bacteria, which were afterwards cultivated.

26,909. That is immediately before death?—Immediately before death. I have specimens of these cases. (*Handed to the President* (A, B, C)).

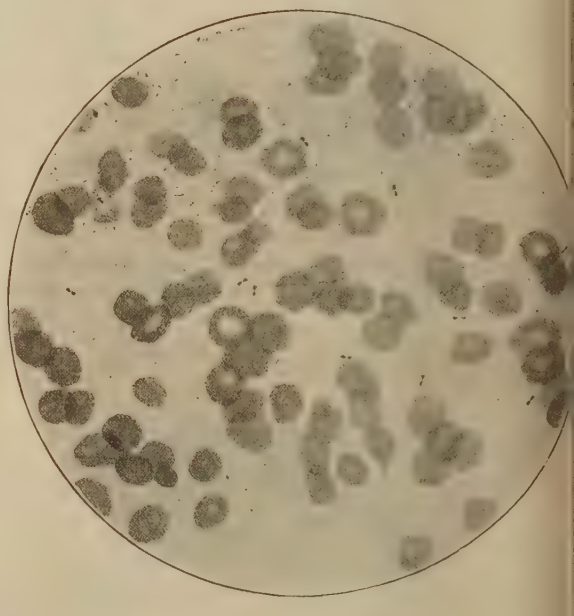
A.



B.



C.



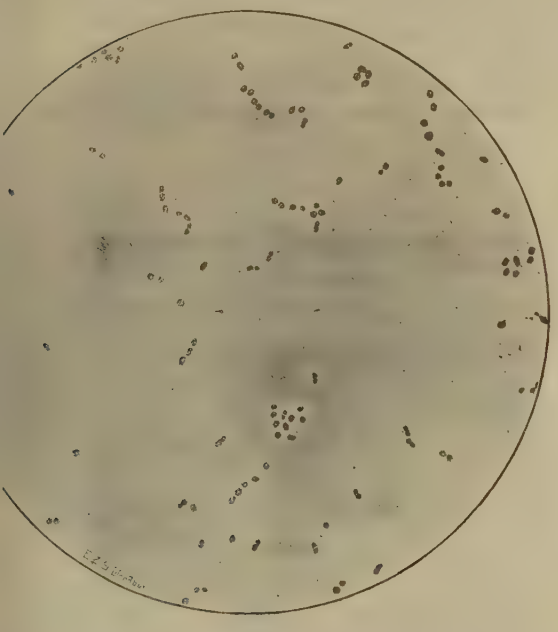
26,910. (*Prof. Wright.*) Are these drawings of cover glass specimens derived from that case?—No, not cover glass specimens in the case of the blood, but slide specimens.

26,911. Did you draw off the blood with a syringe?—No, not with a syringe. I had one of the sterilised pipettes which are used in the laboratory.

26,912. (*The President.*) Are these all magnified to the same extent?—Yes, one-fifteenth (Reichert). This

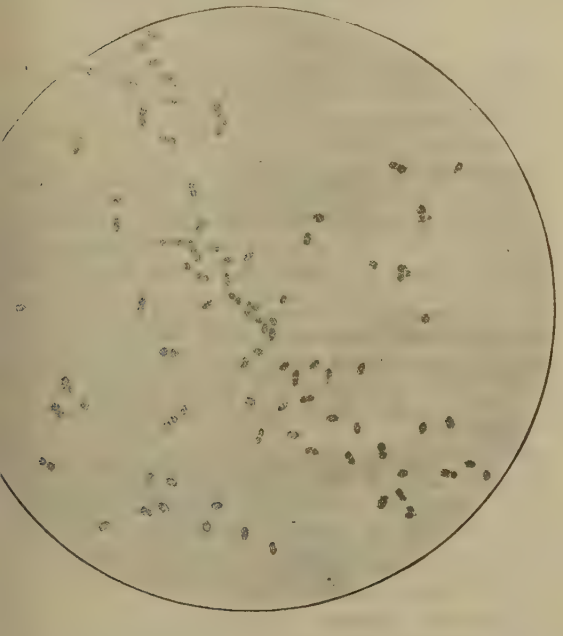
the appearance in the serum culture. (*Handing drawing to the President* (D)). They vary at times. At

D.



times they formed chains, while at other times they did not. This (E) is from a rat which was killed by 1 c.c.

E.



In another case 2 c.c. injected under the skin killed the rat.

26,913. (*Prof. Wright.*) Are these drawings of preparations which were made from rats killed with blood from Bepin?—Yes.

26,914. (*The President.*) Two c.c. is an enormous quantity, is it not?—Yes, it is; on the other hand 2 c.c. from the others already mentioned did not kill. My best specimens were, unfortunately, sent to Dr. Charles, and I did not get them back, so that I was not able to draw the specimens that were most characteristic.

26,915. Will you proceed with the next case?—On the 12th November I examined, along with Dr. Cobb, the dead body of a man named Marcellies, who lived in Bowbazar, and who was reported as having died of fever and glandular swelling. We found the axillary glands on one side much congested and swollen. I found organisms in that, but they were such that I could not give any opinion upon them. At one time they appeared to be of a similar kind, while actually later they came to be more like the streptococci of septicæmia. In December the Medical Board reported that none of the cases which had come before them were plague, but due to other causes.

26,916. (*Prof. Wright.*) All these cases were looked into by the Medical Board, I presume?—Yes.

26,917. (*The President.*) I want to make that perfectly clear. Each of these cases in human beings, which you have hitherto narrated came under the investigation of the Medical Board?—Yes.

26,918. Other cases investigated by the Medical Board did not come under your observation?—No, I do not think they were reported to me.

26,919. Will you state the next case?—In December 1896 a young girl, aged 16, living in a lane in Bowbazar, was treated for fever and glandular enlargements; the glands in both groins and in one of the axillæ enlarged, and after about a fortnight's illness suppurated. I saw the case with the medical attendant.

26,920. Did the case recover?—Yes, the case recovered, but it was tedious.

26,921. How near to each other were these two cases in Bowbazar; were the houses near to each other?—The two cases, Nos. 9 and 10, were not very far off from one another.

26,922. Have you any reason to suppose that there was any intercommunication?—No, I think not.

26,923. Did you ascertain that there could not have been?—No, but I may say that there had been a suspicious case of fever and glandular enlargement next door to No. 10. But I did not see the case, because the man had bolted by the time I visited the house.

26,924. Then will you give us the eleventh case?—About the same time two cases of fever, with glandular enlargement in one groin occurred in two boys, of one family, living in the southern suburbs of Calcutta. They were young boys about seven or eight years of age. The glands in the groin went on to suppuration.

26,925. Did you see the cases?—Yes.

26,926. What is the next case?—In January 1897 I saw a case of fever with glandular enlargement in the groin in a man who had arrived, a few days previously, from Singapore. He appears to have become unwell on the voyage; the disease corresponded in character with that in the Shropshire Regiment.

26,927. How long does it take to travel from Singapore to Calcutta?—A fortnight.

26,928. The man was already convalescent on arriving at Calcutta?—No, I do not think he was convalescent.

26,929. Did you see him?—Yes.

26,930. He had fever when you saw him?—Yes. The information I am about to give, I may say, is second hand. In January 1897 a large number of cases of fever with glandular swelling and buboes, some of which were fatal, occurred at Singapore.

26,931. What was your source of information? I understand it is the 21st Appendix to the First Volume of the Army Medical Reports, 1897?—That may be so, but I think I got it from the Singapore Reports. No satisfactory diagnosis appears to have been made. Active measures, however, for the segregation of the sick and the disinfection of the infected houses, were carried out. In connection with the occurrence of these suspicious cases it is to be noted that the Hong Kong authorities reported that undoubted cases of plague were brought to Hong Kong from Singapore. Some time in the early part of 1897, I was asked by the medical officer in charge of the Military Hospital at Alipore to see a native soldier who was ill with fever and glandular swelling of the parotid; also a boy in the same hospital, suffering from fever and a glandular

Dr. W. J. Simpson, F.R.C.S.

6 May 1899.

swelling in groin. Both were well isolated, and every care was taken of them. The soldier died.

26,932. Will you proceed?—A medical man in practice in Calcutta informed me that he had, in the early part of 1897, come across several cases of fever with glandular swellings, all of which got well.

26,933. What was his name?—Dr. Coulter. He is one of the European medical men in private practice in Calcutta.

26,934. Will you proceed with Number 14?—In February, according to the report of Dr M. J. Rosenau, the Quarantine Medical Officer to the Supervising Surgeon-General of the United States Marine Hospital Service, the British ship *Annie Maude* left Calcutta with three suspicious cases amongst the crew. The report is dated 16th July, and is as follows:—

" National Quarantine Station,
" Angel Island, California,
" SIR, " July 16, 1897.

" I HAVE the honour to report the British ship *Annie Maude*, 143 days from Calcutta, was placed in quarantine to-day for disinfection. A short while after leaving Calcutta one of the crew was taken ill with swellings in the axilla, groin, and elbow, and died. Two more of the crew suffered with buboes, from which they recovered.

" Very respectfully,
" M. J. ROSENAU,
" Passed Assistant Surgeon,
" U.S., M.H.S."

26,935. Can you tell me with regard to all these cases whether you have had any evidence to suggest infectivity or contagiousness among them?—No, I have had none.

26,936. You have had no evidence to show that they emanated from any previous cases of plague or disease of a similar kind?—None.

26,937. You have had no evidence to show that any of the rats which died communicated the disease, or that the disease had been communicated to the rats from human cases?—None.

26,938. With regard to your blood examinations, did you make any similar examination, following, as nearly as possible, the same procedure, in cases altogether free from suspicion of plague?—Yes. Dr. Cobb and I examined a number of healthy men and took blood from them, following the same procedure, using the the same apparatus, and the results were entirely negative.

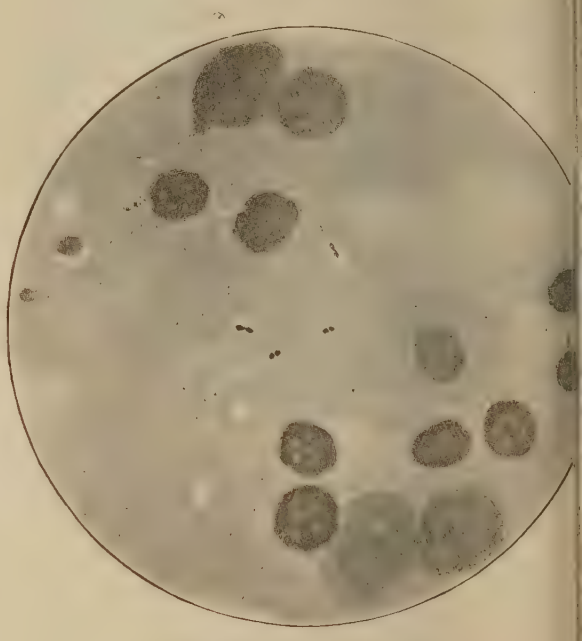
26,939. You found no organisms?—No organisms at all. I may mention that for years I have been examining blood in Calcutta. I am very much interested in vaccination, and also in the possible cultivation or discovery of an organism. During the process of trying several experiments, I have examined hundreds of cases of blood from children who have been vaccinated. I have also examined cases of patients who have had small-pox, and I have never seen any micro-organisms of this kind.

26,940. The procedure adopted in all these instances was the same as you have described?—Yes, very similar to that. It came to me as perfectly new to find that on the slide specimens there were organisms in these cases. It is supposed that the cultivations are all contaminations, but you cannot get an organism of that description which I have shown you in the slide specimens from the air.

26,941. What did you do to test that?—That is my opinion from a fair amount of experience. I have had slides specimens made in my laboratory over and over again, and had them exposed, and examined them afterwards, but have never found organisms. There is another point which I may, perhaps, mention to the Commission. I have been examining the blood of animals since 1894, with the object of seeing whether there were any organisms in the blood of those suffering from cattle plague. It was only in January 1897 that I found organisms in some cattle similar to those I have shown. There was an outbreak, very near the locality where the rats were dying. The cattle did not altogether suffer from the same symptoms which I had observed before in rinderpest. Some of the cattle evidently suffered from emphysema, with air passing into the tissues under the skin which made them look like stuffed animals. On examining two of these I found in the blood of these cattle, which were supposed to be suffering from rinderpest, organisms of a very similar character. On the *post-mortem* examination I found that the mesenteric glands were exceedingly congested and enlarged to a degree I had never previously seen.

26,942. You mean you found similar organisms to those in the rats—diplo-cocci?—Apparently diplo-bacteria (F). I have examined the blood of hundreds

F.



of cattle, both *post-mortem* and alive, and in the rinderpestic animals I have never found anything.

26,943. When did the cases occur in which you did find them?—In 1897.

26,944. At the same time?—A little later. They had the peculiarity which I have never found in rinderpestic animals, of the mesenteric glands being perfectly black, congested, and enormously enlarged.

26,945. Where had these cattle been kept?—They were kept in Calcutta, in some of the cattle-sheds which, I daresay, the Commission have seen, just a little north of the grain depôts.

26,946. You suggest that these cattle had also this disease, which you suppose to be plague—*pestis ambulans?*—I put that forward as a suggestion, but nothing more.

26,947. How many cattle did you see showing these symptoms?—There was an outbreak of the disease; I only examined, *post-mortem*, about three or four, and I examined the blood of only two in this way. Of course, these things only gradually dawn on one. I would not put it forward as more than an observation which, I think, is worthy of notice.

26,948. (*Prof. Wright.*) I understand you take each of these cases as being a probable case of plague. You have some grounds, in each case, for thinking it may gave been a case of plague?—Yes, I looked at it in this light; seeing there was plague in Bombay, and that these cases had cropped up in Calcutta, it was being on the right side to take precautions and endeavour to isolate them. That was the position I took.

26,949. I quite see the practical necessity for doing so. In the case of Cotta, the boy had buboes in the groin, had he not?—Yes.

26,950. And we may assume from that, may we not, that these bubos were due to some absorption of bacteria, either from the genital tract or from some wound on the surface of the skin of the leg?—Yes.

26,951. And in this particular case there is a history of sexual contamination, is not there? There is a definite history on that point, is there not?—It was not definite.

26,952. I thought you reported the presence of a rtain number of pimples on the *glans penis?*—Yes, it the glands had enlarged before that time.

26,953. I noticed that there was a disparity in that spect between your account and the account of the edical Board. You think you have a history of the ands having enlarged first, *i.e.*, on the 8th September. ow the sexual intercourse is said to have taken place the 13th, according to the Report of the Board?—es.

26,954. Further, if we take the history which you ve, it appears that these glands got worse simulneously with the appearance of "pimples" on the nis?—Yes.

26,955. Therefore, it is probable that some of the andular trouble was due to the absorption of septic atter through the penis?—It might be that.

26,956. Therefore, if this was a suspicious case of ague, it was at any rate a case which was complicated y septic infection from the penis?—Yes.

26,957. And further, unless it is absolutely clear om the history that the glandular swelling appeared efore the sores on the penis, it would be more natural regard the case simply as a case of sexual bubo?—es; the only thing is this, that our examination larmed people, and I think they naturally looked to omething else.

26,958. As an explanation, you think they might have nvented the venereal history to account for the preence of the bubo?—It is rather a hard thing to say hat, but I think it is possible. Three medical men nquired into the case, and the first thing we naturally hought of was syphilis, and both Dr. Tomes and Dr. Jobb made very minute inquiries concerning this aspect f the case. We discussed the matter thoroughly, and aving it in view that these glands were possibly due o syphilis, we were very particular in the history we ot from the patient. There was no mention whatever t that time of this sexual connection on the 13th September.

26,959. In the history, which was obtained by the Medical Board which examined the cases, it was recorded that Cotta was treated twice for soft chancres by Mr. Mitchell, the Assistant Surgeon?—Yes, but hey must have healed very rapidly, because I understand they were there only four days.

26,960. They are reported to have been better on the 4th, and you saw Cotta on the 9th. I do not know whether that account is correct?—He went on the 2nd and had an application, and they were better on the 4th. That is a very short time for them to get well.

26,961. But the principal point which induces you to believe that this was plague is the fact that you found bacteria in the cover-glass preparations of blood?—Yes, and the glands having enlarged before there was any venereal history.

26,962. Do you not think that general experience shows when you find bacteria in the blood in plague the case is a very serious one?—I know that is the general experience, but on the other hand, there is the experience of Kitasato. Kitasato found in 25 cases out of 28 the bacterium in the blood, and he states that it is found in cases of recovery. I have here a note from the "Twentieth Century," Vol. XV., which was written by Kitasato and another Japanese, Nakagawa. They described the two bacilli, and they say Yersin's bacillus is much larger than Kitasato's bacillus, and does not possess the distinctly diplo-coccus-like appearance of the latter. Owing to its polymorphism exact measurements are difficult to give. It does not possess a capsule. Yersin's bacillus is not mobile, and is decolorised by Gram's method. Cultural differences are equally conspicuous, on agar the growth of Yersin's bacillus is extremely luxuriant, and though the growth is rather slow at first, it continues for a week forming creamy white opaque colonies, projecting a good deal above the level of the surface of the media. Very young colonies are small and quite translucent. On the other hand, the colonies formed by Kitasato's bacillus are extremely delicate, transparent, small discs which attain the size of a pin's head and cease growing, and then disappear on the fourth day of incubation, presenting in all these respects a close resemblance to the growth of diplo-coccus pneumonia. Bouillon is not made uniformly turbid by the development of Yersin's bacillus; further, milk is not coagulated by the growth of Yersin's bacillus. The above-mentioned differential points ought to be enough to distinguish the one from the other. It is curious to observe that Yersin states that his plague bacilli (Y.B.) are found in the blood only of foudroyant cases, while Kitasato maintains that the bacilli (K.B.) can be found constantly in the blood; and further, that they may be found in the blood of convalescents for from three to four weeks after the symptoms have subsided.

26,963. At any rate it is the common opinion of bacteriologists that plague bacilli are only present in the blood in grave cases of plague, is that not so?—Yes, I admit that.

26,964. With regard to these other cases which occurred in the Shropshire Regiment, what opportunities do you think these men had for infecting themselves with plague? Did you bring the cases in any relation with the fact that these men had been in Hong Kong in 1895?—I only got my information second-hand.

26,965. And you learned, as a matter of fact, they arrived from Hong Kong on the 3rd January 1895?—Yes.

26,966. And these cases occurred in October 1890?—Yes, there were crops of them continually occurring from 1895 to 1896.

26,967. But in view of the fact that there was a continual crop of such cases recorded from the year 1892 onwards, and in view of the fact that non-venereal buboes are found all over India, do you think you can bring these cases into any relation with the fact that the regiment had served in Hong Kong?—Yes. I think Dr. Skinner's letter shows that these cases have not been continually occurring.

26,968. I have before me a record* of cases of inflammation of the lymph glands occurring in the troops in Calcutta from 1892 to 1896, and I find 29 cases recorded in the year 1892, 39 in 1893, 20 in 1894, and 42 in 1895?—I admit that, but I think possibly that these lymph cases may be similar to what occurred in England. There must have been some difference for the medical men to have taken notice of the cases that occurred in 1896 under Major Skinner, and the others.

26,969. You think these cases which occurred in 1896 were different?—I think so, otherwise why should they have been noticed at all? Why should the question arise? What are these cases? I have been looking into the Army Medical Report of 1894, and I notice that under the lymphatic and glandular system there were 11,000 admissions in England and 324 in Ireland, cases of a similar character. If these cases are so well known, how was it that it should attract the attention of the medical authorities at that time—in 1896—as being something peculiar, not knowing the cause; because first of all on the tickets of these cases they are marked "syphilitic," afterwards they are marked "malaria," and still later "unknown"? I think that very fact indicates that these cases which occurred in the Shropshire Regiment must be different from those which are commonly noticed elsewhere, and which were so common in the army under this particular classification.

26,970. We have had Major Skinner's evidence on that point, but we want to supplement his evidence by your evidence on the bacteriological facts. I understand you made cultivations from two of these cases, one, the case of the man Rabbid, and the other the case of Finney?—Yes.

26,971. You inoculated 12 tubes from each of these men?—Yes.

26,972. We have it from Major Skinner that all these tubes remained sterile except one; is that accurate or inaccurate?—It may have been so, but I could not say the exact number. I think there were one or two that gave this organism, but I would not be certain up on that.

26,973. Still, the large majority of the tubes you inoculated remained sterile?—Yes.

26,974. (*The President.*) There were 24 tubes in all and no growth appeared except, possibly, in two?—Two or three of each set, but the majority of them remained sterile.

26,975. (*Prof. Wright.*) How do you, in view of the fact that these drawings which you have put in, show 2, 2, and 5 bacteria respectively in each field, account

* *See* App. No. XXI. in Vol. I. of these Proceedings.

Dr. W. J. Simpson, F.R.C.S.

6 May 1899.

for the fact that bacteria did not develop in each of the tubes you inoculated with this blood?—I mentioned that I took a large number of slide specimens, and it is only in one or two that I found this.

26,976. It was not in every field that you found bacteria, but only in a very few of the fields?—That is so.

26,977. Did you find bacteria in each cover glass?—No. By examination we found them in one or two specimens of each.

26,978. (*The President.*) Supposing you had one cover glass in which you found them, does that mean that they were found in only one field of the cover glass or several fields?—It was not a cover glass specimen, but a slide specimen.

26,979. One part only, or in many parts?—Not in many parts on one slide. I have had that drawn. That was the only one found on that particular slide.

26,980. (*Prof. Wright.*) Do not you think there it would be quite possible to find that number of contaminating micro-organisms on every slide?—I hardly think that it would repeat itself so frequently.

26,981. In view of the fact that diplo-cocci, such as you figure here, are very frequently met with in the earth in Calcutta, do you not that it is very probable these diplo-cocci which you figure may derive from contamination?—I hardly think so. Of course, if they had fallen on the ground it might be a different matter, but seeing they were put into a box and taken to the laboratory at once and examined, I do not think that could be so. I will not say it is an impossibility, though, personally, I do not think it is possible for a fully cultivated and regularly formed organism to alight from the air on to a slide. I do not wish in any way to press my views on the Commission. I want it to be understood that what is really wanted is truth. I have no bias one way or the other. Having met with these organisms, I am not attached to them.

26,982. In view of the fact that these cases occurred 18 months after the regiment came from Hong Kong and in view of the fact that so few bacteria were found in the blood I ask you whether it did not suggest itself to you that possibly these buboes had nothing whatever to do with the plague?—You must remember that although it was 18 months after the regiment came from Hong Kong there were continuous crops of cases recurring and that it was only the last ones which were ill which were examined.

26,983. Do you adhere to your opinion that these cases may have been cases of plague in view of the fact that these cases occurred not only in the Shropshire Regiment, but also in the Artillery, which has never been in Hong Kong?—I think the very fact that these cases occurred after the Hong Kong Regiment reached Calcutta shows that there is no reason why they should not also occur in the Artillery which were in close association with them.

26,984. That applies only if it can be shown that these cases among the Artillery did not occur also before the Shropshire Regiment arrived?—Yes. But what has struck me is this, that these lymph glands are so common in England and elsewhere that they must be well-known to Major Skinner and to others, and yet medical men came to the conclusion that very year that these cases might be venereal, might be malarial, or might be due to an unknown cause. They were cases that attracted attention and puzzled the medical men. It seems to me there was something different from what was usually met with.

26,985. I take it, in view of the evidence that we have already had from Major Skinner, that the facts did not present themselves to his mind in that light?—I think he says attention has been directed to it for certainly a year past.

26,986. Is there a single case among those which you have reported in which it appears to you to be absolutely established that you were dealing with a case of plague, or is your opinion that you were dealing with plague, based upon a general survey of all these cases? Are there any of these cases in which you obtained the plague bacillus in pure culture?—Yes, I think there can be little doubt that Giga, the child attended by Dr. Charles, was a case of plague; that Golab was a case of plague; and that Bepin was a case of plague; and I think, taking a general survey of the other cases, that most of them were probably mild cases of plague. I obtained the plague bacillus in a pure culture in the case of Bepin, and in 1897 I took the culture to M. Haffkine, when I was leavin India, and he examined the tube and said the growt was suspicious. He also examined the microbe micr scopically and said it was very much like the plagu bacillus. Then he subjected the bacillus to the stala tite test, but, unfortunately, it did not grow—apparent the culture was too old.

26,987. (*Mr. Cumine.*) Of the cases which you kne of, and thought to be plague in 1896, how many died —I mentioned Bepin's case and then I mentioned tha of Golab.

26,988. I mean what proportion died?—I have n worked out the proportion but they were exceedingl few. I did not go on the mortality.

26,989. If it had been really plague would not large proportion have died?—Not necessarily. I hav known instances where a large proportion have no died even in the Bombay Presidency. There was th outbreak which was reported by Dr. Dyson in Kosumba in the Bulsar Táluka, where three-fourths of the case were very mild. He reports that: "The disease was o "a mild type, characterised by slight fever of two o "three days' duration and the formation of buboes "chiefly in the groin. Fully three-fourths of the 3 "cases which occurred were of this type, and during "one visit to the village I found two boys, about 1 "years of age, with buboes in the groin, whose feve "had been so slight as to escape observation, and "they had not been recognised as cases of plague." You get different types of plague. Then there are well-known cases which were suspected to be plague in Astrachan† in 1877; there were 150 to 200 person attacked without a single death. There was also the epidemic of plague at Resht‡ in which two forms o the disease were noticed, a severe and mild form. O the former, who mostly died, there were about 170 There were about 600 mild cases which nearly all recovered.

26,990. Did any of those cases which you thought was plague produce any infection in the neighbourhood?—No, I was not able to trace any infection.

26,991. Or amongst the people who attended the sick?—No.

26,992. (*The President.*) Can you give us the reference to the statement made about Astrachan?—I think it is in the Medical Officer's Report for 1879, to the Local Government Board. I will send the exact reference to the Commission.†

26,993. (*Mr. Cumine.*) Did you attempt to see whether the bacillus, which you thought was plague bacillus, could be obtained from the blood of healthy animals, such as fowls?—No, I did not. I tried with rats. I examined 12 rats to see if they contained any bacilli.

26,994. Did you see the bacillus which Dr. Cunningham obtained from the blood of a healthy fowl?—No, I was not favoured with that.

26,995. You do not know whether that exactly resembles the one which you found?—No.

26,996. Were all the specimens of the supposed plague bacillus found by you exactly alike? Did they all resemble one another?—They seemed very much alike in character. Culturally, they did not go on alike. Sometimes they were of a more coccoid form—egg-shaped bacilli amongst them—and at other times they seemed to go into chains, and others were diplo-bacteria.

26,997. In the case of the lad Cotta, does not Dr. Dyson report that the local sores were noticed on the boy on the 17th, and that the swelling of the glands occurred on the 19th?—Yes, there is a discrepancy between the result of his inquiry, and the result of ours.

26,998. Were the symptoms of the boy Cotta such as one finds in plague? Dr. Dyson, for instance, says that his appetite was good, his tongue was clean after nearly a month's illness, that he never suffered from frontal headache, delirium, high fever, hæmorrhage, or epistaxis, or injection of the conjunctiva, that the enlarged glands have never caused severe pain, and, in

* *See* "Account of Plague Administration in Bombay Presidency; from September 1896 till May 1897," prepared by Mr. E. Couchman, I.C.S., page 244.

† *See* Report of the Medical Officer to the Local Government Board, for 1879, p. 49.

‡ *See* Tholozan, "Comptes Rendus," 1877, p. 432.

fact, that he has had none of the classical symptoms of plague. Do you admit that description of the symptoms as given by Dr. Dyson?—Hardly. I think there are varieties.

26,999. Are these symptoms of the boy Cotta correctly described?—Yes.

27,000. Are these symptoms compatible with his having had plague?—Oh, yes, I think so. For that reason I would mention what is stated by Dr. James in his report on the Hong Kong epidemic, which appears in the Army Medical Department Report for 1893. In Appendix No. 5, he states, on page 331, that the disease is endemic in the province of Yunan, and cases occur every year, those attacked having buboes, but very little constitutional disturbance, and all recovering. On page 335, he mentions that some of the soldiers employed in the working parties became affected, and some who were not so employed, and an officer, Captain Vesey, of the Shropshire Regiment, was taken ill early in June of plague and succumbed. On p. 348 he states that in abortive plague the bubo occurs without fever. Similar cases to those in Yunan occurred in Mesopotamia. I think it was Dr. Tholozan, in his work on plague, who mentions that from epidemic to epidemic the bridge is filled up by these mild cases of plague, which produce very little constitutional disturbance. Dr. Dickson, at page 55 of the Report of the Medical Officer for 1879 to the Local Government Board, describes the prevalence of *glandular swellings free from fever* two or three months previous to fatal plague in Hillah and Bagdad, and on the cessation of plague *apyretic glandular swellings* reappeared again for two months longer.

27,001. Can you give us the authorities for the statement about Yunan?—Major James mentions it in his report on Hong Kong.

27,002. Do you know who was his original authority?—No. Possibly Dr. Tholozan's work would give some of these mild cases of plague.

27,003. (*The President.*) Do you know the title of that?—May I be allowed to send the reference to you. (Note by witness on correcting proof of his evidence: "La Peste en Turquie dans les temps mo- "dernes, sa prophylaxie defectueuse, sa limitation "spontanée.")

27,004. (*Mr. Cumine.*) In the case of the boy Tincauri Pal, was there any history that before his becoming ill on this occasion he had now and then suffered from fever and cold and swelling of the inguinal glands?—I did not discover a history of that kind.

27,005. With regard to these climatic buboes, that is to say, buboes such as were seen in the Shropshire Regiment, have they been noticed to any large extent and for a long time on the East Indian station, and to a lesser extent on the Mediterranean and China station?—Yes. It is stated that cases like that have been reported. I remember that Surgeon Godding, of the *Centurion*, wrote a paper* in the *British Medical Journal* on climatic buboes, and gives instances. The peculiarity of his instances was the fact that they were seamen who were stationed at Hong Kong at the time of the plague.

27,006. He says: "I have myself seen the worst "cases on the East Indian station at Zanzibar and "adjacent coasts, the patients having huge masses of "glands in the groin often suppurating, producing "anæmia and debility"?—That is among the seamen at Zanzibar. Many of the ships that go to Zanzibar, go also up the Persian Gulf, and have communication with those places where, I believe, these buboes occur frequently. I was speaking to a medical man who had been in Bagdad for a number of years, and he stated that every year there were a few cases of glandular swellings.

27,007. (*The President.*) They were supposed to be cases of mitigated plague?—Yes, so that I do not think much importance can be attached to these cases being affected at Zanzibar, considering that those affected most likely visited the region where cases occur.

27,008. (*Mr. Cumine.*) Does he not say they occurred also, though less frequently, in the Mediterranean, Australia, and the West Coast of Africa?—I think it is very likely that they would occur, though possibly not the same disease as the glandular swelling in plague infected areas. The difficulty is to differentiate the one from the other, unless special attention is given to each, and the several likely causes investigated.

27,009. (*The President.*) I gather that your chief reason for believing these cases to be a form of plague was the microscopical examination?—Partly microscopical and partly for other reasons. In Giga and Bepin, the symptoms are, to my mind, after my experience in Bombay and Poona, typical plague, such as may be seen anywhere in a large epidemic, and, similarly, though more obscure, are some of the others. The death of the rat with swollen glands in the house of Giga and similar micro-organisms being found in the child and rat strengthened this opinion, also the rats dying to such an extent in the grain depôts, and having very similar micro-organisms in their organs.

27,010. Your cases do not illustrate any power of infection at all?—I have not noted any.

27,011. You have made inquiries in that direction?—Yes.

27,012. You did not find it in any case?—No; they seemed to be dotted about. A similar discussion took place, I believe, with reference to the appearance of an illness with glandular enlargements when the Pali plague broke out in 1836. Doctor Forbes, who investigated the cases, came to the conclusion that they were a mild form of plague. It was stated at the time that cases of a similar nature were common and due to malaria, but his investigation indicated that the illness appeared some time before plague broke out, and the cases were connected with plague and not malaria. He made very particular inquiries of native medical men as to the prevalence of buboes after malarial fever, and they did not know of cases at that time; subsequently they met with them.

27,013. In regard to the cases in which cattle appeared to have suffered from something like plague, are you aware that in India, generally, cattle often live in the same houses as human beings?—Yes, that is so.

27,014. In many instances these houses contain plague-affected human beings?—Yes, in the hills.

27,015. Not only in the hills, but, in the villages in the plains?—Yes.

27,016. Do you know if anything similar to plague has occurred among these cattle in India in any city outside of Calcutta?—No, I have not read of any. I have watched the cases with that view, but nothing has come to my notice. Dr. Weir records that there was a great mortality among cattle in Bombay in the middle of 1896.

27,017. Very virulent forms of plague have occurred in human beings in houses in which cattle have been kept?—Yes.

27,018. There appears to be no evidence that these cattle have ever taken the plague?—None has been collected.

* *See* App. No. XXI. in Vol. I. of these Proceedings.

(Witness withdrew.)

(Adjourned till Saturday, 20th May.)

At The India Office, Whitehall.

SEVENTY-SECOND DAY.

Saturday, 20th May, 1899.

PRESENT:

PROF. T. R. FRASER, M.D. LL.D., F.R.S. (*President.*)

Mr. J. P. HEWETT, C.I.E.
Professor A. M. WRIGHT, M.D.

Mr. A. CUMINE.

Mr. C. J. HALLIFAX (*Secretary*).

Captain H. D. MASON, R.A.M.C., called and examined.

Capt. H. D. Mason. R.A.M.C.

20 May 1899.

27,019. (*The President.*) What are your medical qualifications?—I am M.R.C.S.

27,020. What was the appointment which you held in India?—I was on plague duty under the Government of India, in the Cutch State.

27,021. You were in the Cutch State during the time of the plague epidemic?—Yes.

27,022. And you had an opportunity of seeing many cases treated by ordinary methods?—Yes.

27,023. And many also treated with serum?—Yes.

27,024. I think of each group you have tabulated 100 cases?—The cases given in my précis were one typical hundred of each—one hundred taken out of many. Each group of cases was taken under exactly the same conditions, 100 being treated by ordinary methods, and 100 with the serum antipesteux. Both series were taken between the first and the fourth day, and the two have been contrasted with each other.

27,025. These cases were not selected for any special reason?—Not the least in the world, they were treated exactly as they were admitted.

27,026. And the gravity of the illness?—Had nothing whatever to do with it. In some cases we did make a distinction at first. Those who died in the first 24 hours were eliminated. In these lists we thought that the cases which died in the first 24 hours should be included, and that has been done.

27,027. You have included them all in your tables?—Yes.

27,028. Will you put the tables in?—Yes, they are as follows:—

ONE HUNDRED CASES of PLAGUE TREATED by ORDINARY METHODS in the BRAHMAPURI HOSPITAL, CUTCH MANDVI.

Cases admitted between first and fourth days (four after or unknown).

No.	Name.	Sex.	Age.	How long Ill.	Admitted to Hospital.	Buboes.	Result.

99	Hirabai	„	25	3 „	„	„ „	Died.
100	Hadhubai	„	35	2 „	2nd June	„ groin	„

In cases treated by ordinary methods the prognosis is better in children than men and in men than women.

Of 260 deaths in the Brahmapuri Hospital (Hindus) there were :—

Children under 10	25
Males	89
Females	146
Total	260

Whilst in 3,516 deaths from all hospitals, there were :—

Children	563
Males	1,226
Females	1,727
Total	3,516

The healthy and robust appear not only prone to contract the disease, but to suffer from the most virulent forms, and die in as great a proportion as those of weaklier frame and less sthenic constitution.

The epidemic at Mandvi was at its height in May and June. The non-inoculated cases were collected in May and June. The inoculated cases treated in the Mandvi Brahmapuri Hospital in May and June are comparable.

The epidemic at Gundiali town was at its height in August and September. The inoculated cases treated there during that time are comparable to the non-inoculated cases treated in the Brahmapuri Hospital in Mandvi when the epidemic was at its height there. The same applies to Merau village.

The cases treated in the various hospitals are bracketed.

Capt. H. D. Mason, R.A.M.C.

20 May 1899.

CASES of PLAGUE treated with SERUM ANTIPESTEUX in CUTCH MANDVI.

	No.	Name.	Sex.	Age.	Admitted to Hospital.	How long ill when injected.	Total Quantity Injected.	Result.	Bubo.	Remarks.
Brahmapuri Mandvi.					1897.			1897.		
	1	Nursey Jiva	M.	9	30.5	4 days	90 c.c.	Discharged	Parotid, left groin, left cervical.	
	2	Jayanak	„	35	„	„	105 „	Died 4.6	Right axilla.	Not injected till 4th May.

27,029. Will you briefly state the results?—In contrasting the cases treated by serum and those treated by ordinary methods it will be seen that out of 100 cases of the former 59 died and 41 recovered; of the latter 83 died and 17 recovered.

Capt. H. D. Mason, R.A.M.C.

20 May 1899.

27,030. What is your opinion as to the value of the serum antipesteux which you used?—I think it is of the greatest value in all except the very gravest cases. On those, apparently, it had very little effect—those who came with the most marked symptoms of plague, marked delirium, high temperature, continuous vomiting, &c. On those, as I say, it seemed to have little or no effect, but in the milder cases, undoubtedly, it produced a favourable effect.

27,031. As contrasted with the ordinary treatment?—Yes, I do not think the ordinary methods had any effect at all—not the slightest effect in the world.

27,032. Your percentage of recoveries is considerably better with serum than without it?—Yes.

27,033. What serum did you employ?—The serum prepared by Dr. Roux, of the Pasteur Institute.

27,034. Could you state generally what were the doses that you used?—They varied. Of course, with us it was quite an experiment. It had never been used before, except a little in Bombay, and when it came to us we used it in small doses at first—10 c.c. and 20 c.c.—but afterwards in very much larger doses, up to 60 c.c.

27,035. Are you able to contrast the effects of the smaller doses with those of the larger doses?—It is quite possible that I could, but I cannot from these tables. I had every case which I treated entered in books, but without going through these books I do not think I can contrast the effect of the smaller doses with the larger. But, roughly, I should say that the larger doses were more successful than the smaller ones, because it was that fact which led us to use the larger doses.

27,036. The smaller dose was not so satisfactory as the larger one?—No.

27,037. Perhaps, as you have the data, you could put them into some statistical form for us?—I will endeavour to do so when I go back.

27,038. We want you to contrast as nearly as you can the larger with the smaller doses?—The following figures give the required comparison :—

	Cases.	Deaths.	Recoveries.
Small doses (60 c.c. and under) -	14	7	7
Large doses (over 60 c.c.) - -	86	52	34

In the recrudescence I have a certain number of cases which were treated by very large doses in certain caste hospitals, and those were very curious. Amongst the Muhammadans 9 out of 18 recovered, but among the Bhatias we only injected the serum in six cases, and every one of them died.

27,039. Were the latter treated by larger doses?—Yes.

27,040. The result was not altogether satisfactory even with the larger doses?—It was among the Muhammadan caste, but not amongst the Bhatias.

27,041. Have you any explanation of that?—Nothing more than the general explanation, that the Hindus are a much feebler class of men; they are vegetable eaters. The Muhammadans have much greater vitality and finer physique altogether. Whether that is any explanation or not I am not prepared to say.

27,042. On the whole, the doses with which you treated these several groups were much the same?—Yes. You will see in the following table, of the 18 Muhammadans inoculated 9 recovered, and that every one of the Bhatias died. The following is the table I refer to :—

Cases inoculated with Serum Antipesteux at Caste Hospitals during Recrudescence of 1898.

Name of Hospital.	Admissions.	Inoculated.	Discharged.	Died.
General - - -	—	35	10	25
Banniah - - -	—	1	0	1
Bhatia - - -	—	6	0	6
Muhammadan - -	—	18	9	9

I remember distinctly that all these cases were very serious indeed, and which would certainly not have got well with any ordinary treatment.

27,043. Do you mean in the four groups?—No, in the Bhatia group.

27,044. Then it would be a mere question of individual resistance to the severity of the illness?—Perhaps so. The reason I remembered these cases was that we had great difficulty in getting the Bhatias to be inoculated. We were very confident of the result after inoculating the Mahommedans, and we did what we could to get the Bhatias inoculated. But, unfortunately, every one of them died, and, therefore, we did not think it wise to go on after that on account of the feeling it produced in the caste.

27,045. At what stage in the illness did you commence the treatment?—As soon as ever we could get them. The earlier the inoculations the better the results.

27,046. You commenced between the first and the fourth day?—Yes, after the fourth day it was hopeless. The patient either got well in that time or it was hopeless.

27,047. How many doses did you inject in each case?—They also varied according to the results of the temperature charts. The temperature charts were all taken, and with a big fall the indication was not to continue the treatment, but directly the temperature began to rise we gave another large dose. As soon as the temperature went up we gave three or four inoculations.

27,048. Taking the cases generally, how many injections did you make?—That I cannot tell you without the temperature charts. I much regret that I did not bring them with me.

27,049. Perhaps you will send them?—Yes.* You will see that on each fall of the temperature the amount of the injection is given above the fall, that is to say, if the temperature went up to 104°, on the top of the 104° the amount of the inoculation would be registered, and if it came down again—wherever it was given on the temperature chart—the amount was registered on it.

27,050. What was the most conspicuous beneficial effect which you observed?—The fall in the temperature in the first place, and the general condition altogether. For instance, the patient who came in delirious became calmer, the temperature fell, the vomiting stopped, and there was general amelioration of the condition.

27,051. Were those good results obtained in cases which afterwards died as well as in cases which recovered?—Yes.

27,052. It was an almost invariable consequence of the injection of the serum that the temperature fell?—No, I could not go so far as to say that. I had cases which were treated with ordinary methods where the temperature also fell. It is certain that in ordinary cases the temperature falls under the action of the first injection, and it is equally certain in many cases it never re-ascends. This fall in temperature is obtained whatever the day of the disease on which the treatment is commenced. The most characteristic signs of the beneficial influence exerted by the serum are: fall in temperature; amelioration of the general condition; diminution of stupor and improvement in prostration. The improvement in the general condition, like the fall of temperature, is, in the majority of the gravest cases, apt to be transitory; the symptoms again become serious, and the disease appears to run its course as if the serum had not been given.

27,053. Did you find that the beneficial effects were most likely to be obtained if you commenced the treatment early?—Yes, the earlier the cases are treated the more is the intensity of the symptoms and the progress of the disease diminished. In cases which appear certain to die, the course of the disease seems to be stayed, and even if recovery does not take place, it nevertheless provides a most powerful resistance to the disease, and one which may last a considerable time. That remark was made on account of a very serious case which came in and which seemed to be kept alive by the administration of serum, and which eventually died. That was one case among others.

* *See* App. No. LXXXV. in this Volume.

27,054. What is your general conclusion?—I submit at if the treatment by serum is ineffective in a cer-in number of the worst cases it has an enormous ower over those where the toxine poisoning is not of e gravest, and where the disease does not run its ost rapid course. In these cases we are bound to mit that the recovery is due to the serum.

27,055. Is it your opinion that if you could have ven larger doses the results would have been still ore satisfactory, or do you think you attained the aximum dose which it was requisite to administer?— at is a difficult question to answer. The reason we d not give any larger doses was because in certain ses a kind of synovitis developed in various joints— the elbows and wrists, and it was doubtful whether is synovitis was part of the plague itself or whether was produced by the large doses of serum adminis-red. That is why the doses were not increased.

27,056. Did these large doses have much effect on e heart so far as you observed?—No, I have no servation to that effect.

27,057. You have taken the pulse rate?—Yes, they e all recorded—the pulse, the temperature, and spirations.

27,058. These do not show that any effect was pro-uced by the large doses of serum?—As far as I member, no.

27,059. Was there much local effect produced at the at of injection?—None whatever.

27,060. Even by the maximum dose?—None what-ver.

27,061. What was the maximum single dose?—I went p to 60 c.c.

27,062. Even 60 c.c. produced no local disorder?— ot the slightest.

27,063. No complaint of pain?—There was a certain mount of pain, of course.

27,064. The swelling subsided spontaneously and pidly?—Yes.

27,065. I see you have also made some experiments n animals. That is with the same serum, I presume?—Yes.

27,066. What animals did you use?—Mice, rats, nd two monkeys.

27,067. Will you put those experiments in?—Yes.

EXPERIMENTS ON ANIMALS made with SERUM ANTIPESTEUX (No. 31).

(I.)

Mouse No. 1.—Inoculated with plague culture under ot of tail, 5 minutes after received $\frac{1}{50}$ c.c. serum.— esult, died in 3 days.

Mouse No. 2.—Inoculated with plague culture, 5 inutes after received $\frac{1}{40}$ c.c.—Recovered.

Mouse No. 3.—Inoculated in same manner, 20 hours fter received $\frac{1}{10}$ c.c.—Died in 90 hours.

Mouse No. 4.—Inoculated in same manner, 20 hours fter received $\frac{1}{3}$ c.c.—Recovered.

Mouse No. 5.—Inoculated in same manner.—Received o serum, died in 42 hours.

(II.)

Mouse No. 1.—Inoculated with blood of a rat dead of lague, 20 hours after received $\frac{1}{4}$ c.c.—Died in 7 days. Neither examination of organs nor cultures showed lague bacillus, nevertheless there was reason to believe eath due to plague.

Mouse No. 2.—Inoculated in same manner. Received o serum.—Died in 60 hours.

(III.)

Mouse No. 1.—Inoculated with lymph from a human lague pustule containing enormous numbers of acilli, 24 hours after received $\frac{1}{3}$ c.c. serum.—Recovered.

Mouse No. 2.—Inoculated with same lymph. Re-eived no serum.—Died in 76 hours.

SERIES made with SERUM (No. 88).

Capt. H. D. Mason, R.A.M.C.

20 May 1899.

(I.)

Mouse No. 1.—Inoculated with culture from human bubo, 20 hours after received $\frac{1}{4}$ c.c.—Recovered.

Mouse No. 2.—Inoculated in same manner. Received no serum.—Died in 72 hours.

(II.)

Rat No. 1.—Inoculated by subcutaneous injection with $\frac{1}{20}$ c.c. of the blood from the heart of a mouse dead of plague, 24 hours after received 2 c.c. serum.—Recovered.

Rat No. 2.—Inoculated in same manner. Received 36 hours after 2 c.c. serum.—Died in 96 hours.

Rat No. 3.—Inoculated in same manner. Received no serum.—Died in 71 hours.

(III.)

Monkey No. 1.—Received by subcutaneous injection the half of a mixture made by crushing up in 2 c.c. of sterile water the spleen, heart, and liver of a mouse which had died of very virulent plague, into the right thigh:—

After 12 hours.		An enormous femoral bubo appeared.
,,	18 ,,	High fever, walked with difficulty, and refused food.
,,	24 ,,	Received 2 c.c. serum.
,,	49 ,,	Not much change, difficulty in walking increased.
,,	,, ,,	Second injection of 20 c.c. serum.
,,	66 ,,	General improvement.

On the 4th day began to eat again, bubo increased in size, commencing to break down.—Complete recovery, 10th day.

Monkey No. 2.—Received same quantity of same preparation at same time:—

After 12 hours.		Bubo in right thigh.
,,	24 ,,	Fever less marked than No. 1.
,,	36 ,,	Difficulty of walking increased.
,,	48 ,,	Could scarcely move.
,,	66 ,,	Died.

27,068. In the first group of experiments you gave the serum first?—Yes.

27,069. How many experiments did you make?—There were five.

27,070. How many died, and how many recovered?—Two of them died, and three recovered.

27,071. Did you have any control experiments to show the quantity of the plague virus which would probably have killed each of these animals, without the serum?—Yes; Nos. I 5, II 2, III 2.

27,072. Did you satisfy yourself in each of these cases that a lethal dose of plague virus had been administered?—Yes, certainly.

27,073. Did you give much above the minimum lethal dose?—That I cannot say.

27,074. You have no idea what the minimum lethal dose of the virus may be?—No.

27,075. Then how can you say that it was above the minimum lethal dose?—It was sufficient to kill those that received no serum.

27,076. It might be that some of these recoveries were not due to the serum at all, but to the fact that the dose had not been a lethal dose?—Not probable.

27,077. It seems a fundamental requirement that that should be shown?—Yes, it does.

27,078. The next series you made was where the serum followed the administration of the virus?—Yes.

27,079. They were actually therapeutic experiments, I think; that is to say, the treatment followed the reception of the virus?—Yes.

27,080. Did you make many of that description?—No, not many.

27,081. How many did you make in the case of mice?—Three.

27,082. What were the results of these experiments?—The greatest result was that the administration of the

Capt. H. D. Mason, R.A.M.C.

20 May 1899.

serum either prolonged the existence of the animals, or that they recovered.

27,083. The first two died?—Yes.

27,084. Only one recovered?—Yes.

27,085. You do not state how much of the virus you gave in these cases?—No.

27,086. You did make an attempt, no doubt, to give a similar quantity. How did you weigh the virus? How much did you give of the culture, for example?—At the time these were done, we had no notion what the lethal dose was by actual measurement.

27,087. I thought that for any given virus you might have roughly ascertained what the lethal dose was. You did not do that?—No.

27,088. In the next series, you made some experiments on rats; three experiments?—Yes.

27,089. There were actually two experiments with serum?—Yes.

27,090. One died, and one recovered?—Yes.

27,091. You state that one-twentieth of a c.c. of blood was used in the first instance?—Yes.

27,092. How much did you use in the second instance? Was it done in the same manner, with the same quantity?—Yes.

27,093. And the same blood?—Not exactly the same manner.

27,094. But was it exactly the same blood as the first of these experiments?—Yes.

27,095. And the same dose?—Yes.

27,096. Perhaps you had better put that more definitely when you correct your evidence. The "same manner" does not quite cover the whole of the conditions?—I will do so. (Note by witness on correcting proof of his evidence:—All three rats were inoculated by subcutaneous injection with one-twentieth c.c. of the blood from the heart of a mouse died of plague.
No. 1 received 2 c.c. serum 24 hours after inoculation.
No. 2 „ „ „ 36 „ „ „
No. 3 „ no serum).

27,097. In the third experiment, I presume you gave the same blood?—The same dose and the same blood.

27,098. And the animal died?—Yes.

27,099. How do you explain the death in the one instance, and the recovery in the other, if the conditions of the experiments were absolutely the same?—Because one of them received the injection 24 hours afterwards, and the other 36 hours afterwards.

27,100. That certainly makes a considerable difference?—Yes.

27,101. They were not exactly comparable?—The time in which the one received the serum was earlier than the other.

27,102. How many experiments on monkeys did you make?—Only two.

27,103. What were the experiments?—The mixture was divided into two, and an equal part was given underneath the thigh. The mixture was made by crushing up the spleen, heart, and liver, of a mouse which died of virulent plague.

27,104. By subcutaneous injection?—Yes, injected into the thigh.

27,105. In the first experiment, you gave 2 c.c. of serum 24 hours afterwards?—Yes.

27,106. What was the result?—The results are all stated in the details which I have put in, and the symptoms which were produced on each inoculation are given.

27,107. In the second experiment the monkey received the same dose of virus?—Yes, without any serum at all; he got gradually worse.

27,108. The monkey died in 66 hours?—Yes.

27,109. What were the weights of these monkeys?—I cannot remember that, they were the ordinary "Guzarati" monkey.

27,110. They did not differ much in weight?—No, they are both exactly the same size.

27,111. You think they were about the same size?—Yes.

27,112. That question of weight would make a considerable difference. If there was much difference in the weight of the animals, the results can hardly be compared?—The monkeys were not weighed, but they were of the same class.

27,113. You know, roughly, they were about the same weight?—Yes.

27,114. Therefore, they are probably comparable?—Yes.

27,115. So far as they go, these experiments seem to indicate some curative power?—Yes.

27,116. You gave, in all, 22 c.c. of serum?—Yes, a small dose at first, and then a big one when he began to get worse.

27,117. You have had some opportunities of observing the effects of segregation, I believe?—Yes.

27,118. Will you describe what the segregation consisted of?—All the ports of Cutch were closed to passengers, except Cutch Mandvi and Khari-Rohar. At Mandvi no steamer was allowed to disembark between 6 p.m. and 6 a.m. All passengers from Bombay and Karachi were taken direct to the segregation camp on the Bandar through an alley way specially railed off. The age, caste, father's name, place of departure and destination of each passenger was taken and registered. The register was called over at uncertain times to see that all passengers were present. The method for the disinfection of clothing consisted in boiling in large copper vessels, and, in the absence of any special dry air or steam apparatus, was found very efficacious. Perishable articles likely to be destroyed by boiling were exposed to the sun daily. It was only at Cutch Mandvi that the people were segregated, that is where they were thoroughly segregated. Khari-Rohar was not under my supervision, and I am not aware what was done there. I believe the people were segregated in a rough manner, but there was no stringency whatever about the rules.

27,119. All the passengers were examined?—Yes, they were all examined by English nurses, and then from the examination on the quay they were taken through the Custom-house—where all their things had to be examined by the Customs authorities—into the segregation camps which were all carefully railed off. There were four or five large "dharamsalas,"—stone buildings—and every accommodation was given there for providing food and everything that they wanted.

27,120. Were all passengers segregated, or did you select certain of them for segregation?—They were all segregated.

27,121. For what period of time?—That varied. When the plague was bad they segregated them for 20 days, and later, when it got less virulent, 10 days. It was 10 and 20 days.

27,122. How many people did you deal with in that way?—The segregation camp opened on October 7th, 1897, and closed on the 22nd July 1898, during which time 15,958 passengers passed through; 178 were sent to the observation hospital, and 22 to the Plague Hospital.

27,123. Plague developed in 22?—Yes.

27,124. But 178 had symptoms suggestive of plague?—Yes.

27,125. You say that these 178 were sent to a separate place?—Yes, they were sent to the observation hospital away from the rest to see whether they developed plague or not.

27,126. And 22 of them developed plague?—Yes; cases of illness were sent originally to the observation hospital, and then from there they were drafted into a separate Plague Hospital which was nowhere near the segregation camp.

27,127. Of these 22, how many died, and how many recovered?—19 died, and 3 were discharged.

27,128. Have you had any experience of Haffkine's prophylactic fluid in Cutch?—None at all.

27,129. Did you use the serum from Paris as a prophylactic?—Yes, a certain amount of it was used.

27,130. How many persons were treated with it?—Owing to the objections raised by the Cutchis, serum, as a preventitive, was not used to any considerable extent. 1,044 persons of all ages were inoculated, of

whom five were afterwards attacked with plague. I put in a table showing those who were attacked :—

		Inoculated.	Attacked.	Result.
*(1.) Aisanbar -	Mundra Borah Caste.	14.9.97	26.9.97	Died 28.9.97.
*(2.) Kharmji -		„	„	Died 1.10.97.
(3.) Esmailyi -		„	25.10.27	Recovered
(4.) Isayi -		„	16.10.97	„
(5.) Mahomed -		„	„	„

* Brother and sister both attacked 12 days after inoculation. Their mother was attacked with plague two days after the children were inoculated.

27,131. How many of the plague cases died in which serum had been used as a preventive?—Two died and three recovered.

27,132. In the fatal cases was there any beneficial effect, as far as you could observe, from the injection of the serum? — Not that I could see. The only point was that the brother and sister were both attacked 12 days after the inoculation, and the mother was attacked with plague two days after the children were inoculated. It is quite possible that they may have had plague if they had not been inoculated with this preventitive serum.

27,133. Do you know the interval of time in each of these five cases between the injection of the serum and the occurrence of the plague?—Yes, they were all inoculated on the same day, and the dates are given.

27,134. What dose of serum was given?—Ten c.c.

27,135. One injection?—Yes.

27,136. (*Mr. Hewett.*) Did you find in the first epidemic that many cases of plague occurred in the same house?—Yes.

27,137. I mean when people were left alone in their houses?—In the earlier part of the epidemic there were more cases in one house than there were later.

27,138. Did you find any difficulty in recognizing the disease?—Roughly, I say not.

27,139. Do you think that many cases escaped detection by reason of their not being recognized?—Most of the cases which I saw were brought to me in hospital. Whether cases escaped the search parties I do not know at all. I do not think that many cases which were brought to hospital were missed because they were not plague. One was constantly going to houses to decide whether cases were plague or not, and I should be inclined to think that very few of them were missed, because if there was any doubt about it they were either removed to the observation bospital or to the Plague Hospital.

27,140. (*Prof. Wright.*) Were there many cases which had no buboes which were diagnosed as plague?—Yes, there were a great many.

27,141. Had you any difficulty in differentiating these non-bubonic cases from other diseases?—One had a certain amount of difficulty in some cases. Some of them were easy enough. The pneumonic cases were easy enough, but, of course, one did get a certain number of cases in hospital which were undoubtedly malarial, and then there was a difficulty in differentiating them from plague during the early stages. One had fevers of various kinds brought into hospital, and those, in some cases, were treated by serum and afterwards discovered to be malaria, and then they were eliminated from the list.

27,142. (*Mr. Hewett.*) And any inexperienced medical man might very easily think that cases were plague which were not plague?—Yes, many of the native assistants sent all kinds of cases into hospital which were not plague, and which had to be sent out again.

27,143. In the course of your service with the British troops in India did you come across cases in which soldiers got these buboes?—Yes. I treated two of them in Kolaba Hospital. That was where I got it myself. I got it from one of those men.

27,144. You had plague yourself?—Yes.

27,145. And these men also had plague?—Yes.

27,146. (*Prof. Wright.*) When was the epidemic worst in Cutch Mandvi?—I cannot remember the dates. It was worst when I first went up there in May and June.

27,147. Was it getting better by August?—Yes.

27,148. Your first 100 cases which you took as controls to the serum cases were cases which you took in May?—Yes.

27,149. Would there not have been a greater mortality in May and June, when your control cases came under observation, than in July and August when your serum cases were observed?—Yes.

27,150. If these 100 cases had not been treated with serum would you not expect to get a smaller mortality among them than among the 100 cases which you take as controls?—Yes, but not so small as after the use of the serum. If you like I will send you up 100 cases which we got later on still, and 100 of those which were inoculated later. Perhaps they will be more favourable for the purpose of comparison than those two groups. These were the first 100 cases which were admitted into the hospital.

27,151. Can you give us cases which were not treated with serum which occurred within the same dates as your serum cases?—Yes, that is what I will endeavour to do. (The witness intimated later that the list was not available.)

27,152. Do you know whether it will make much difference in the results? You have not worked that out, have you?—A certain amount of difference, possibly, but not much. The mortality is always heavier at the beginning of the epidemic than at the end.

27,153. Did you take every case and inject it with serum, or did you leave a certain number in the hospital un-injected with serum during those months of June, July, and August?—There were possibly some who objected to be inoculated, but, as far as I remember, all were inoculated. Of course a certain number were bound to be in the hospital which were not treated, because they might have been brought in after four days, or moribund, or brought in for diseases which were not known for certain to be plague. A certain number of that class were bound to be in the hospital.

27,154. How, then, can you furnish control cases which are strictly comparable to these serum cases?—Only by giving, as you suggest, those who were admitted about the same dates.

27,155. Did you get out your serum direct from the Pasteur Institute?—Yes, it came direct from the Pasteur Institute.

27,156. Was it sent to you direct?—Some was sent to me and some of the serum was that which Yersin left when he went away. Yersin come up for a few days and did some experiments, and then he was recalled.

27,157. Do you think you can give such particulars as will suffice to identify the particular serum which was used? We can then inquire at the Pasteur Institute as to how the serum which you employed was prepared?—That is so. (Witness intimated later that no particulars were obtainable.)

27,158. Were a whole series of sera employed for your injection?—Yes.

27,159. Do you know whether they all came from horse No. 31 whose serum you tested on animals (*see* Question No. 27,067)?—Oh no, they came from various horses.

27,160. Then the serum which was employed for your animal experiments was not the only serum which was employed for your therapeutic inoculations on man?—No.

27,161. It was only one of the sera which you employed?—Yes.

27,162. Can you particularise the cases which were treated with this particular serum?—No.

27,163. They were all mixed up?—Yes, as they came out they were used.

27,164. (*The President.*) Have you not a special note on the record of the case indicating what serum it was?—No.

27,165. (*Prof. Wright.*) I notice that in the third series of experiments which you put in you say: "One "mouse was inoculated with material derived from a "human plague pustule"?—Yes.

27,166. Could you tell us in connection with that, what eruptions you have seen in connection with

Capt. H. D. Mason, R.A.M.C.

20 May 1899.

plague? Have you seen a pustule eruption?—No, I mean the plague pustule which starts with a large black blob, and which goes on to necrosis.

27,167. With regard to these carbuncles, do they, in your experience, invariably occur at the very beginning of the plague attack, or do they occur also during the course of the plague attack?—As far as I remember, I have seen them on patients when they were admitted into hospital, on the body at various places, and others where they developed after the patients came into hospital.

27,168. You do not adopt the view that one of these phlyctenules indicates the original site of infection?—No, they are part and parcel of the plague itself.

27,169. Was the synovitis which you speak of ever complicated with urticaria?—No.

27,170. Did synovitis ever occur when you gave as little as 10 c.c. of serum then?—No. I am not at all inclined to say that it was due to the serum at all, except that it was an observation made after big doses in a few cases that this synovitis resulted, and we thought that possibly it was due to those large doses.

27,171. You speak in your précis of pyæmic plague occurring in association with abscesses all over the body: did these abscesses occur in association with buboes?—No; I called to mind one case of necrosis of the scalp—three or four places in the scalp where abscesses developed and left a large necrosis as big as a five-shilling piece.

27,172. Is this not similar to the carbuncle you have spoken of previously?—No.

27,173. It was a different kind of abscess?—Yes.

27,174. Was corpse inspection resorted to in Cutch Mandvi?—Yes. We went to see cases of people who had died to verify whether it was plague or not.

27,175. Was an objection ever made to your inspecting the corpse?—None whatever.

27,176. Were objections not raised among the Muhammadans?—No.

27,177. Have you ever noticed any œdema on the chest of people who died of plague?—Do you mean œdema extending from buboes?

27,178. That is a moot point. I understand that in cases of axillary buboes the œdema may extend right over the front of the chest?—Yes.

27,179. I am inquiring, however, with regard to cases of pneumonic plague and inguinal plague. Œdema of the chest has been asserted to occur in such cases; has that come under your observation?—Never with pneumonic plague, but in many cases of inguinal and axillary bubonic plague.

27,180. Do you think much importance is to be attributed to the œdema as a sign of plague?—No, because so far as my experience goes you get a bul first, and then the œdema extends from the bubo.

27,181. You have not found this œdema in septicæm cases of plague?—No.

27,182. With regard to pneumonic plague have y ever seen complete solidification of the lungs?—I ha had very little experience of *post-mortems*.

27,183. But have you ever seen dulness extendi all over the chest?—As far as I remember there we only a few cases. One side was completely dull and r breath sounds at all.

27,184. Those cases are of very rare occurrence a they not?—Yes, the great majority are of the lobul form.

27,185. Is it difficult to distinguish between t septicæmic form of plague and the pneumonic?—Yes

27,186. Very difficult?—Yes.

27,187. Do you find that nearly every case septicæmic plague is complicated with some pneumon symptoms?—Yes.

27,188. You would not make a special category pneumonic cases of plague, would you?—No.

27,189. You do not see your way to make thes different categories of bubonic plague and septicæmi plague and pneumonic plague?—No, it is all plague.

27,190. (*Mr. Cumine.*) Were there private cas hospitals at Mandvi when you were there?—Yes.

27,191. How did the willingness of the people to b taken to these non-official hospitals compare with the willingness to be taken to the Government hospitals?- Most favourable for the caste hospitals. We had n difficulty in getting them to the caste hospitals, b very considerable difficulty in getting them to th Government hospitals.

27,192. (*The President.*) I want to make one poi clear. Did the synovitis which you observed in plagu cases occur only in those who had received injection of serum?—Oh no: one gets synovitis in cases treate with ordinary methods as well. That is why I mad it a point that it is not certain that it is due to th large doses of serum. But it was curious that o found synovitis when large doses were given, and on also found it when there was no serum given.

27,193. Can you go so far as to say that the synoviti was more frequently seen in those cases where yo gave large doses of serum?—I cannot say that.

27,194. It might be a coincidence?—Yes. Whethe it was due to the serum or not I am not prepared t say.

27,195. In the cases treated with serum in whic synovitis appeared, did the synovitis appear only whe large doses were given, or also with small doses?—A far as I remember, only where large doses were given

(Witness withdrew.)

Major R. W. S. Lyons, I.M.S. called and examined.

27,196. (*The President.*) Are you in the Indian Medical Service?—Yes.

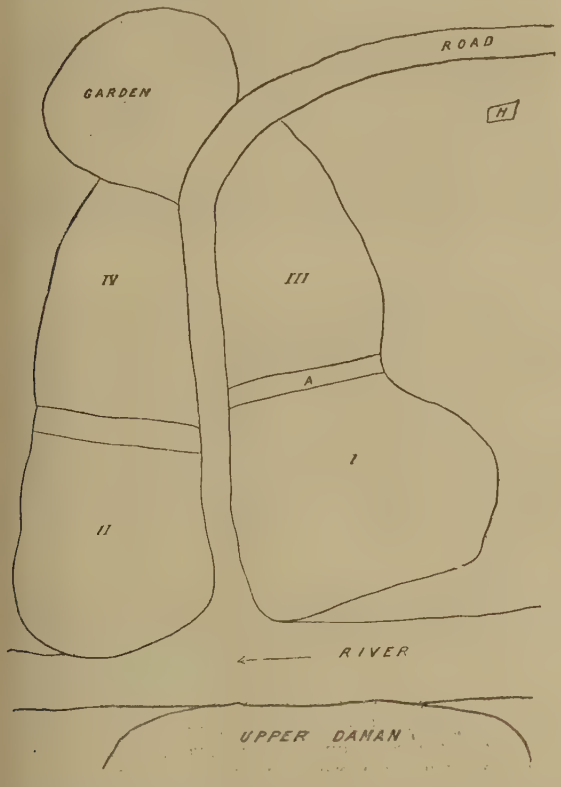
27,197. What are your medical qualifications?—I am M.D. of Queen's University, Ireland.

27,198. (*Mr. Cumine.*) Did you go to Daman?—Yes.

27,199. To inquire into inoculations there?—Yes.

27,200. Will you tell us how you conducted the inquiry?—Yes.

27,201. Did you go to every house in the town?—Perhaps I had better begin at the beginning. You have been to Daman, and you know that it is an ordinary native town with one large street down the centre, and a cross street dividing it, somewhat unequally into four parts. The road to Daman curves round in this way—



I started by taking *this* (I) section. With a few exceptions, the people are very poor and live in small houses, generally of one room each. Sometimes there is a room behind the front room, and running along the front is a verandah. I went to the first house and inquired if there were any inoculated people there, and, if so, had any attacks of plague occurred among the members of the family. They told me whether there had or not, and then, if attacks had occurred, I found out whether they had occurred before or after the inoculation, and whether among the inoculated or uninoculated. Then I inquired if they knew if there were any inoculated in the next or adjoining houses. I did this at each house, so as to make as certain as possible that I did not allow any to escape me. I went through each section of the town in this way. *These* streets divided them very fairly. *This* (IV.) is the smallest division, because this garden contained a large number of people whom I could get hold of at the same time. They were people employed in the garden, and who lived in little huts all around, as gardeners do in India. *This* (IV.) was my last day's work. I finished early and went to some shelter evacuation huts which had been put up in the fields about *here* (H), not far from the road.

27,202. Did you go to every house in the town?—So far as I am aware I visited every house in the town, with the exception of that in which Dr. Fernandez, the man who assisted me, lived. I got information from a person in each house as to what the results were there. They might have deceived me if they wished to do so, but they had no reason to, and Dr. Fernandez had no reason to deceive me with regard to his own house.

27,203. What I wished to get clear was the extent to which you went to all the houses. You say you went to every house in the town?—Yes.

27,204. Not merely to those houses in which, there being both inoculated and uninoculated persons, you were informed that an inoculated or an uninoculated person had been attacked with plague?—No. My first inquiry was: had any inoculations been done in the house?

27,205. (*Prof. Wright.*) Does that refer to Upper Daman or to Lower Daman?—Lower Daman.

27,206. Is Upper Daman part and parcel of the same town?—No. It is separated by the river from Lower Daman. Upper Daman is quite a small place, composed of a fort, with a small number of houses outside the fort.

27,207. Were any inoculations done in Upper Daman?—I do not know. Our inoculations were done only in Lower Daman. When they were started the Governor had placed a cordon along the river to cut off all communication between Upper Daman and Lower Daman.

27,208. There were no inoculations in Upper Daman?—I cannot say. We sent the Governor a certain amount of serum for inoculation; but whether any were done or not in Upper Daman we were not informed.

27,209. Is the population of Upper Daman included in your estimate of the population?—No, it is excluded.

27,210. (*Mr. Cumine.*) Did you make out investigation sheets?—Yes.

27,211. Did you bring into these investigation sheets all the houses in which inoculated people lived?—No, only those families in which plague cases had occurred, and in which inoculations had been done. *This* particular street (A) had the worst outbreak of plague of any that I found. In *this* street there were two or three houses, in each of which all the inhabitants had been inoculated; and all had escaped plague entirely. They were the only houses in the street which escaped plague entirely. It was a most convincing example of the benefit of inoculation to anyone who saw the surrounding circumstances; but this cannot very well put it on paper statistically.

27,212. To what extent did you see other inoculated persons who are not brought into your investigation sheets, and to what extent did you find out, by actual investigation, what had happened to them?—I merely inquired at each house if plague cases had occurred. I did not examine each individual who was inoculated.

27,213. When we see in your investigation sheets that in a certain house in Daman three inoculated persons were living, and that one had plague and recovered, are we to understand that you made these entries because you saw these three persons in the house, and actually saw the person alleged to have recovered, or merely that you were told that these people were living there, and that one had had plague and recovered?—In each house I obtained from one person, who was fairly intelligent, all the information.

27,214. (*Prof. Wright.*) How was the population arrived at?—That was a difficulty, as there was no census. The population was obtained from the Governor. The Governor told us there were 12,000 people, as far as my memory goes, in Lower Daman. (Note by witness on correcting proof of his evidence:—This statement is wrong. The Governor told me that the population of Daman was about 11,000, not 12,000.)

27,215. I think you put it down at 10,900?—Yes; we took the liberty of cutting it down. (Note by witness on correcting proof of his evidence:—We believed that the population of the town was reduced by 1,000 deaths at least, from plague, during the month of February.)

27,216. But that improves your statistics?—No, it brings them down.

27,217. The larger the population the smaller is your percentage of mortality?—On the total population, yes.

27,218. So that, if you cut down the population from 12,000 to 10,000, you improve the statistics, since your uninoculated population is got by subtracting your inoculated population from your total population?—We cut off 1,100. I think, if you had gone through Daman,

Major R. W. S. Lyons, I.M.S.

20 May 1899.

would have thought that we estimated the population fairly correctly.

27,219. I am not calling that in question, but we want to get at the exact facts. I want to know how the population was arrived at. Your statement as to the number of the inhabitants is worth more to me than the Governor's if you tell us how you arrived at your estimate?—I personally thought, and Mr. Sorabjee Damaun Wallah, who knows Daman, ultimately also thought, that 12,000 was too high.

27,220. I have an intimate knowledge of certain towns, and yet I have no idea as to what is the exact population of those towns?—That was our difficulty in this case. There is no census.

27,221. I want to know how these figures, which you put in, were arrived at?—There was no census so far as I am aware. I tried to get a census.

27,222. What did you substitute for a census?—We substituted that 10,900.

27,223. How did you arrive at that figure?—We arrived at it partly from the Governor's statement, which was 12,000 (*see* note by witness to Question No. 27,214 above) and from the estimate of Mr. Damaun Wallah, which was 11,000. (Note by witness on correcting proof of his evidence:—This statement is wrong. Mr. Damaun Wallah estimated the population at about 10,000.)

27,224. You have estimated it at a little less than either?—Yes.

27,225. What principle did you take as your guide in cutting the population down?—None.

27,226. Is then your estimate of the population anything more than a guess?—It was quite a guess.

27,227. Then what is the meaning of your working out your percentages to the decimal point?—I think there is. One must take some standard to go by, one must have a standard whether right or wrong, and even if one argues out statistics from a false standard one gets an impression not exactly right, but one does get an impression in which there is an uniform error all through.

27,228. But it may be evenly wrong in favour of the inoculations as well as against them. Your statistics are worked out here to decimal places?—With regard to the inoculations, as far as I know, the results are absolutely correct.

27,229. But, first I want to get the facts about the population. You say 10,900 is the population. That is got at by guess?—That is so.

27,230. Then you subtract from this number 670 persons who you say died of plague before that time, how did you get at that figure?—I do not remember the figures now, it is two years since I worked them out.

27,231. As far as I understand from your printed report,* the Governor told you that the death-rate might be reckoned as averaging 30 a day?—Yes.

27,232. Further, the Governor told you that you might neglect all deaths before the 1st March?—We did.

27,233. The plague began on the 1st February, but, the Governor told you, you might neglect the deaths in February, and that you might estimate the deaths in March as averaging 30 a day?—Yes.

27,234. But when I take that estimate, and when I multiply by the number of days up to the 24th March, when the inoculation were begun, I make the deaths to be 720. You, on the other hand, arrive at the figures 670?—We lowered the estimate of the death rate to 26 a day, because Mr. Damaun Wallah——

27,235. Who is the Damaun Wallah?—He is the owner of about three-fourths of Lower Daman. He made a census of the families in which deaths occured, which gave the total number of deaths at 2,352.

27,236. Do you know how he made the census?—I believe he made it by collecting from house to house the reports of all the deaths.

27,237. We have it that the people emigrated in large numbers, were there not lots of quite empty houses in Daman?—Yes.

27,238. How then could the Damaun Wallah get at the correct number of deaths?—After the emigration had occurred, he could not obtain statistics. He made his census after the plague cordon was removed and when the people had come back to their houses, when there were no deaths in Daman, in fact, while it was plague-free, and the towns around were infected, so that he would probably have the greater number of his people back again. But, in any case, taking into consideration the fact that he may have made mistakes, he reduced the average to 26 deaths a day instead of 30 a day, that we estimated it at.

27,239. Then, you say 2,000 people left the place, was that a guess too?—Yes, although it is a pretty accurate guess, for the reason that it was so estimated by Mr. Judge, the Salt Commissioner, who was on the frontier, and who knew about the number of people who passed out each day.

27,240. He did not draw his cordon round Daman till later, did he?—Yes, there was always a salt cordon. The cordon was not closed with regard to people until he settled down there himself on a certain day.

27,241. Do you know how this estimate of 2,000 emigrants is arrived at? You say Mr. Judge knew. Did he give the information to the Governor or did the Governor guess?—As far as I remember I had the number from Mr. Judge, not from the Governor.

27,242. Did the people emigrate by sea as well as by land?—Almost all by land. I should think all by land, because with the exception of the fishing population they have no boats, and they could not get into Bombay or any harbour along the coast, coming from a plague-infected place.

27,243. Do you know anything about the strength of the vaccine which was employed at Daman?—No.

27,244. Was the strength of the vaccine experimentally tested?—I do not know, I am not a bacteriologist.

27,245. Are you able, in your statistics, to separate the persons who were vaccinated in the first series of inoculations from those in the second and third series? When you say that 1,372 persons were inoculated and that the mortality among them was 13 per cent., is it not true that these 1,372 are made up of two different lots, *i.e.*, of some who had been inoculated a month before, and of some two months before?—Quite so.

27,246. We have no data given here to enable us to determine whether the effect of the inoculation was less in the second month as compared with what it was in the first?—That is a thing which I would like to have done, but I will show you the difficulty. If you take any inoculation sheet you will see that some of the members of the family were inoculated once and some twice. If they had all only been inoculated once we could have followed out each series inoculated from beginning to end separately, that is to say, taking the total number inoculated on the first occasion we could have followed out their statistics separately and kept them apart from the number inoculated in the second series of inoculations. But a number were inoculated both times, both first and second. Supposing, in a house, every one wished to be inoculated, they would not want to have it done at the same time, because the inoculated were laid up for some days, and there would have been no one to cook or do the housework. Therefore, a certain number were inoculated, say this month, and next month some of the first series were in many instances inoculated again, and the remaining members of the family were inoculated for the first time.

27,247. With regard to these inoculations you say that Dr. So-and-so did so many on a particular date; I do not know whether the figures which are given refer to new people, or whether they include also second inoculations?—All the inoculations so referred to in these statistics are first inoculations.

27,248. And you have no reference as to second inoculations?—Oh, yes.

27,249. You have not put it into this statement?—No, you will find it in these sheets.*

27,250. But you have no statistical summing-up of the results attained by second inoculation?—No.

27,251. Then these results apply sometimes to people inoculated once and sometimes twice?—Yes.

27,252. Your report shows the effect of single, and in some cases of double, inoculations for a period of six weeks after inoculation?—Yes.

* *See* App. No. II. in Vol. I. of these Proceedings.

27,253. You did not make any subsequent inquiry as to the fate of these people?—Daman was plague-free in June 1897, when this report* was drawn up and remained plague-free till I left in November. This investigation was made up to the 1st June, I think. Of course, I do not know what was done after I left India.

27,254. You say in your report that, although you have not determined the duration of immunity, the facts you have collected show that the question has lost its urgent interest. What is the meaning of that?—My idea is, that if a way has been found of preventing plague from spreading, that is all that is required.

27,255. But in the case of Bombay, where you have plague lasting for a long time, do you think that an immunity, which lasted for six weeks and no longer than six weeks, would be of any avail?—We do not know that protection lasts only for six weeks, but even so, why should they not get re-inoculated every six weeks when plague is prevalent around them?

27,256. Cannot you give us any data with regard so the duration of the immunity?—No. That could have been done at Tarapur. I inoculated about 600 people there myself in 1897, and they had a second outbreak at Tarapur in the following year.

27,257. You say a weaker vaccine was used for the second and third inoculations, and you say that, in consequence of this, much larger doses were given?—Yes. It did not give as favourable results as the more powerful inoculation.

27,258. It did not give as great a clinical reaction?—That is so.

27,259. Do you know why the dose was not increased until it did give as satisfactory a clinical reaction as the first and stronger vaccine?—Yes, I do partly. The inoculations were being performed by native doctors, and we did not trust them to investigate the clinical effect of increased doses.

27,260. I do not quite see the bearing of that. Do you mean you would not take their word that the reaction which was obtained was slighter?—No, we did not trust them to increase the doses. I know from the inoculations I did myself that the reactions were not equal.

27,261. But, if you had known that at the time, you would, would you not, have increased the dose?—I did afterwards, but I never got the same re-action.

27,262. Why did you not increase until you got the reaction you desired?—I was not sufficiently acquainted with the action of these toxines to do that.

27,263. I understand that at first the standard dose of 2½ c.c. was given?—Yes.

27,264. In the second and third inoculations you gave two or three times as much?—Three, four, five, or six times as much.

27,265. That is, you gave 12½ c.c.?—Yes, more than that. I have given 15 c.c.

27,266. You did not give 30 c.c. because you thought there might be risk?—Yes.

27,267. Did you take the temperatures of these people when you inoculated them?—Yes, I took a certain number. With the weaker serum, frequently, I did not get a temperature more than 99°, rarely over 100°, whereas with the stronger serum one got a temperature rarely under 101°.

27,268. I do not see specified here what inoculations you did—the second, third, and fourth series?—I never did any of those inoculations at Damaun.

27,269. Then you inoculated elsewhere with some of this same vaccine?—Yes, I did, in Bombay and on Europeans, where I had every chance of knowing exactly how the temperature was ranging.

27,270. Had you any opportunity of finding whether the Europeans you inoculated there did receive benefit from it?—No cases of plague occurred among them. Europeans seemed to be very little subject to plague in Bombay.

27,271. Have you any notion what the limits of error are in the estimates of population which are arrived at by guesses?—No.

27,272. We have had in evidence different estimates of the uninoculated population of Hubli, and these estimates varied between 500 and 8,000. Do you think that your estimates of population may be as wrong as some of these?—I would have a very poor opinion of the intelligence of a witness who could not distinguish between 500 and 8,000 persons.

27,273. You do not think there may be errors of this order of magnitude in your statistics?—No.

27,274. How many houses did you visit?—I have no idea. Purely as a guess, I should think I visited between 500 and 600 houses.

27,275. What would the population of those houses be?—I cannot tell you that.

27,276. You, practically, made a census of the town if you went round to every house?—That is not so easy as you appear to think. If one inquires at a house whether inoculations have been done there, and they say "No," one goes on to the next house at once. If one had to write down the name of every individual in the house, their ages, and so forth, one would spend a quarter of an hour, or half an hour, according to the number of people there.

27,277. You could average the number of inhabitants in the houses?—You will see by the sheets that they varied enormously.

27,278. I say you could strike an average?—Some were 21, and some four, and so on. If one rejected the highest and the lowest number, and struck a mean for the remainder, one could have got an average; but I was not looking for that.

27,279. You cannot supply us, can you, with the number of houses which you visited, so as to enable us to construct some sort of census by multiplying the number of houses by the average number of inhabitants as shown in your investigation sheets?—No.

27,280. (*Mr. Cumine.*) Can you tell us, from this Report* (*handed to witness*), the percentage mortality during the time they were under observation, amongst the total uninoculated and the total inoculated, separately?—24·6 per cent. for the uninoculated, and 1·6 for the inoculated.

27,281. Can you tell us what is the mortality of the uninoculated and the inoculated in your investigation sheets?—For the uninoculated it was 43·5 per cent., and 20 per cent. for the inoculated.

27,282. That is the percentage of attacks; will you mention the percentage of deaths?—29·8 per cent. deaths in the uninoculated, and 8 per cent. in the inoculated.

27,283. The mortality rate among the inoculated in your investigation sheets would be some five or six times higher than that among all the inoculated? It is 8 per cent. among the people in your investigation sheets, and only 1·6 per cent. among the total inoculated; so it is five or six times higher among the former, is it not?—Yes.

27,284. Therefore, it becomes important to see to what extent you ascertained what had happened to the inoculated people who did not come into your investigation. Were there a certain number of inoculated people not in your investigation sheets about whom you did not manage to find out anything at all, whether they were alive or dead?—No, I inquired at each house if inoculations had been done, and whether cases of plague had occurred.

27,285. At some of the houses to which you refer, were you unable to get any information about a certain number of the inoculated people?—No; I asked whether any cases of plague had occurred, and if no plague cases occurred I did not inquire further.

27,286. How did you know whether any plague cases and occurred or not?—I had to depend on the statement of the people in the house. There is a reason, of course, why the death-rate should be higher in the 84 houses to which these sheets refer, because they were plague infected. Where a case of plague occurs in a house it is generally found that plague spreads right through the house; where a case of plague has not occurred the house may escape scot-free, although plague is all round it.

27,287. (*Prof. Wright.*) Cannot you also test your results in another way? What is the relative mortality of the inoculated and the uninoculated as recorded in your investigation sheets, and how does this compare with the relative mortality among inoculated and uninoculated in the general population?—Are you referring to the inoculated and uninoculated as a whole,

* *See* App. No. II. in Vol. I. of these Proceedings.

Major R. W. S. Lyons, I.M.S.

20 May 1899.

or those in the houses where plague cases have occurred, or where inoculations were done?

27,288. I understand that the mortality from plague will be greatest both among the inoculated and among the uninoculated when there is a case of plague in the house?—Yes.

27,289. And the inoculated and uninoculated alike will have a better chance of escaping plague if there are no cases of plague in the house where they are living?—Yes.

27,290. Therefore, let us determine the number of the plague deaths among the inoculated and uninoculated in the plague houses, and let us compare that with the number of deaths among inoculated and uninoculated who were not living in plague houses. Can you supply me with these figures? You have stated in your tables that there was a death-rate of 8 per cent. among the inoculated; what was the death-rate among the uninoculated in these houses which you have tabulated?—29·8 per cent.

27,291. That is practically 30 per cent. The percentage among the inoculated for the whole town was 1·6 per cent; what was the percentage of the uninoculated for the whole population?—24·6 per cent.

27,292. Then the relation of the mortality of inoculated to the mortality of uninoculated in plague houses is 1 to 4, while the same relation all over the town was 1 to 15. These figures are, surely, not comparable?—I think you will see that 24·6 per cent. is the death-rate among the general uninoculated, which is lower than 30 per cent. among the uninoculated occurring in plague-stricken houses.

27,293. I am quite prepared to take that, but these cases of death among the inoculated which appear in your investigation sheet were brought to your knowledge by the fact that you made a census of the houses. But the cases of death among the inoculated in the town outside were not brought to your knowledge in the same accurate manner?—You must remember there are a great number of persons in the town who never come in contact with plague.

27,294. That applies to the inoculated as well as the uninoculated?—Quite so.

27,295. I take it that these investigation sheets are correct, and this being so, they ought to be a picture in small of what occurred in the whole of the town, ought they not?—Yes.

27,296. We find that they are not a picture in small of what occurred in the whole town?—I think I can show you the reason. In the plague-infected houses almost every person catches plague, in the town every person does not catch plague. The reason probably is that a great number of the inhabitants of the town have not come in contact with plague.

27,297. I do not see that this meets the point?—In order to get comparative statistics for the whole town I should have taken in a street say, four houses, in which inoculations had been done and compare them with four on the opposite side of the street in which, perhaps, every member had been attacked by plague, but I did not do this. I neglected those inoculated houses altogether in which plague did not occur. My object in selecting only plague-stricken houses in which inoculations had been done was not to find evidence in favour of inoculation, but all the evidence there was against it. I did the same in Bombay; I investigated every plague case among the inoculated there, and advertised for them in order to obtain all the evidence against inoculation.

27,298. I have had experience of the futility of the effect of advertising for information?—In Bombay I had particular advantages. I knew the majority of the medical practitioners, and anyone who was called in to a case of plague in which inoculation had been done always told me about it.

27,299. (*Mr. Cumine.*) There are four investigation sheets?—Yes.

27,300. Will you look at that Report* ?—I have the Report here. There are four sheets.

27,301. When the proof of your evidence is sent to you for correction will you put down with regard to each of these four tables separately the attacks and deaths amongst the inoculated and uninoculated respectively?—May I explain what these sheets are? In the first division all the families are shown in which inoculations were done on the first occasion in Daman. Through a printer's error two families which should have appeared in the first division are shown in the second. In this first series there are a considerable number of inoculations done on the second occasion—not the majority, but a certain number. In the second series there are no inoculations done on the first occasion, they are all inoculations done on the second occasion. In the third series they are inoculations done on the third, and in the fourth series on the fourth occasion, after the plague had stopped in Daman altogether, for a number of people were inoculated even after the plague ceased.

27,302. Do you think that any inoculated people could have emigrated? Were there any privileges given to inoculated persons?—Not from Daman.

27,303. (*Mr. Hewett.*) They could have emigrated, I suppose?—No, I do not think so.

27,304. Why not?—Mr. Judge kept a strict look out.

27,305. Do you think that a cordon can keep people in a place?—I do not think it can keep individuals in a place. But I do not believe that families escaped, although individuals may have done so.

27,306. (*Prof. Wright.*) Do you think that the inoculated in your investigation sheets are comparable, in the matter of age and health, with the uninoculated; or do you think that you have a greater number of the feeble and old people among the uninoculated?—If you look through these sheets you will see exactly. I have put down their ages in each case.

27,307. I only wanted to know whether, when you saw these people, you thought the uninoculated were comparable as a whole with the inoculated people. You probably saw them?—Yes.

27,308. Why were these people not all inoculated?—It not unfrequently happened that, when the members of a family went to be inoculated, one or more were left at home to attend to household matters.

27,309. (*The President.*) Why did they not go?—It is on account of family life in India.

27,310. (*Mr. Hewett.*) I think you did over 8,000 inoculations in Bombay City?—No, I did not do them. I did a certain number there. I think there were about 18, or perhaps 20, cases of plague which occurred among the inoculated in Bombay, and I found out from the people who treated them all about these.

27,311. You say that these 20 cases occurred; how do you gather that other cases did not occur?—That I cannot be sure of.

27,312. So that the facts would not bear so much upon the relative immunity of the inoculated?—Not on the relative immunity of the inoculated; but it did show a result which Daman did not show.

27,313. What was that?—In the 18 or 20, as far as I remember, there was no death.

27,314. At what period of the epidemic was that?—I came to Bombay on the 25th of January, and the plague was at its height in Bombay about the end of March or the beginning of April 1897. They occurred during that time.

27,315. Have you any security that the practitioners always gave you the cases which were unfavourable to inoculation?—They knew that I was looking for them. Of course, I have no guarantee.

27,316. These were native practitioners, were they not?—Yes.

27,317. Assuming that benefits were given to the inoculated persons, it would be to their advantage to let you see that the results of the inoculations were good?—There was no benefit to be given to inoculated persons.

27,318. There was subsequently, and there was some idea that there might eventually be?—My impression is—it is merely an impression—that the very opposite was the case—that the native practitioners sought out every possible thing they could against inoculation.

(Witness withdrew.)

* *See* App. II. to Vol. I. of these Proceedings.

Dr. KLEIN, F.R.S., called and examined.

27,319. (*The President.*) You have been for years employed by the Local Government Board in biological research?—Yes.

27,320. (*Prof. Wright.*) Perhaps you will begin by telling us something of the morphological characteristics of the plague bacillus. I see* you lay great stress upon the fact that certain of the colonies which are produced on agar are thready colonies?—That was in gelatine plates.

27,321. Your experience was gained, was it not, by a study of two different cultures of plague?—Yes.

27,322. One of them was obtained from a plague case which occurred in London?—Yes, and one was sent from Hong Kong.

27,323. Have you verified that your observation holds true also in other plague cultures?—I have not had any others.

27,324. I do not think that in your Report to the Local Government Board you referred to the formation of stalactites in broth?—No.

27,325. Have you confirmed M. Haffkine's statement that a stalactitic growth is invariably obtained with cultures of plague?—I have not worked on the same lines. Owing to the Vienna scare, we were put in a very awkward position.

27,326. Have you verified Mr. S. Mervyn Gordon's statement that the plague bacillus possesses flagella?—Yes, but very few bacilli have a flagellum.

27,327. You do not lay any stress in your Report to the Local Government Board upon involution forms; do you think these involution forms are very common in cultures and very characteristic?—They are very common where the media is not absolutely suitable; for instance, in Hankin's cultures where there is an excess of salt.

27,328. Have you found that to be a good medium upon which to obtain involution forms?—Yes, but I have not had a sufficient number of human cases to make a series of observations upon. In those I have had before me there were no involution forms in the active cultures.

27,329. Do you know whether your cultures still give involution forms or not, or whether they have ceased to do so?—I have not tried that.

27,330. Do you know whether bipolar staining can be got in bacteria grown on artificial media?—Yes, constantly.

27,331. I ask because there is an impression that bipolar staining can only be obtained in the case of bacilli which are obtained directly from the animal?—No; I think bipolar staining is a very characteristic feature.

27,332. It is said that when the plague bacillus is transferred from agar to agar for a number of generations it no longer shows bipolar staining?—I doubt that. With regard to these bipolar stainings, it depends so much on the operator himself as to the way it is stained and the way it is washed afterwards. You can get from the same culture preparations which show these bipolar stainings, and in others slightly different you would not have it.

27,333. We had it in evidence that bipolar bacteria are often found in the earth; do you think that the fact that these bacteria showed bipolar staining would, by itself, justify the diagnosis of plague?—I should be very slow to do that.

27,334. Do you think that the clear space in the centre corresponds to a vacuole?—I think that it is due to the segregation of their protoplasm, and to the collection of this at the ends of the rod.

27,335. Could you see a clear space in the unstained bacillus?—I must say I have not done so.

27,336. You say the plague bacilli find their way into the intestines of guinea-pigs inoculatod with plague?—Yes; we have made several experiments on that point with animals dying from plague after inoculation. In some instances the small intestine was found distended with some mucous matter, and we have made not only cultures successfully from it, but in several instances injecting a guinea-pig from this we produced definite plague.

27,337. Have you ever found that the plague bacillus escapes in the fæces?—We have not looked for it there. Only in the animals which died we took out matter from the intestinal canal.

27,338. Have found many plague bacilli in the intestinal canal? Were they in sufficient quantities to be seen under the microscope?—There are a great many other bacteria; but the best and easiest way of showing that they are the plague bacilli is to inject a little of the mucus into the subcutaneous tissue of a fresh guinea-pig.

27,339. Have you ever isolated plague from contaminated matter of that kind; is it easy to do so?—I think that when sufficient care is used there is no difficulty.

27,340. You found bacteria in the bronchial secretions of the guinea-pig?—Yes.

27,341. Did you find them in any of the guinea-pigs before they died of plague?—Only after death. Even in those cases in which guinea-pigs were dying within 48 or 72 hours, and were showing very little change in the lung, except a slight congestion—even in those cases—and those are the cases which are particularly referred to in my Report*—did the mucus in the trachea and the larynx yield cultures of the plague bacillus; where the lungs were greatly involved (inflamed) it is easy to demonstrate the plague bacilli in the bronchial contents.

27,342. You surmised, from your observations on guinea-pigs, that plague bacilli might be found in the human sputum?—Yes.

27,343. I understand that no example of a transference of plague from one animal to another came under your observation?—No.

27,344. Did you take any great precautions to prevent such a spread?—The usual precautions were taken. There is a room with hutches one above the other, in which the animals are placed.

27,345. Have you left infected animals in contact with non-infected animals?—Sometimes there are animals which are infected with material which proves to be non-virulent, and they are put together with animals which have been infected with material which proves virulent. When I say "non-virulent" I mean a material which I have tested and found to be non-virulent. The animals are put together, and the one with the virulent material dies, and the other does not become affected at all with plague.

27,346. But you have not kept quite normal animals in contact with plague-infected animals?—They are in those hutches above and below in the same room. There are animals which we call fresh animals which have not been touched, and we never had any of these becoming infected with plague.

27,347. Have you ever demonstrated the presence of agglutinins in case of plague in animals?—No.

27,348. Have you seen agglutinins developed in men?—No; I have never studied a case of plague in man.

27,349. Have you tested any of the sera sent out from the Pasteur Institute?—I have not seen any. I have myself had sera from guinea-pigs and rabbits.

27,350. Have you ever noticed that animals which received serum which had been drawn off from an animal which had previously been inoculated died faster than control animals? You refer to a case here, in page 296, of your Local Government Report,* Guinea-pigs Nos. 24 and 26. You say, "The result was "rather unexpected, inasmuch as both guinea-pigs "developed the typical disease. The serum-plus-"plague-guinea-pig No. 26 was indeed more severely "affected than the control animal; it died in 24 hours, "whereas the control animal died in 60 hours." You give an instance there of an animal in which the course of plague was apparently hastened by the introduction of a therapeutic serum obtained from an animal which you had endeavoured to protect?—Yes.

27,351. Have you seen such a result from the introduction of other ostensibly therapeutic sera?—I am sorry to say I know of cases where it does occur. There is on organism which I have worked with for the last three or four years, which is present in the intestine of acute diarrhœa, in fact, in all diarrhœa affections you find this organism abundantly present. It is an

* *See* App. B. No. 7 to the Supplement to the Report of the Local Government Board for 1896-7 containing the Report of the Medical Officer.

Dr. Klein, F.R.S.
20 May 1899.

anærobe and is spore-forming; we call it the bacillus enteritidis sporogenes. It is found in sewage, in street-dust contaminated with horse dung, and in human fæcal matter. Some of it is derived from a diseased alimentary canal. If a small part of such material is put into milk and the milk heated to 80° C., so as to destroy everything else but the spores themselves, it yields on anærobic incubation at 37° C. in 24 hours a pure culture of bacillus enteritidis sporogenes. This culture when injected into guinea-pigs invariably produced a fatal result within 20 hours. We can tone down the amount injected into the guinea-pigs so as not to produce a fatal result. The animal becomes ill, has a tumour at the seat of inoculation, the tumour ulcerates, and the animal ultimately recovers. We have had a series of animals and tried to protect them by sub-fatal doses, but we always found that they became much more susceptible to a second infection when they have once passed through the disease.

27,352. Have you inoculated animals with this micro-organism, and have you tested the effect of these animals' sera upon other animals?—Yes, we have done that also.

27,353. And you also found that you got prejudicial results?—Yes.

27,354. So that you think it is possible that the "anti-plague" serum might do harm as well as good?—I should not like to say that, because I should not like to generalize from one instance.

27,355. With regard to vaccination against plague, you have done some experiments—you have inoculated animals by living cultures?—Yes.

27,356. And you find that they do not thereby become noticeably less susceptible to plague?—Slightly less susceptible; after several inoculations with sub-fatal doses they still re-acted. They still re-acted on a fresh inoculation by showing the characteristic tumour and becoming ill.

27,357. Do you know how long this partial immunity lasts?—No, but there is only very slight immunity conferred after several inoculations; the animals are still susceptible.

27,358. Do you find you get better results by using living cultures than by using dead cultures?—I made a large number of experiments with both, particularly with sterilized cultures, and the sterilized cultures certainly have not given those results which one might have expected from similar experiments with other microbes, *e.g.*, typhoid and cholera.

27,359. How did you sterilize those cultures?—By heat—60° to 70° C. for five minutes, 60° to 63° for ten minutes is quite sufficient, but in order to make sure we generally used 62° to 65° for ten minutes or 70° C. for ten minutes.

27,360. Have you determined whether there is a diffusible toxine produced by the plague bacillus?—No, I have not.

27,361. Have you found that the dead bacteria are very toxic?—Apparently not. Large doses injected subcutaneously or intraperitoneally produced no disease.

27,362. You did not get a necrosis of the skin afterwards?—No.

27,363. In the case of animals which have been partially protected against plague, are the *post-mortem* appearances which are found when they succumb to plague in any way different from the *post-mortem* appearances which are found in animals which die rapidly from plague without offering any resistance?—Apparently not; when they die they have the same kind of lesions, that is to say, the spleen is enlarged and full of bacilli, the lung may be affected, and may have necrotic patches; the inguinal tumour at the seat of inoculation shows exactly the same characteristics. I mention here one experiment where an animal, after the fourth inoculation, developed a tumour which suppurated and which contained a great many other organisms besides the plague bacilli, so that these animals do not seem to have offered the same symptoms as an animal which is inoculated for the first time. On page 295 of my Report, I say:—"On the "9th day, the general condition of the animal remain-"ing normal, the tumour, which was still very large, "was examined, and found to be filled with fluctuating "contents: the skin above it, however, was unbroken." The animal had evidently some immunity conferred upon it.

27,364. Have you any experiments to show whether animals can be infected with plague by putting plague bacilli on their mucous membranes?—No, I have not.

27,365. (*The President.*) Have you ever fed animals with virus?—I do not think we have done any systematic experiments in that direction.

27,366. You have nothing to show whether the admission of the virus into the intestinal canal is followed by plague symptoms or not?—No; I could not say anything about that. The only thing I mention here is that animals have died from plague, having the proper bacilli in their alimentary canals. I have not made any systematic experiments by feeding fresh animals with these contents, only by inoculating animals.

27,367. In the alimentary canal were they restricted to the small intestine?—Yes.

27,368. Not in the stomach or higher up?—No. The small intestine was congested and generally distended by mucus.

27,369. These were cases in which the virus had been introduced by the skin?—Yes.

27,370. You think the serum of animals which have recovered from plague is destitute of any immunizing quality?—The serum of guinea-pigs which have been repeatedly infected with sub-fatal doses has certainly very little protective power with other guinea-pigs; that is all I can say. I could not go one step further. After these experiments, which I made on these guinea-pigs myself, I should be the last person to apply them to the human subject. I should like to state that very emphatically. Whatever is to be applied to the human subject has to be found out in the human subject. Whatever I found out on the guinea-pig applies to the guinea-pig. I should like to say that it applied to the guinea-pig only.

27,371. Have you tested the bactericidal power of the serum obtained from an animal which has recovered?—I have made several experiments, but the result was practically nil. One-tenth of $\frac{1}{4}$ c.c. of the serum of an animal which had been injected several times previously with plague culture, and which has recovered from these repeated injections, has very little protective power or germicidal power for another animal.

27,372. Have you made any experiments upon the anti-toxine as distinguished from the bactericidal power?—No, I have not.

27,373. I think I heard you say a moment ago that animals may have had even four attacks of plague and yet are still susceptible to fresh inoculation?—Yes, they re-act; that is to say, they show the tumour, the bacilli develop there, and the animals become ill generally. In fact, if you use a sufficiently large dose they may succumb.

27,374. That is a condition which applies to all immunizations, is it not?—Yes.

27,375. There is no such thing as complete immunity?—No.

27,376. Are the doses necessary to produce the initial re-action required to be increased in order to produce the same re-action subsequently?—Yes.

27,377. Have you made any experiments as to the influence of various external conditions upon the vitality of the bacillus?—Only heat, no other.

27,378. What are the results of your experiments on the effects of temperature?—The temperature, I think, was 62°—upwards of 62° for five minutes—but to make quite sure we heated up to 65° or 70°.

27,379. Sixty-two degrees is sufficient to kill the bacilli?—Yes, 62° or 63° C. for 5–10 minutes.

27,380. Have you made any experiments on the influence of sunlight on the vitality of the bacillus?—No.

27,381. Or of access of air?—I have made recently some experiments—and they will be published in the next Blue Book of the Local Government Board—with reference to the vitality of the plague bacilli in the dead body.

27,382. Can you give us some of the results of these experiments?—Yes. At 14 days they are still recoverable. I am giving you now the results which are still in the printer's hands. I should say that 17 or 19 days

was the extreme length in the guinea-pig. I am speaking of the guinea-pig. That is to say, I inoculate the guinea-pigs with living plague culture subcutaneously, and the animals die between 48 and 72 hours. One set of animals are put in a wooden coffin and another set in a tin coffin, and a third are buried in the earth wrapped up in cloth, and another set are wrapped up in cloth and buried direct in the sand. The coffins are also put in the earth. Then they are exhumed after a given time. After 14 days and 17 days the plague bacilli are still recoverable both from the subcutaneous tumour and the spleen, but after 21 days there are no more living plague bacilli to be recovered from the dead body. Speaking from memory, I am not quite sure that 21 days is not the limit, but certainly beyond 21 days they cannot be recovered. (Note by witness on correcting proof of his evidence:—On looking at my paper on the subject, I find that in no case were the plague bacilli recoverable 21 days after burial.)

27,383. What was the season of the year?—These experiments with the plague bacilli are one of a whole series of experiments with typhoid, cholera, tubercle, bacillus prodigiosus, and staphylococcus aureus. Amongst the series are also experiments with the plague bacillus. That was done between May of last year and March of this year. The experiments extended over a considerable time.

27,384. Therefore the living bacillus exists actively for a long time in the dead body?—17 days, but certainly not so long as the popular belief would have it. I must say I do not quite understand the experiments which have been published with reference to the survival of the plague bacillus in earth. I should like to see those things done again.

27,385. (*Prof. Wright.*) Whose experiments are you referring to?—Hankin, I think, has published such, and Yersin himself made some statements with regard to this matter.

27,386. (*The President.*) You have not made any experiments?—No; Hankin could not recover it from earth.

27,387. Have you made any experiments with any other animals?—Rabbits and guinea-pigs only.

27,388. You have not investigated fleas or bugs?—No.

27,389. (*Mr. Hewett.*) Did I understand that you put the plague bacillus on earth, and that you were not able to recover it?—I placed it in a dead body in earth. We have made in the laboratory a large number of experiments with reference to many of these organisms in earth—bacillus prodigiosus, cholera, and typhoid—and the results are very remarkable in this way, that it is extremely difficult to recover them. They are very marked organisms, easily recoverable if present. You know how much more marked typhoid or prodigiosus is than the plague bacillus.

27,390. This applies to non-sterilized earth?—Yes. They were put directly into certain areas of soil of different kinds, and in a few days, or a few weeks, it is a matter of extreme difficulty to recover them.

27,391. (*The President.*) You have not made any definite experiments yourself?—No.

27,392. (*Prof. Wright.*) You have not made any experiments on clothing to see how long the infective material would remain in clothing?—No.

27,393. Do you kind that the plague bacillus is soon killed by desiccation?—I have made a few experiments with the plague bacillus, and, being a non-sporing bacillus, if it is desiccated in a thin film it dies immediately, just like many other non-sporing bacilli. Of course, it entirely depends on the thickness of the film. If you have a thick layer or a large lump—a piece of spleen—for instance, the possibility is that the centre remains undried.

27,394. (*The President.*) Have you found the bacillus in the blood of animals?—Yes.

27,395. In all parts of the circulation?—We generally use the heart's blood, and then we make sections of the organs and find them also in the blood vessels there.

27,396. Have you found them in the living animal?—Yes, in the blood.

27,397. Have you had much difficulty in finding the bacillus in living animals?—In the early stages, before 48 hours, I do not think we have succeeded in obtaining the plague bacilli from the blood, but on the last day of the animals' existence there was not very much difficulty in demonstrating them in the blood of the general circulation. I am speaking of cultivation.

27,398. Have you found the bacilli in any animals which recovered?—No.

27,399. Only in those which died, and shortly before death?—Yes, in those which were really afflicted, that is, animals which had a tumour and were quiet.

27,400. What is the longest interval before death that you have found the bacillus?—If an animal is injected subcutaneously in the groin with plague bacilli, there is generally a swelling already after 24 hours, and in this tumour plague bacilli can be easily demonstrated in large numbers, but in the blood of the general circulation of such an animal plague bacilli have not been demonstrated before 48 hours are over.

27,401. Have you tried the effect of chemical disinfectants?—Yes, I have tried Izal and carbolic acid, 2 per cent. carbolic and 1 in 300 Izal, and in three minutes they both are capable of disinfecting completely.

27,402. Killing entirely?—Yes. It was the ordinary pure carbolic acid.

27,403. You kept them under observation for some considerable time?—Yes.

27,404. For how long?—The cultures were kept 10 days to a fortnight.

27,405. Will you describe the experiments with disinfectants?—We generally use pure cultures of the material—24-hour agar culture, grown at 37° C. in order to ensure having active microbes. A particle of it is taken off and put in the disinfecting solution, which had been put previously into a sterile test-tube; a particle of the growth is put in and well shaken up so as to distribute it uniformly. It generally distributes very rapidly. It is then kept in this condition for five minutes; after this a considerable amount of it is taken out, two or three loops—which would, if the solution were water or salt, yield an innumerable number of colonies—and with it nutritive media (agar or broth, or both) are infected. These are then put into the incubator at 37° C., and the result watched. If only a few colonies come up, we should say that a great many of the microbes had succumbed, but that some few had survived the action of the disinfectants; but if no colonies at all come up, then we say there were no living microbes left. If you make such an experiment that is to have scientific value, you have to use definite pure cultures and not merely material which contains these microbes. The only disinfectant experiments on the plague bacilli that I made were with carbolic acid 2 per cent. and Izal 1 in 300.

27,406. In your experiments on the two species of animal you found that the susceptibility of a rabbit was different from that of a guinea-pig?—Yes, a rabbit is more susceptible than a guinea-pig.

27,407. How did you dose them?—We gave them a good dose so as to ensure a positive result.

27,408. You mean you gave the rabbit the same dose as you gave the guinea-pig?—We give them always a much bigger dose than would be required to kill them.

27,409. Then you do not know what the amount which is required to kill them is?—No, only the duration of the disease. I could not put my hand on the rabbit experiments, but I could look them up in my note-book. I know, in order to ensure a fatal result, we always gave them a dose which was larger than was exactly the fatal dose.

27,410. You made no attempt to determine the smallest quantity?—No; we do not know what is the highest or the lowest quantity.

27,411. How did you come to any conclusion as to the difference of susceptibility? By weight?—Yes. We weighed the animals and accordingly gave the amount of dose.

27,412. What amount of dose?—$\frac{1}{10}$th, $\frac{1}{12}$th, or $\frac{1}{20}$th of a culture.

27,413. And you varied that amount according to the weight?—Yes.

Dr. Klein, F.R.S.

20 May 1899.

27,414. And you found that the variation which held with the guinea-pig did not hold with the rabbits?—Yes.

27,415. (*Mr. Hewett.*) Can you give us any facts as to the case of plague alleged to have been landed at Plymouth from the *Golconda*?—On December 29th, 1898, I received four capillary tubes with blood taken from the finger of a patient landed at Plymouth from the *Golconda*. The material was brought to me by Dr. Bulstrode, Inspector to the Local Government Board, and was to be examined for the Medical Department of the Local Government Board, to which Department my report was sent early in January. Neither by microscopic examination, nor by culture, nor by experiment on animals, were any plague bacilli discovered in the above blood samples.

(Witness withdrew.)

LIST OF APPENDICES.

APPENDIX No. LV.

(*See* Question No. 17,798.)

NOMINAL ROLL

of INOCULATED and UNINOCULATED KHOJAS in BOMBAY, who died from PLAGUE and other causes from 20th April, 1898, to 21st December, 1898, compiled by Mr. ISMAIL JAN MAHOMAD.

INOCULATED. DIED OF PLAGUE.

28.4.98. Karmally Lootafally, age 10 years, died of plague at hospital.

5.8.98. Nanjee Taya, age 22, died of plague at Moondagali. *Inoculated in* 1897.

12.8.98. Mahomed Varin, age 37, died of plague at Bhendibazar. *Was twice inoculated this year, and twice inoculated last year,* 1897.

28.9.98. Valli Mahomed Karim, age 12, died of plague at hospital, residing at Diva off Thana. *Once inoculated.*

INOCULATED. DIED OF DISEASES.

17.5.98. Motibai, wife of Kasam Jan Mahomed, age 20, died of delivery at Durga Street.

25.5.98. Loopli Jivan Soorditha's daughter Viroo, age 2 years, died of diarrhœa at Mazagaon.

30.5.98. ? Kasam Karmaly Soojis' wife Khainsabai, died of consumption at Khoja Street. *Twice inoculated.*

9.6.98. Jan Mahomed Visram, age 45, died of (?), Khoja Street; died at Hospital of Jamsetjee Jeejeebhoy. *Once inoculated.*

14.6.98. Jaffer Lakha, age 32, died of paralysis at Durga Street. *Once inoculated.*

15.6.98. ? Avalbai, wife of Remtala Mitha, age 30, died of consumption at Dougri. *Once inoculated.*

3.7.98. ? Jainab, daughter-in-law of Jagga Visram, age 20, died of consumption and delivery at Khoja Street. *Was inoculated.*

9.7.98. ? Sakina Meetha Rahimtula, age 11, died of consumption at Dongri Street. *Once inoculated in* 1897.

16.7.08. Pirbhai Devan, age 50, died of asthma at Duncan Road. *Was inoculated.*

23.7.98. ? Janbai, wife of Neuji Jiva, age 65, died of asthma at Dongri. *Was inoculated.*

28.7.98. Ali Mahomad Karsan Bava, age 2, died of fever and cold at Pala Bazar. *Once inoculated.*

5.8.98. Hoosen, son of Abdula Nensi, age 8 months, died of diarrhœa at Durga Muhalla.

7.8.98. ? Foolbai, wife of Hoosen Taya, age 56, died of brain fever at Moondagali.

7.8.98. Ranjee Bhanjee, age 54, died of asthma at Khojagali.

7.8.98. ? Issa Ibraham Pardhan, age 2½ years, died of consumption at Kharak.

7.8.98. Kasam Poonja's granddaughter, Sakina, age 1½ months, died of convulsions at Furniture Bazar.

14.8.98. Kara Kanji, age 35, died of (?) at Kandi Muhalla. *Once inoculated this year.*

18.8.98. ? Shubanali Kammoo Kurmali, age 24, died of consumption at Mazagaon H. A. compound yard. *Inoculated.*

20.8.98. ? Kamarbai, wife of Kasam Nathu Habooani, died of consumption at Pala Lane. *Once inoculated.*

23.8.98. Motibai, wife of Harji Nanji, age 18, died of (?) at Kandi Muhalla. *Twice inoculated.*

23.8.98. Hirbai, wife of Kanji Bhimji, age 56, died of brain fever at Kandi Muhalla *Inoculated.*

24.8.98. Aladina Bhahdina's wife Jaithbai, age 65, died of fever at Umarkhadi. *Once inoculated.*

3.9.98. Suntokbai, wife of Moona Nathu, died of (?) at Bhendibazar. *Inoculated twice.*

10.9.98. Nagindas Mathuradas, age 34, died of brain fever at Bhuleshwar. *Twice inoculated.*

12.9.98. Hassan Rahimtula, age 28, died of prolonged illness of fever at Dongri. *Twice inoculated.*

15.9.98. Siribai, daughter of Soomar Bharmal, age 9, died of other fever at Pala Lane. *Twice inoculated.*

16.9.98. ? Sonbai, wife of Kasam Manji, age 47, died of fever at Kharak. *Once inoculated.*

21.9.98. ? Ismail Rattansi, grandson Kasam Hassan, age 15, died of brain fever at Kandi Muhalla. *Twice inoculated.*

25.9.98. Dhanji Rooga, age 75, died of asthma at Kandi Muhalla. *Twice inoculated.*

29.9.98. Fatma, wife of Mahomed Nanjee, age 17, died of consumption. *Twice inoculated.*

14.10.98. ? Jaffer Lila Devji's daughter Fatma, age 10, died of fever at Kandi Muhalla. *Thrice inoculated.*

18.10.98. ? Daughter of Pundit Siv Dayal, Sakina, age 5 years, died of fever at Mazagaon at H. H. *Once inoculated.*

26.10.98. ? Sakina, daughter of Khanji Lalji, age 10, died of brain fever at Pala Bazar. *Once inoculated.*

4.11.98. Jaina, daughter of Mahomad Karim, age 5 years, died of diarrhœa at Dongri. *Twice inoculated.*

4.11.98. Jaina, daughter of Samsoodin Bhajin, age 4, died of diarrhœa at Dongri Bazar. *Once inoculated.*

6.11.98. ? Vally Jamal, age 32, died of fever at Durga Muhalla. *Once inoculated.*

8.11.98. ? Kajbai, wife of Hirji Fakir, age 25, died of delivery at Durga Street. *Twice inoculated.*

15.11.98. ? Karim Nathu Shivji's wife, Mariambai, age 25, died of consumption at Durga Muhalla. *Once inoculated.*

18.11.98. Mariambai, wife of Jan Mahomed Gangji, died of (?) at Moonda Gali. *Once inoculated.*

18.11.98. Khatza, daughter of Rahimtoola Khimji, age 22, died of asthma at Palki Muhalla. *Twice inoculated.*

22.11.98. ? Sakinabai, wife of Mahomed Alloo, age 24 years, died of delivery at Durga Street. *Once inoculated.*

23.11.98. Sonbai, mother of Goolam Hoosen Moolji, age 72 years, died of asthma at Durga Street. *Once inoculated.*

27.11.98. Sakinabai, wife of Allarakhia Gangji, age 25, died of consumption at Durga Street. *Once inoculated.*

28.11.98. Sakinabai, wife of Canji Lalji, age 27, died of Pala Lane. *Once inoculated.*

29.11.98. Minbai, wife of Hassan Megji, age 45 died of consumption at Furniture Bazar. *Once inoculated.*

NON-INOCULATED. DIED OF PLAGUE.

28.4.98. Jaffer Poonja, age 50, died of plague at hospital. Had come from Bandra.

1.5.98. Goolam Hoosen Alarakhia, age 20, died of plague at hospital. Had come from Bandra.

12.5.98. Manji Khimji, age 30, died of plague at hospital. From Bandra.

28.8.98. Navroj Ladha Sachoo, age 22, died of plague at hospital. Resident of Mandvi. Plague caught at Bombay.

31.5.98. Mahomad Rahim Manji, age 16, died of plague at Dongri Street.

2.6.98. Ladha Lachoo's wife, age 50, died of plague at hospital. Residence of Manori.

24.7.98. Kasam Mahomad Hassan, age 14, died of plague at Hospital. Came from Danda with plague.

9.8.98. Sherbanoo, granddaughter of Haji Lalji age 12, died of plague at Khoja Street.

19.8.98. Remtala Sajan, age 56, died of plague at Durga Street.

19.8.98. Kesarbai, wife of Goolansan Abbhai, age 35, died of plague at Durga Street.

20.8.98. Roopsy Virjee, age 38, died of plague at Pala Lane.

21.8.98. Lonbai, wife of Mahomed Premji, age 55, died of plague at Pala Lane.

23.8.98. Hoosen Jaffer Ibrahim, age 23, died of plague at Kharak.

25.8.98. Jaffer Mariambai, wife of Hoosen, age 15, died of plague at Kharak.

27.8.98. Cooverbai, wife of Khan Mahomed Simji, age 25, died of plague at Kharak.

28.8.98. Kasam Ramji Boga, age 18, died of plague at Durga Muhalla.

1.9.98. Alladin Hassan's mother, age 60, died of plague at Dongri.

1.9.98. Jamabai, wife of Haji Nathoo, age 40, died of plague at hospital.

2.9.98. Pirbai Karmali, age 23, died of plague at Pala Lane.

4.9.98. Babool Ramji Canji, age 18, died of plague at Pala Bazar.

4.9.98. Mithibai, wife of Jooma Kara, age 30, died of plague at Dongri.

6.9.98. Ibrahim Shariff, age 64, died of plague at Durga Street.

7.9.98. Alli Ghiga, age 50, died of plague at Kharak.

7.9.98. Kasam Nathoo, Manji, age 29, died of plague at Furniture Bazar.

7.9.98. Virji Khimji, age 65, died of plague at Kharak.

9.9.98. Virji Khimji's daughter Sakina, age 15, died of plague at Kharak.

10.9.98. Abdoola Karim, age 40, died of plague at Dongri.

12.9.98. Lalbai, wife of Hassan Karim, age 40, died of plague at Dongri Street.

12.9.98. Manji Dhanji, age 19, died of plague at Pala Bazar.

13.9.98. Meheralli Rattansi, age 16, died of plague at Kharak.

22.9.98. Karmali Hassan Megji, age 12, died of plague at Dongri.

25.9.98. Mahomed Hasan Shivji, age 23, died of plague at Durga Muhalla.

24.9.98. Jaffer Ibrahim, age 38, died of plague at Durga Muhalla.

28.9.98. Ramjanalli Karmali, age 19, died of plague in hospital at Dongri.

28.9.98. Mooraj Alloo, age 25, died of plague.

28.9.98. Karmali Rahim, age 12, died of plague at hospital.

28.9.98. Daughter of Bundealli Allarakhia, age 10, died of plague at Durga Street.

29.9.98. Moosa Kasam Karim, age 39, died of plague at Dongri.

3.10.98. Bhanji Hasanaly Sowcar, age 18, died of plague at Pala Bazar.

22.10.98. Ismail Jaffer Nathoo, age 28, died of plague at Dongri.

12.11.98. Ali Ibrahim Mahomad, age 20, died of plague at Dongri.

17.11.98. Jan Mahomed Ramji, died of plague at Bhendibazar (died at hospital.)

15.12.98. Shivji Nanji Visram, age 25, died of plague at Pala Lane.

NON-INOCULATED. DIED OF DISEASES.

23.4.98. Fatma, wife of Abdala Ismail, age 28, died of consumption at Durga Muhalla.

24.4.98. Alibhai Hassan Khimji, age 20, died of consumption at Kandi Muhalla.

25.4.98. Aloo Meraly's son, age six months, died of fever at Mazagaon.

25.4.98. Lale Soonar's daughter, age 4 months, died of convulsion at Dongri Street.

26.4.98. Virbai, wife of Virji Haboo, age 70, died of consumption and sore throat at Palla Gali.

27.4.98. Minbai, wife of Ravji Sanga, age 55, died of heart disease at Durga Muhalla.

27.4.98. Wala Devji's son, age 1½ years, died of fever at Kharak.

— Dhala Lachoo's son, age 1 month, died of convulsion at Durga Muhalla.

28.4.98. Piarally Abdala's son, age 1½ years, died of consumption at Kharak.

28.4.98. Mitha Premji's brother's daughter, age 1 year, died of convulsion at Durga Street.

29.4.98. Mirza Ali Khan Mahomad, age 30, died of consumption at Durga Muhalla.

29.4.98. Ismal Meraly's son, age 4 months, died of convulsion at Durga Street.

30.4.98. Goolam Hoosen Mahomad Versi, age 4 months, died of fever at Dongri.

1.5.98. Mahomadbhoy Ravji, age 40, died of heart disease at Khoja Molla.

3.5.98. Kasam Jan Mahomad's daughter, age 1 month, died of convulsion at Durga Street.

4.5.98. Fazal Noor Mahomad's grand-daughter Mariam, age 4 months, died of convulsion at Kharak.

4.5.98. ? Sherally Pirbhais' son Jainatabdin, age 3 years, died of convulsion at Durga Muhalla.

— Alibhai Karmally Soorji, age 46, died of consumption at Khoja Muhalla.

5.5.98. Sonbai, wife of Walji Ramji, age 60, died of consumption at Durga Muhalla.

— Khatijabai, daughter of Ladha Remtala, age about 6 months, died of cough at Dongri.

7.5.98. Lootafally Karmally's daughter, age about a month, died of diarrhœa at Durga Street.

7.5.98. Karmally Fazal, age 98, died of asthma at Israel Street.

10.5.98. Kasam Nanji, age 45, died of consumption at Durga Muhalla.

10.5.98. Suleman Rahim's wife, age 35, died of consumption at Durgadevi.

11.5.98. Abdala Ladha Chatoo's daughter Sakina, age 12 months, died of convulsion at Pala Lane.

12.5.98. Motibai Kanji, age 22, died of consumption at Kandi Muhalla.

13.5.98. ? Goolam Hoosen Ebram Walji, age 1½ years, died of fever at Mazagaon.

14.5.98. Aladin Kasam Khimji, age 40, died of liver complaint at Dongri.

14.5.98. Karim Panchan's wife Aval, age 32, died of consumption at Mazagaon. *Once inoculated.*

14.5.98. Chatoo Visram, age 70, died of consumption at Durga Street.

14.5.98. Abdala Fazal, age 15, died of fever at Durga Street.

15.5.98. Mahomad Bhagbaria, age 35, died of paralysis at Palagali.

16.5.98. Fatma, daughter of Ragooji Jamal, died of convulsion at Durga Street, age 72.

16.5.98. Dost Mahomad Hassan Noor Mahomad, age 5, died of fever at Moonda Gali.

18.5.98. Sakinabai, grand-daughter of Jessa Premji, age 14, died of brain fever at Durga Street.

18.5.98. Sakina, wife of Fazal Noor Mahomad, age 24, died of delivery at Kharak.

20.5.98. Mother of Noor Mahomad Khatri, age 75, died of fever at Darga Muhalla.

23.5.98. Aba Moloo, age 54, died of asthma at Durga Street.

23.5.98. Fazal Ladha Lalji, age 40, kidney disease at Khoja Muhalla.

24.5.98. Lalbai, wife of Ibram Sheriff, age 62, died of consumption at Durga Street.

24.5.98. Ibram, son of Remtula Koorji, age 9, died of asthma at Duncan Road.

25.5.98. Alarakhia Thaver, age 54, died of consumption at Kharak.

25.5.98. Mahomad Vally Jessa, age 2 years, died of convulsion at Durga Street.

26.5.98. Abdala grandson of Haji Sivji, age 12 months, died of convulsion at Durga Street.

26.5.98. Alarakhia Kanji's grandson, age 6 months, died of convulsion at Durga Street.

27.5.98. Hoosen Ali Lutafally of Kamria Mahomad Chotti, age 26 died of consumption at Dongri Street.

29.8.98. Wife of Premji Gangji Soolbai, age 60, died of diarrhœa at Pala Gali.

31.5.98. Grand-daughter of Khaki Radamsi, age 2 years, died of convulsion at Kharak.

3.6.98. Daughter of Fatehally Thaver, Bai Sherbanoo, age 12, died of consumption at Furniture Bazar.

3.6.98. Hoosen Alarakhia Jivray, age 7 months, died of convulsion at Khoja Street.

4.6.98. Bacheebai, daughter of Ismal Suji, age 4 months, died of diarrhœa at Dongri Street.

4.6.98. Jafferaly Aladin Kassam, age 2½ months, died of convulsion at Dongri Street.

6.6.98. Fazal Ibram's wife Jainab, age 39, died of fever at Khoja Street.

7.6.98. Fatma, wife, daughter-in-law of Premji Paroo, age 15, died of consumption at Khoja Street.

7.6.98. Nanbai, wife of Soomar Rajpar, age 60, died of diarrhœa at Dongri.

10.6.98. Bachoo, grandson of Mahomed Karim, age 8 months, died of convulsion at Byculla.

11.6.98. Kasam Hassan Mawjee, age 1 year, died of fever and convulsion at Umarkhadi.

12.6.98. Lowjee Canjee, age 22, died of ? at Kolaba.

14.6.98. Abdul Husen Mahomed Ibrahim Bhuloo age 1 year, died of convulsion at Khoja Street.

15.6.98. Mariam, daughter of Nowroj Lakha, age 7 months, died of convulsion at Dongri Street.

18.6.98. Jaffer Ismail Mahomed, age 8 months, died of fever at Durga Street.

18.6.98. Goolamalli Hoosen Ladak, age 5 months, died of convulsion at Dongri Street.

20.6.98. ? Dhanbai, daughter of Mahomed Jootha, age 12, died of consumption at Kandi Muhalla.

20.6.98. ? Moloo Mahomed Ladak, age 30, died of consumption at Kharak.

23.6.98. ? Fatma, wife of Lale Mahomed Ibrahim, age 28, died of consumption at Khoja Street.

23.6.98. ? Sakina, daughter of Lowji Daya, age 12, died of consumption at Dongri.

24.6.98. Nanjee Valji's son, age 8 months, died of fever at Umarkhadi.

24.6.98. Sheriff Dossa's daughter, age 3 months, died of convulsion at Kandi Muhalla.

27.6.98. Sherbano Rahim Assar, age 8 years, died of diarrhœa at Dongri Bazar.

28.6.98. ? Nanbai, wife of Jiva Soomar, age 48, died of consumption at Durga Street.

28.6.98. Joosab Karmali Haji Boga, age 10 months, died of convulsion at Khoja Street.

30.6.98. ? Daughter of Rajabally Jan Mahomed, age one week, died of ? at Kandi Muhalla.

3.7.98. Ahmed Gangji, age 25, died of consumption at Old Nagpada.

3.7.98. ? Fatma, grand-daughter-in-law of Simji, age 25, died of consumption at Market.

4.7.98. Khakoo Peerbhoy, age 65, died of liver complaint at Khoja Street.

6.7.98. ? Mahomed Khulphan's wife Walbai, age, age 28, died of consumption.

6.7.98. Mahomed Lowjee Visram's grandson, age 4 months, died of ? at Dongri.

6.7.98. ? Grand-daughter of Khakhoo Laljee, age 3 years, died of convulsion at Durga Street.

9.7.98. ? Rhematbai, wife of Dhanji Jairaj, age 60, died of consumption at Fhosabazar.

10.7.98. Daughter of Mahomed Jaitha, age 4 months, died of convulsion at Kandi Muhalla.

12.7.98. Goolam Hoosen Dharamsi Damji, age 15, died of ? at Pala Lane.

12.7.98. Bachoo Dhala Jivraj, age 15 days, died of convulsion at Kharak.

13.7.98. Jamal Jiva, age 45, died of ? at Dongri Street.

13.7.98. ? Koorbai, mother of Jan Mahomad Magji, age 85, died of fever at Khoja Street.

13.7.98. ? Fatma, grand-daughter-in-law of Bana Lila, age 24, died of fever at Kharak.

13.7.98. Bachi Allarakhia Virjee, age 2 months, died of purge at Byculla.

13.7.98. ? Mahomed Rowjee Aloo, age 2½ years, died of asthma at Durga Street.

14.7.98. Serenbai, daughter of Ladha Thaver, age 12, died of ? at Pala Lane.

15.7.98. ? Mongibai, wife of Karmali Jamal, age 16, died of consumption at Durga Street.

APPENDIX No. LV. (i.).

REPORT

BY

Dr. KHAJA ABDULLA,

REGARDING

THE KHOJA HOSPITAL, BOMBAY,

WITH

A LIST OF INOCULATED PERSONS TREATED IN IT.

I.

From the Secretary to the Indian Plague Commission to Dr. Khaja Abdulla, Khoja Hospital, Bombay, dated India Office, 28th July, 1899.

Sir,

I am directed to invite your attention to my letter, No. 969, dated March 27, 1899, to which no reply has as yet been received. The Commissioners will be obliged if you will send as early as possible, and if possible by next mail, to me at the India Office, London, the particulars you were asked to supply regarding anti-plague inoculation among the Khojas, viz.:—

(1) A list of those treated at the Khoja Hospital, showing the names of the inoculated Khojas who have had plague, giving the number and date of the inoculation of each person, the date of attack and admission, and the result of the disease, whether fatal or not; and

(2) The total number of uninoculated Khojas who have had plague, together with the mortality among them.

II.

To the Secretary, Indian Plague Commission, India Office, London.

Sir, Bombay, 18th August, 1899.

I have the honour to inform you that on the 15th of April last, I handed over to the late Khan Bahadur Mahomedbhoy Ebrahim, the founder of the Khoja Plague Hospital, as usual, to be sent to you, my report, together with the statistics about the inoculated and non-inoculated patients treated in the hospital. On the death of the founder of the hospital it was discovered that the said report was not sent to you, and the lawyers of the representatives of the deceased, at my request, returned to me the same on the 14th instant, a copy of which I beg to forward to you.

I have, &c.
Khaja Abdulla.

III.

To the Secretary, Indian Plague Commission.

Mahomedbhoy Ebrahim Plague Hospital for Khojas.
Bombay, 15th April, 1899.

Sir,

In reply to your letter dated 27th March 1899, I have the honour to submit the particulars about the patients treated in this hospital, both inoculated and non-inoculated.

Since the opening of the hospital on the 26th of April 1897 to 5th April 1899, 347 plague patients were treated in the hospital, out of which 62 cases were inoculated. Some of the patients produced certificates of inoculation, others did not produce any certificate, but the relatives and guardians of the patients declared the information of the fact of their being inoculated. The list herewith annexed gives all particulars in our possession regarding cases of inoculated persons. Of the 62 inoculated cases treated for plague, 24 proved fatal, 33 recovered, and 5 remained under treatment up to the 5th April, 1899.

Since the opening of the hospital, up to the 15th January, 1898, 77 patients, both inoculated and non-inoculated, were treated with ordinary mercurial and stimulant treatment, out of which 48 died, and 29 recovered. From the 15th January 1898, to the 5th April 1899, 209 non-inoculated patients were treated with native Indian drugs and occasional doses of stimulants, out of which 84 were discharged cured, 12 were still under treatment on the 5th April, 1899, and 113 died.

Of the total number of cases treated, two were treated by Dr. Galeotti with Lustig's curative serum, both of which proved fatal.

I have, &c.
Khaja Abdulla.

IV.

List of Inoculated Patients treated in the Khan Bahadur Mahomedbhoy Ebrahim Khoja Plague Hospital Bombay, from the Date of its Opening, *i.e*, 26th April 1897, up to 5th April 1899.

No.	Name.	Age.	Sex.	Residence.	Date of Inoculation.	Date of Attack.	Date of Admission.	Date of Death.	Date of Discharge.	Remarks.

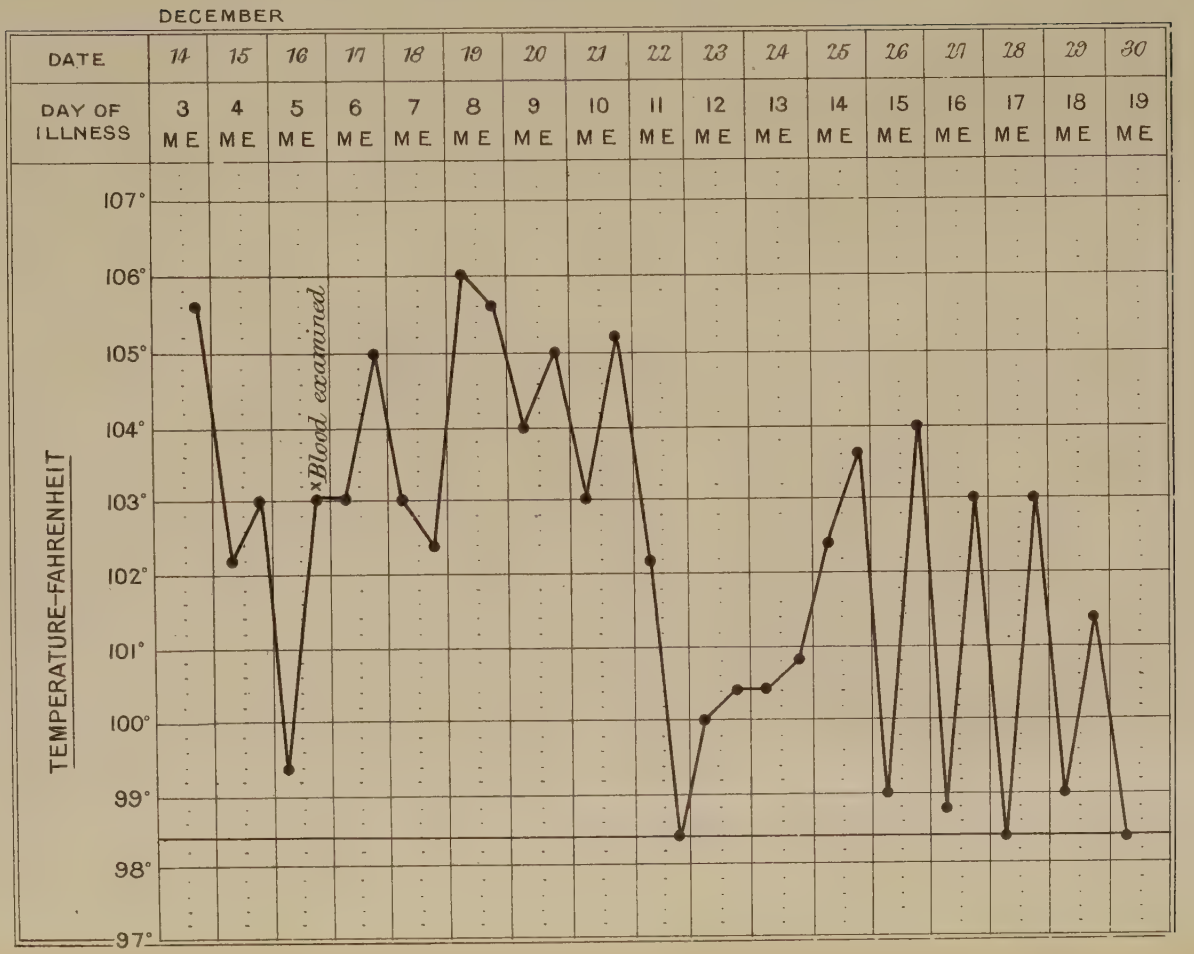
CASE OF PLAGUE SEPTICÆMIA.

THE ORGANISM RECOVERED FROM THE BLOOD ON 5TH DAY

CONVALESCENCE AND RECOVERY OF PATIENT



POONA PLAGUE HOSPITAL.

December, 1897.

Male, aged 40, small bubo left femoral region. Patient under a pronounced toxæmia on admission. Pulse feeble. Later (6th day) became semi-comatose and lung showed involvement on 5th day.

Small quantity of blood from vein at back of hand removed by pipette and inoculated on to agar. Four tubes inoculated, each tube yielded colonies of the plague micro-organism within 48 hours' incubation at 37°C. Characteristic broth cultures obtained. A quantity of 24 hours' old broth culture (·25c.c.) inoculated into a rat caused death of animal within 48 hours. Cultures of the plague micro-organism obtained from the blood of the rat.

Crisis on 11th day followed by fever of suppuration up to 19th day. After this slowly convalesced, and was dismissed well 45 days after admission.

CASE OF PLAGUE SEPTICÆMIA.

THE ORGANISM RECOVERED FROM THE BLOOD ON 6TH DAY

CONVALESCENCE AND RECOVERY OF PATIENT

POONA PLAGUE HOSPITAL.

January–February, 1898.

Male, aged 22, bubo in right axilla. Ill for two days before admission. Powerfully built man, lay in dorsal decubitus, semi-conscious, pupils contracted, pulse rapid, but of fairly good quality.

On morning of 6th day of illness small vein at back of left hand opened, and quantity of blood pipetted into sterile tube. Three agar tubes inoculated with the blood, and incubated at 37°C. At end of 24 hours two of the tubes showed several colonies, third tube only showed growth after 48 hours.

Microscopic appearances of growth characteristic of plague. Inoculated a rat with ·25c.c. of broth culture. Rat died of plague within 48 hours.

Four smear preparations of the fresh blood of patient showed the presence of bacteria, resembling B. Pestis in three.

Toxæmic symptoms present on admission lasted till 8th day of illness. Patient kept alive by nasal feeding. Made a good recovery.

E. L. MARSH.

* The figures given in roman type against Belgaum and Dharwar for 1898 are for 11 months. The plague figures are for the entire year.

APPENDIX No. LVIII.

NOTES AND CHARTS

by

MR. N. A. F. MOOS,
DIRECTOR OF THE KOLABA OBSERVATORY, BOMBAY,

on

the RELATION of PLAGUE and METEOROLOGICAL CONDITIONS in BOMBAY,

With a Note by

DR. BUCHAN,
SECRETARY TO THE METEOROLOGICAL SOCIETY FOR SCOTLAND.

I.

SOURCE and EXPLANATION of the METHODS of REDUCTION of ENTRIES in the TABLES 1–5 and PLATES A, B, B (i.), B (ii.), and C.

In compiling the following tables, the entries given in the published volumes of observations at the Government Observatory, Kolaba, have been invariably adopted. It is only where a few entries were not so available, that the original manuscript abstracts were consulted and the missing entries filled in. In every case the modes of operation have been precisely the same as those adopted in reducing the entries given in the printed volumes, and in no case has a new departure from the usual methods been attempted.

TABLES 1 AND 2.

Barometer and Temperature of the Air.

1846.—Monthly means were taken from the manuscript abstracts from which annual means were calculated and adopted. All other entries of the year have been taken from the manuscript abstracts directly.

1847–1895.—From 1847 to 1872, all entries have been taken directly from the Meteorology of the Bombay Presidency, and from 1873 to 1895, from the volumes 23 to 34 of Bombay Magnetical and Meteorological Observations.

TABLE 3.

Pressure of Vapour.

1846.—Monthly means of dry and wet-bulb thermometers taken from manuscript abstracts were reduced to monthly means of pressure of vapour by the formula given in the Meteorology of the Bombay Presidency for the years 1847 to 1861. The maxima and minima were derived by a process of inspection and reduced as above.

1847–1895.—From 1847 to 1872, the entries have been taken directly from the Meteorology of the Bombay Presidency, and from 1873 to 1895, from Volumes 23 to 34 of Bombay Magnetical and Meteorological Observations.

TABLE 4.

Wind.

1846.—Monthly means of pressure in lbs. per square foot were taken from manuscript abstracts from which the annual mean was calculated and adopted. Hourly, daily, and monthly maximum pressures were directly obtained from the abstracts and adopted. For the average direction of the year, instead of getting the daily average from 24 hourly observations, a particular mean hourly direction was selected which corresponded with the average direction of the day, to which the usual average process was applied, and from the monthly means so derived the annual mean was finally obtained and adopted.

1847–1872.—Annual mean pressure in lbs. per square foot for the years 1847 to 1865, given in Volumes 3 to 22 were taken directly and adopted, as also the annual average directions for the years 1847 to 1863. The force of wind in eight principal directions during the years 1864 and 1865, and in 16 directions in the years 1866 and 1867, as given in the Volumes 21 and 22, were taken and resolved into north and east components, and resultant directions were found therefrom and adopted. Annual mean velocities for 1866 to 1872, as given in Volumes 22 and 23, were directly adopted. Mean resultant directions for 1868 to 1872 were derived from the annual components of wind given in Volumes 22 and 23, and adopted. All other entries for 1847 to 1872 were directly taken from the Meteorology of the Bombay Presidency.

1873–1895.—Annual mean velocities and maximum mean daily and monthly velocities have been taken from Bombay Magnetical and Meteorological Observations, Volumes 23 to 34. Mean resultant directions were reduced from the annual components of wind given in the above volumes and adopted. Maximum hourly mean velocities were derived from data prepared for the yearly Government administration reports.

TABLE 5.

Rainfall.

1846–1872.—All entries have been taken directly from the Meteorology of the Bombay Presidency, except that of maximum *daily* rainfall for the year 1846, which was taken from manuscript abstracts.

1873–1895.—All entries have been taken from Volumes 23 to 34 of the Bombay Magnetical and Meteorological Observations.

PLATES A, B, B (i), and B (ii).

Variations of the Temperature of the Air and Ground.

The accompanying plates have been put in to show that what is true for the yearly variation of ground evaporation is true also for the day. In the yearly fluctuations the resulting curve shows that in the colder and drier months the ground evaporation is a maximum, and in the hotter and moist months it is a minimum. The Tables A. and B. will show that during the day the worst hours are the early morning hours, when the temperature of and the tension of moisture in the air is a minimum; and the best hours are the afternoon hours, when both the temperature and tension of moisture are a maximum.

PLATE C.

Movement and Intensity of Wind.

In regard to Plate C., which represents the movement of wind and measures the intensity from hour to hour of land and sea breezes, it may be noted that this factor supplies a valuable health giving component, *ozone*, and should be adequately represented in any curve which is drawn to run coincident with the mortality curve. Unfortunately the treatment adopted in this inquiry gives the curve in terms of either pressure or temperature, and the velocity being a factor of a different order, it cannot be compounded with the above. The only possible way, therefore, to include this factor in the curve is by finding the ratio of the velocity in terms of temperature by the method of least squares, a ratio which gives the resultant curve coincident with the mortality curve with the least probable error. As such computations are heavy, no systematic effort has been made except in an arbitrary, rough manner, the result of which is shown by dotted curves in the series of trial curves which I have prepared.

Statement of Mean Values and Charts A. and B.

The tables 1 to 5 and the plates A. to C. are followed by a statement of the weekly mean values of the meteorological factors used in the calculations, and the result of the calculations is appended in Chart A., which gives a series of trial curves, and in Chart B. which gives the curves for plague mortality and ground evaporation in Bombay.

N. A. F., Moos,
Director,
Government Observatory, Bombay.

PLATE A.

DIURNAL VARIATION IN THE TEMPERATURE OF THE AIR, (1866 TO 1872.)

From Observations recorded at the Kolaba Observatory, Bombay.

INEQUALITIES AT DIFFERENT HOURS IN THE SAME MONTH.

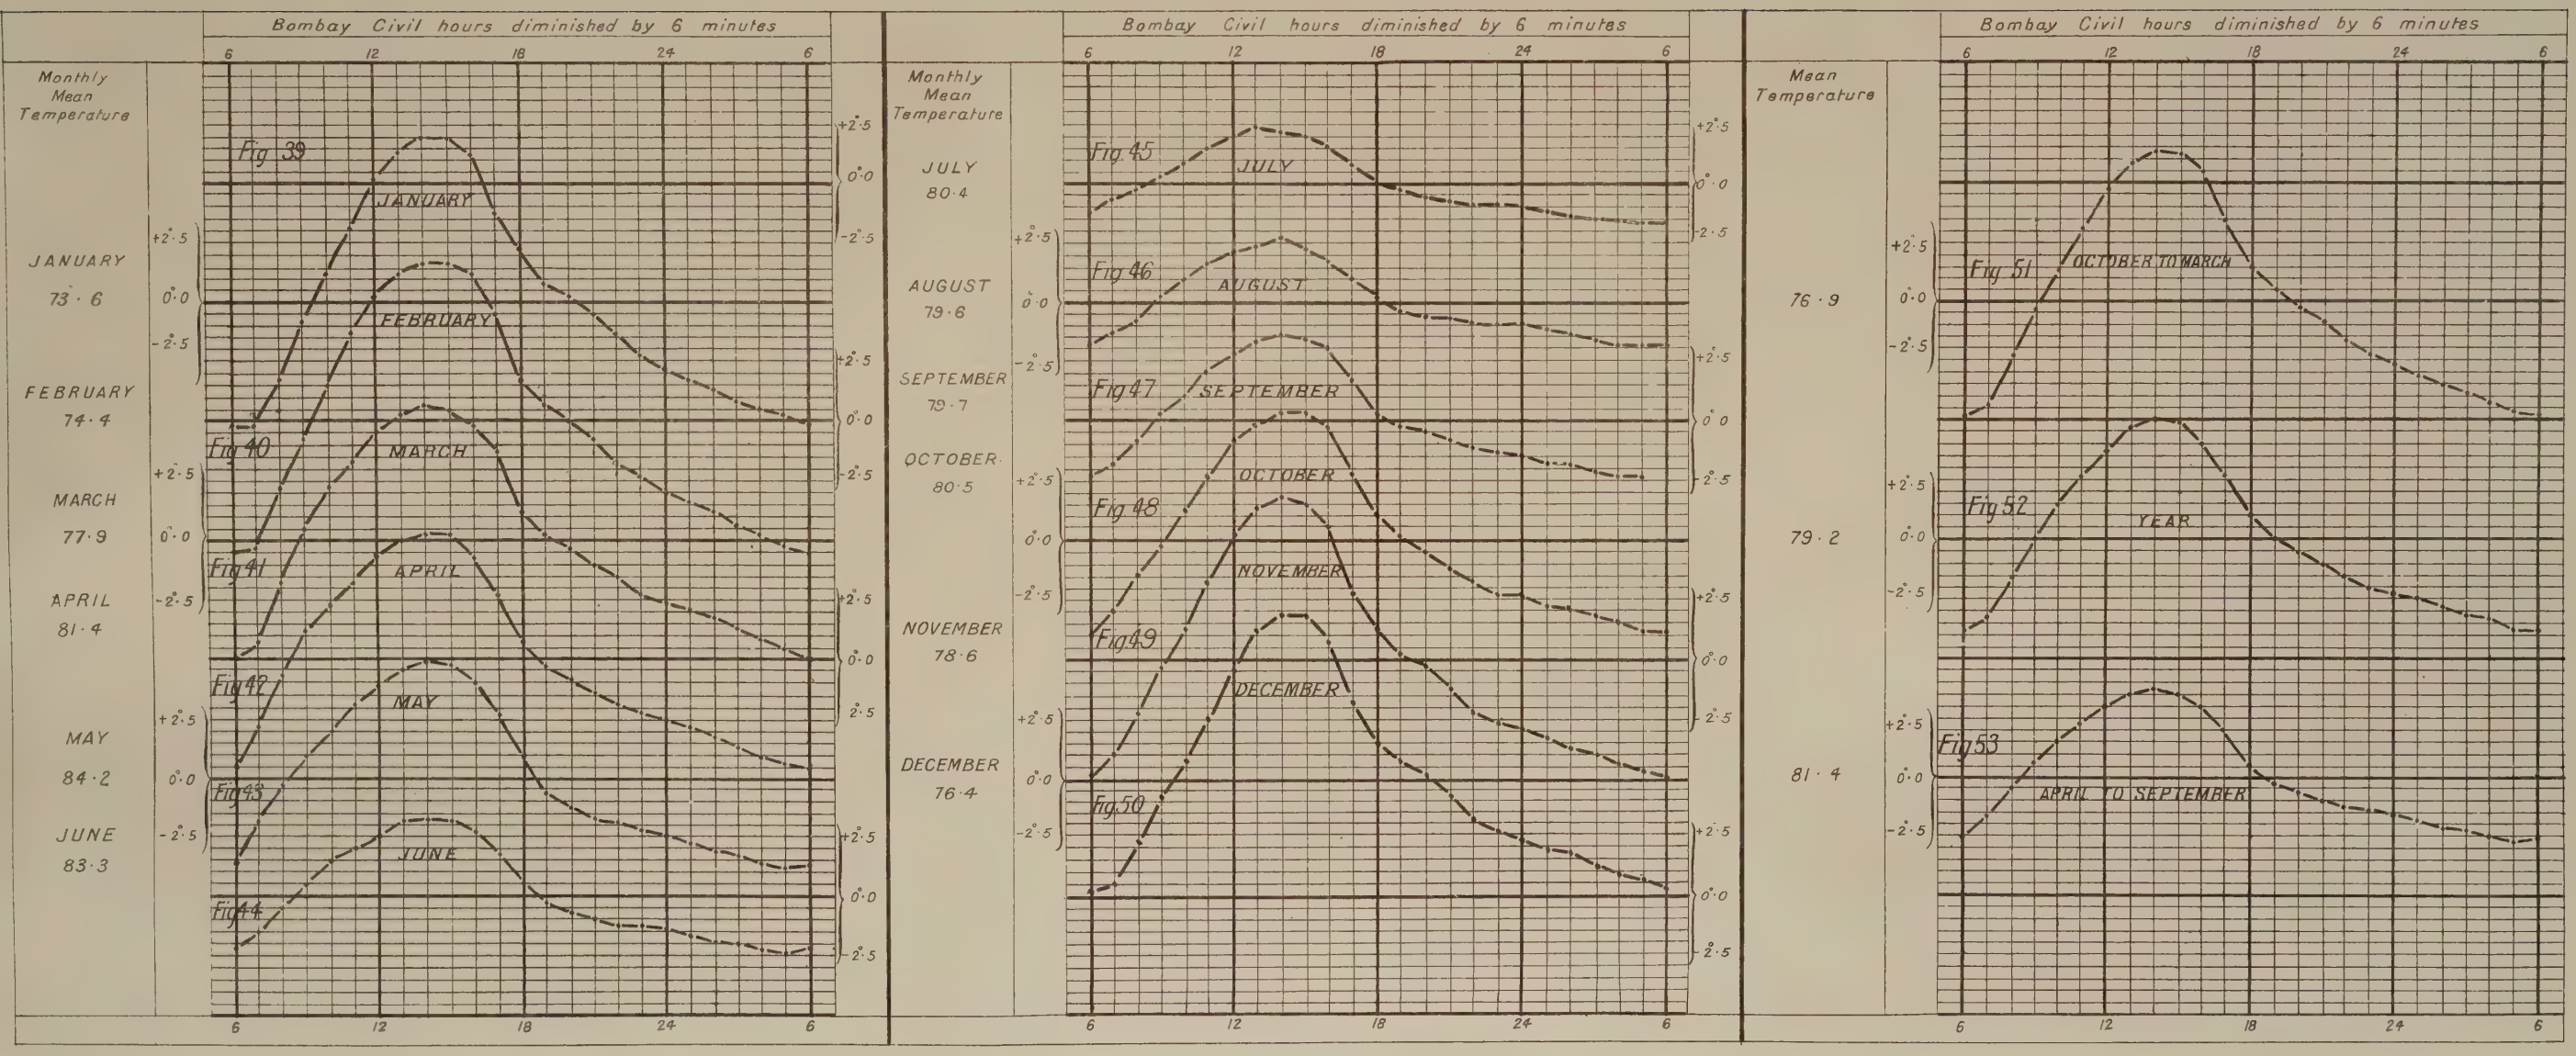

PLATE B

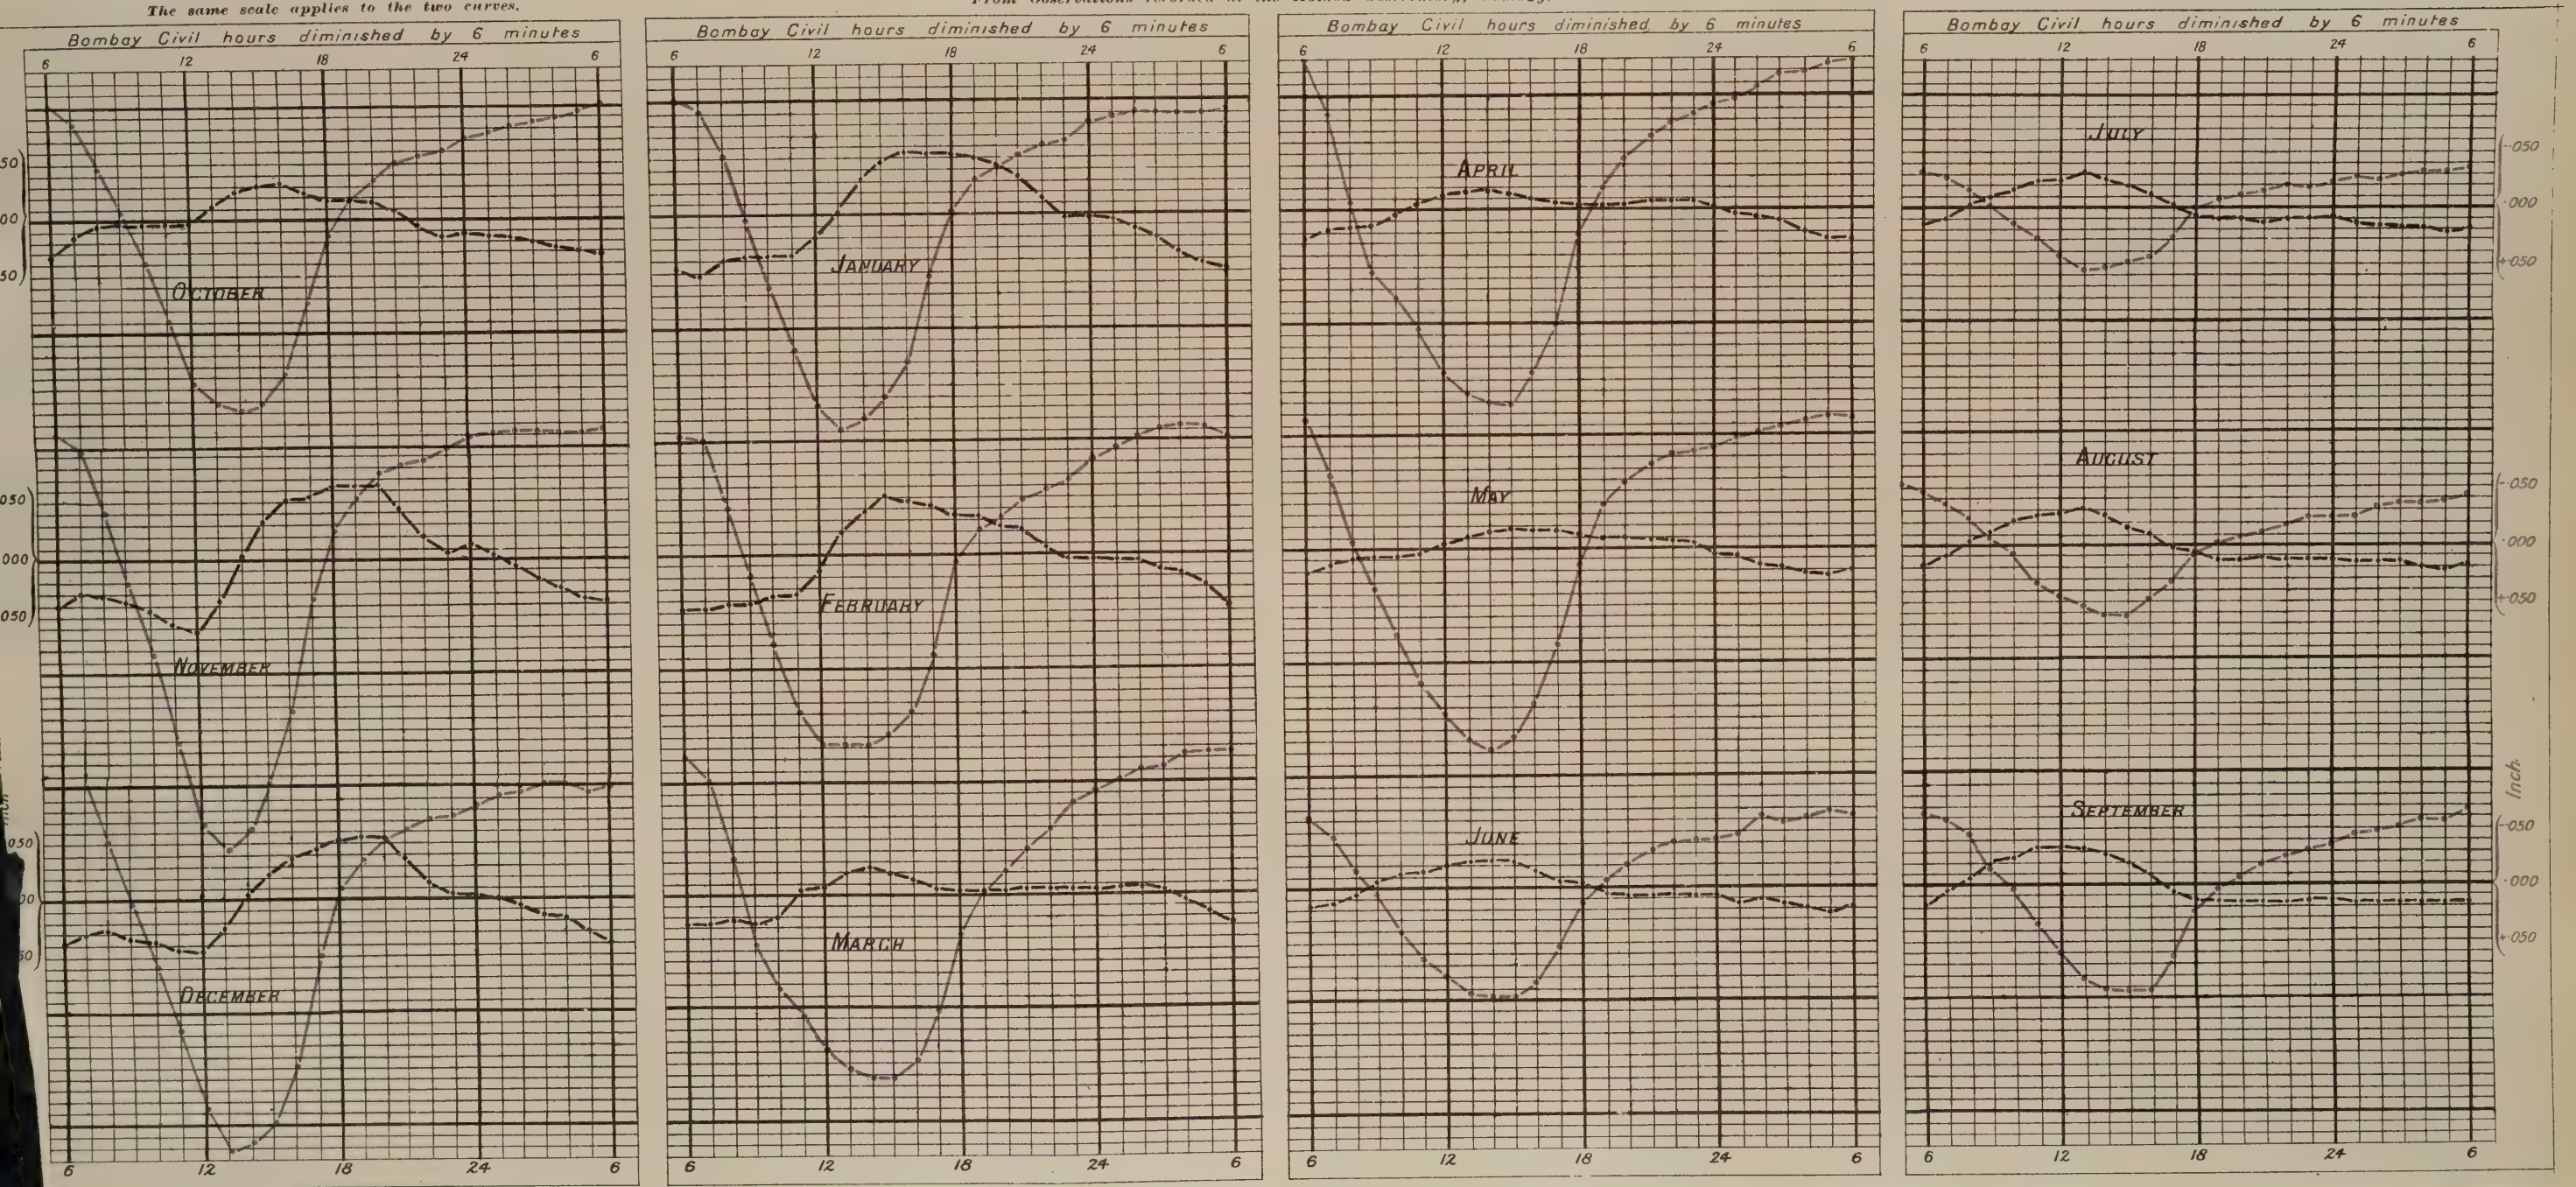
VARIATIONS IN THE TEMPERATURE OF THE GROUND.

From Observations recorded at the Kolaba Observatory, Bombay.

Pressure of vapour *Diurnal variation (1866 to 1872)* *Black curves.*
Additional capacity *Diurnal variation (1866 to 1872)* *Violet curves.*
Inequalities at different hours in the same month.
The same scale applies to the two curves.



Pressure of vapour *Diurnal variation (1866 to 1872)* *Black curves.*
Additional capacity *Diurnal variation (1866 to 1872)* *Violet curves.*
Inequalities at different hours in yearly and six-monthly periods.

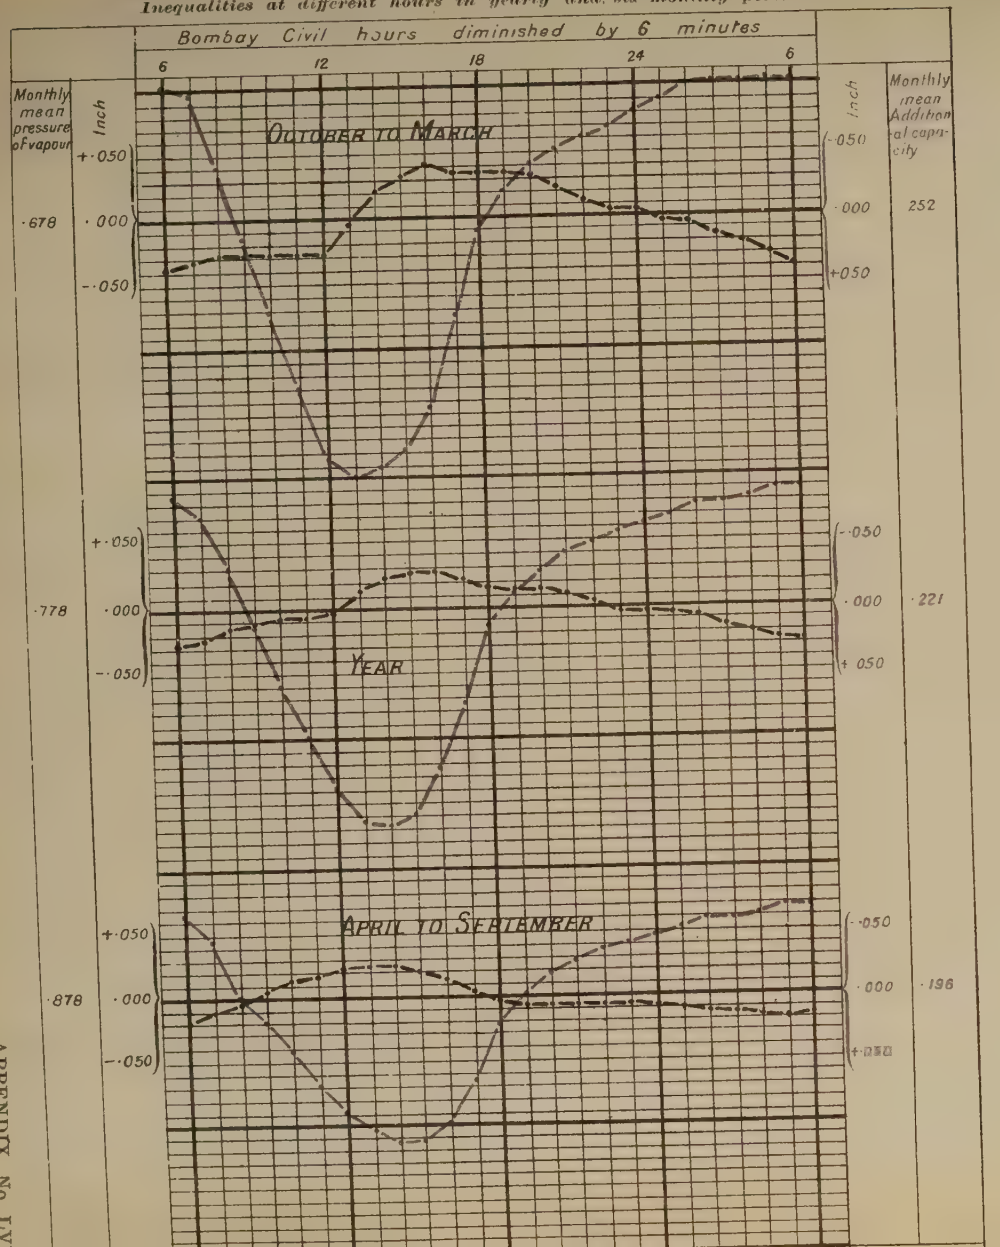


TABLE OF MONTHLY AVERAGES.

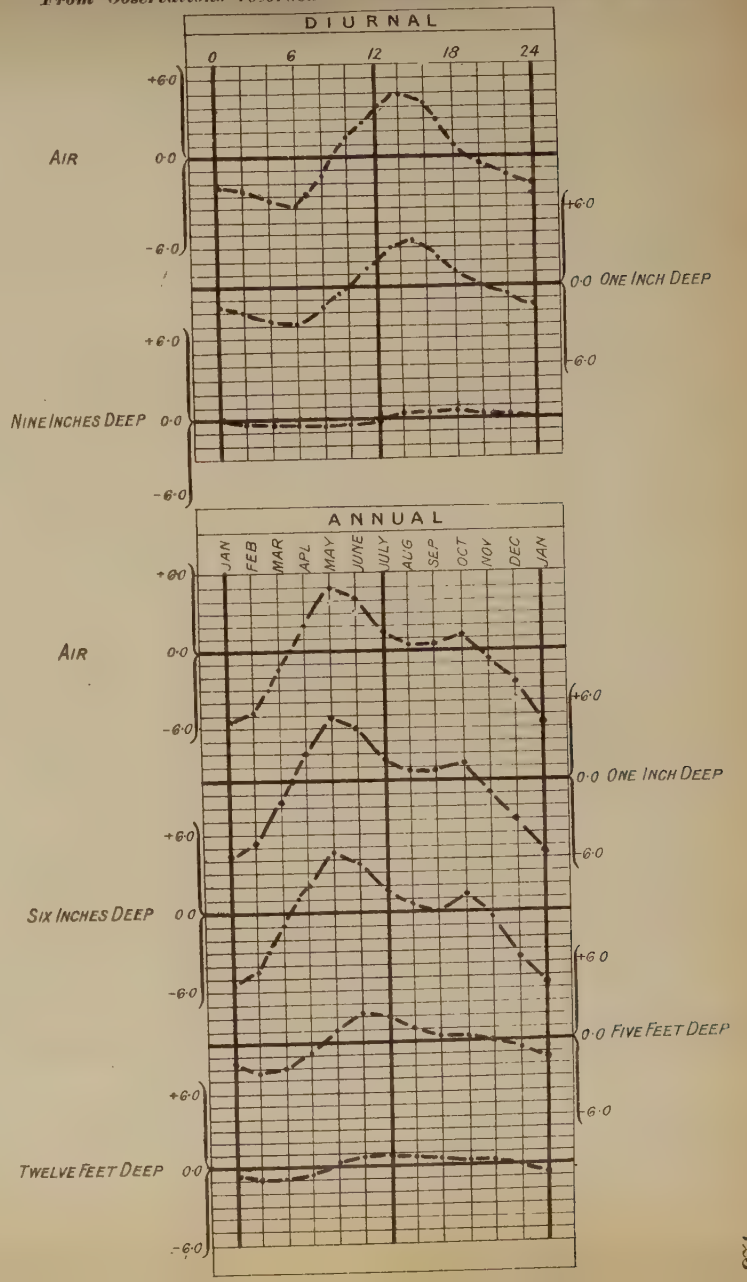
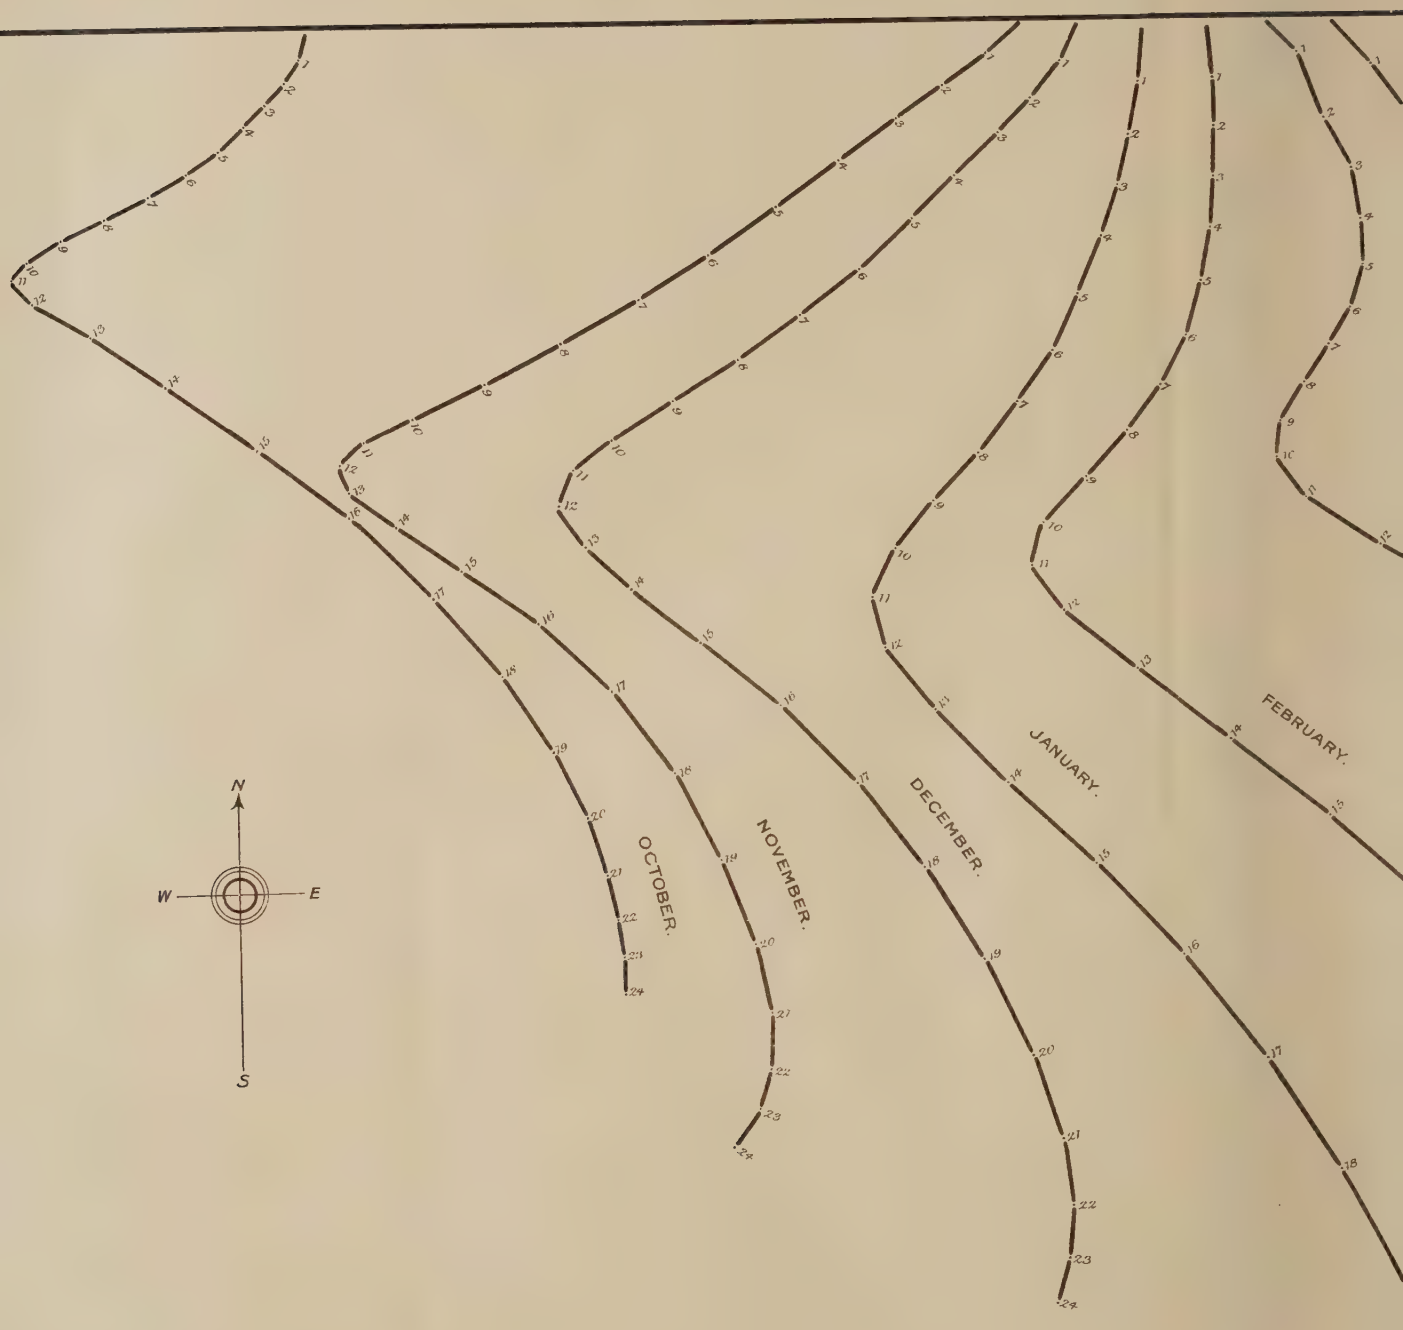
Month.	Monthly mean pressure of vapour.	Monthly mean additional capacity.
October	·847	·198
November	·692	·292
December	·644	·271
January	·587	·249
February	·595	·262
March	·707	·254
April	·811	·266
May	·874	·303
June	·931	·212
July	·904	·133
August	·882	·128
September	·869	·146

VARIATIONS IN THE TEMPERATURE OF THE GROUND.

From Observations recorded at the Kolaba Observatory, Bombay.





Scale: 15 miles to an inch.

PLATE C.

SHOWING THE MOVEMENT AND INTENSITY OF THE WIND.

From Observations recorded at the Kolaba Observatory, Bombay.

The Curves show the track, during the twenty-four hours of the typical days of each of the months October to April, of an imaginary balloon, moving always in the direction and with the velocity of the normal wind at Bombay.

The figures placed along the Course of the Curves mark the hours of the Bombay Civil day.

APPENDIX, No. LVIII.

Eyre & Spottiswoode. Lith. London

STATEMENT

SHOWING

THE WEEKLY MEAN VALUES

OF

DIFFERENT METEOROLOGICAL FACTORS

AND

OFFICIAL FIGURES OF MORTALITY

USED IN THE PREPARATION OF THE

FOLLOWING CHARTS.

STATEMENT showing the WEEKLY MEAN VALUES of different METEOROLOGICAL FACTORS used in the CALCULATIONS and FIGURES of MORTALITY published in the "GOVERNMENT GAZETTE."

Abbreviations:—t = Temperature of air; t′ = Temperature of evaporation; T = Temperature of dew point; t_{20} = Temperature of ground at 20″ depth; t_{60} = Temperature of ground at 60″ depth; F, f′ = Tension corresponding to saturation of T, t′; P = Weekly atmospheric pressure.

Date for the Week ending	t.	t′.	T.	t_{20}.	t_{60}.	$F = f' - a(t - t')\frac{P-f'}{30}$.	1 − F, or 1 − Col. 7.	$t_{20} - t$, or Col. 5 − Col. 2.	$t_{60} - t$, or Col. 6 − Col. 2.	$t_{60} - t'$, or Col. 6 − Col. 3.	$t_{60} - T$, or Col. 6 − Col. 4.	T − (t_{20} − t). In Terms of Temperature, or Col. 4 − Col. 9.	T − (t_{20} − t). In Terms of Tension corresponding to Temperatures.	T − (t_{60} − t). In Terms of Temperature, or Col. 4 − Col. 10.	T − (t_{60} − t). In Terms of Tension corresponding to Temperatures.	P.	Wind.	Pressure of Vapour derived from the formula, $F' = f' - a(t_{60} - t')\frac{P-f'}{30}$.	Dew Point corresponding to F′.	Mortality Figures as given in "Government Gazette."	Mortality Figures, Average of Five previous Years corresponding to Col. 19.	Mortality Figures from 7th August 1894, Average of Five previous Years, as given in "Government Gazette."	Mortality Figures from 2nd August 1897, Average of Five previous Years, as given in "Government Gazette."	Mortality Figures, Daily Average derived from Col. 22.	Col. 8 × Col. 10.

Table showing the Weekly Mean Values of different Meteorological Factors—*continued*.

Date for the Week ending.	t.	t'.	T.	t_{20}.	t_{60}.	$F' = f' - a\,(t-t')\frac{P-f'}{30}$.	1−F, or 1−Col. 7.	$t_{20}-t$, or Col. 5−Col. 2.	$t_{60}-t$, or Col. 6−Col. 2.	$t_{60}-t'$, or Col. 6−Col. 3.	$t_{60}-T$, or Col. 6−Col. 4.	T−(t_{20}−t). In Terms of Temperature, or Col. 4−Col. 9.	T−(t_{20}−t). In Terms of Tension corresponding to Temperatures.	T−(t_{60}−t). In Terms of Temperature, or Col. 4−Col. 10.	T−(t_{60}−t). In Terms of Tension corresponding to Temperatures.	P.	Wind.	Pressure of Vapour derived from the formulæ, $F' = f' - a\,(t_{60}-t')\frac{P-f'}{30}$.	Dew Point corresponding to F'.	Mortality Figures as given in "Government Gazette."	Mortality Figures, Average of Five previous Years corresponding to Col. 19.	Mortality Figures from 7th August 1894, Average of Five previous Years as given in "Government Gazette."	Mortality Figures from 2nd August 1887, Average of Five previous Years as given in "Government Gazette."	Mortality Figures, Daily Average derived from Col. 22.	Col. 8. × Col. 10.

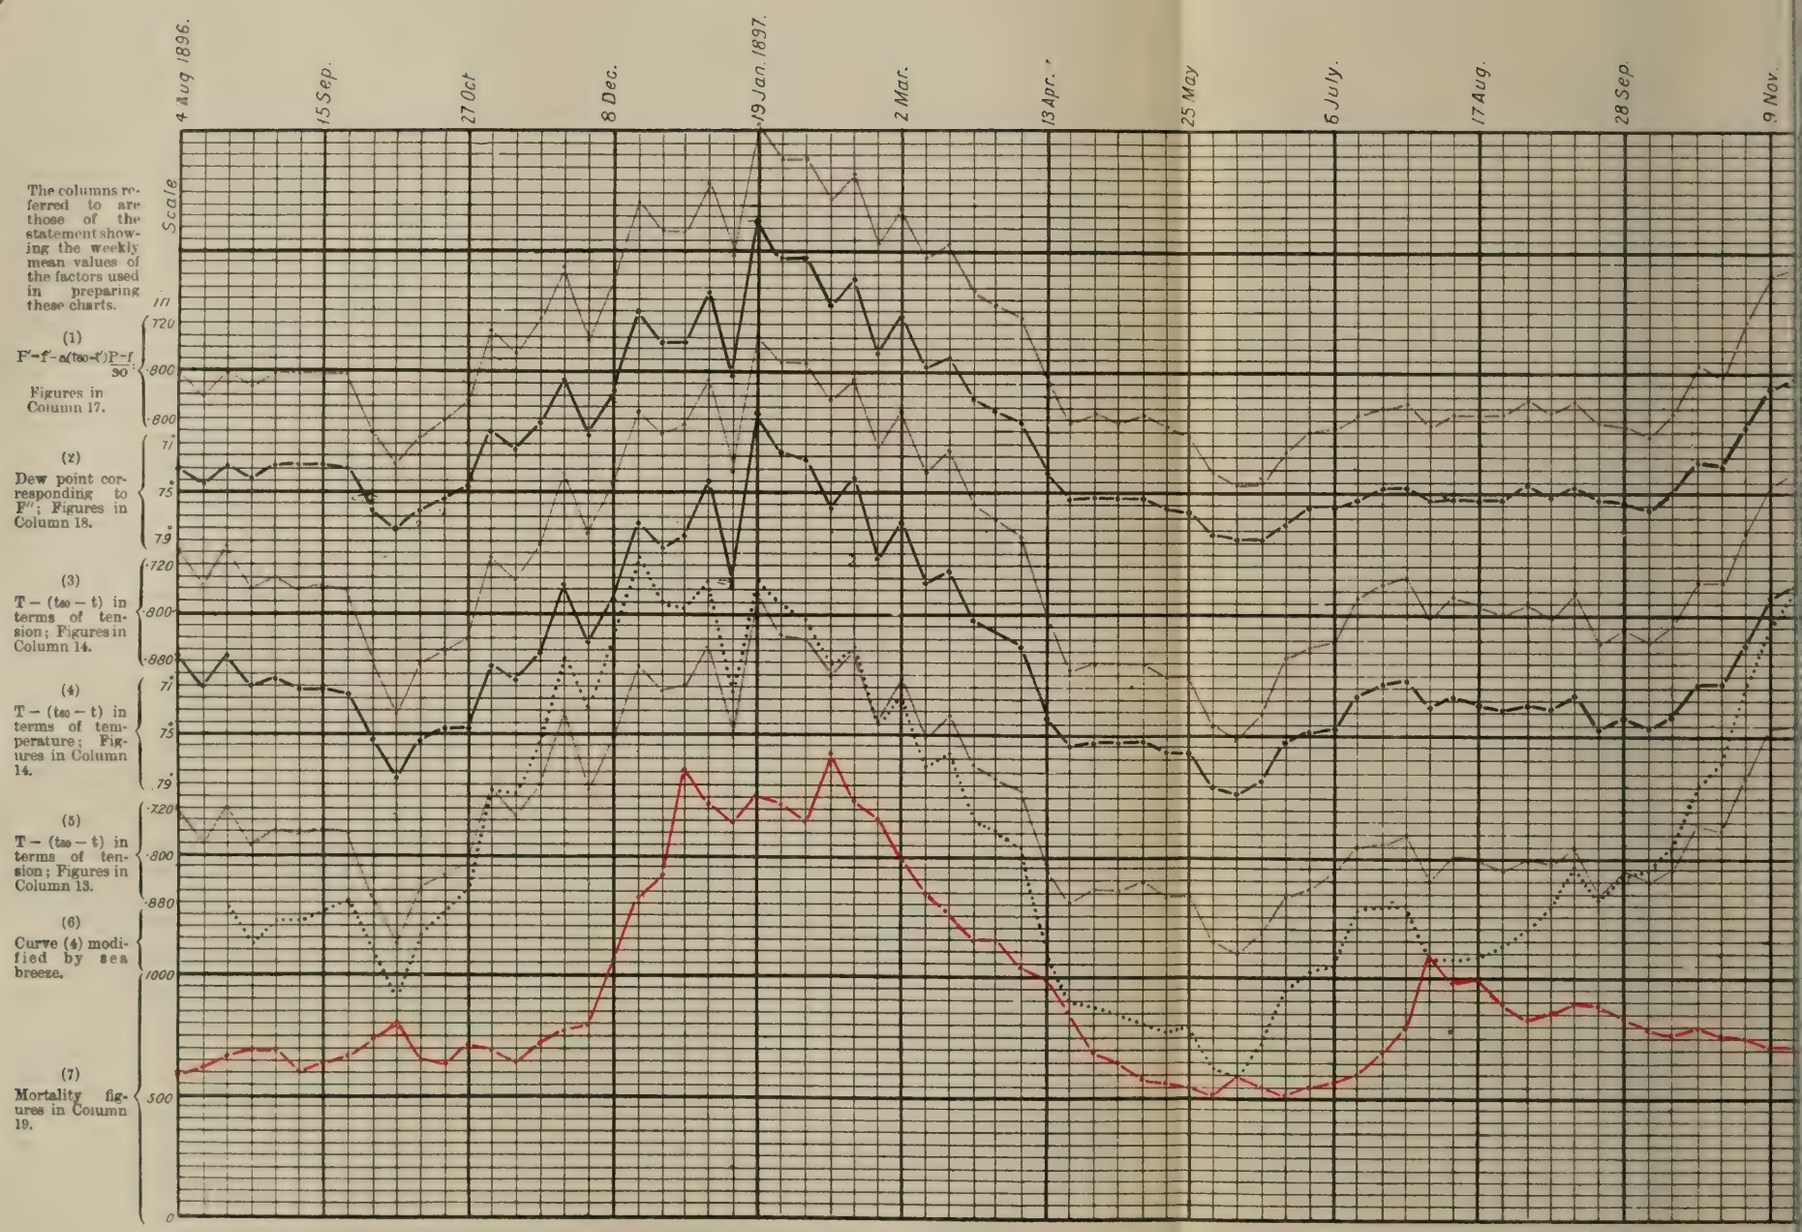
CHART A.—TRIAL CURVES. SHOWING THE RELATION BETV



The columns referred to are those of the statement showing the weekly mean values of the factors used in preparing these charts.

(1) $F'=f-a(t_{80}-t')\frac{P-f}{30}$ Figures in Column 17.

(z) Dew point corresponding to F′; Figures in Column 18.

(3) $T-(t_{80}-t)$ in terms of tension; Figures in Column 14.

(4) $T-(t_{80}-t)$ in terms of temperature; Figures in Column 14.

(5) $T-(t_{80}-t)$ in terms of tension; Figures in Column 13.

(6) Curve (4) modified by sea breeze.

(7) Mortality figures in Column 19.

EN PLAGUE AND METEOROLOGICAL CONDITIONS IN BOMBAY.

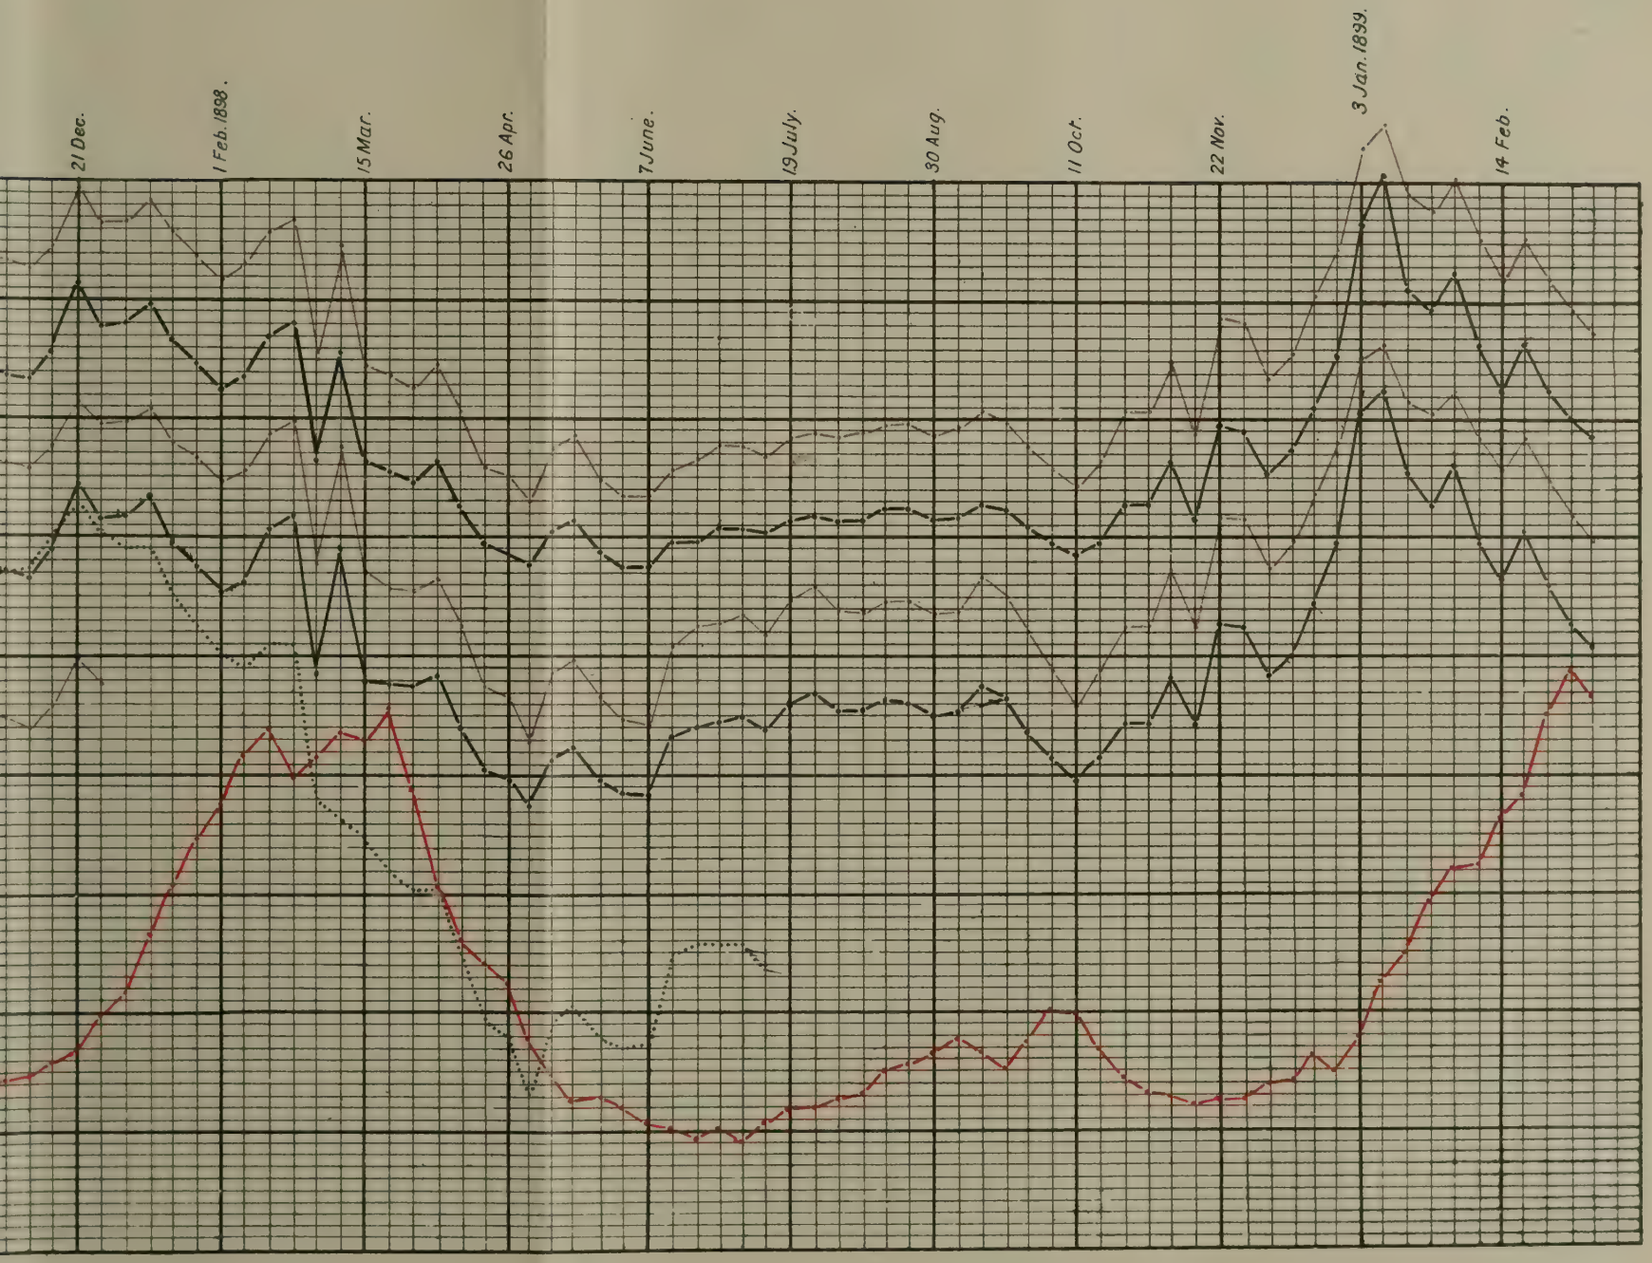


CHART B. SHOWING GROUND EVAPORATION A

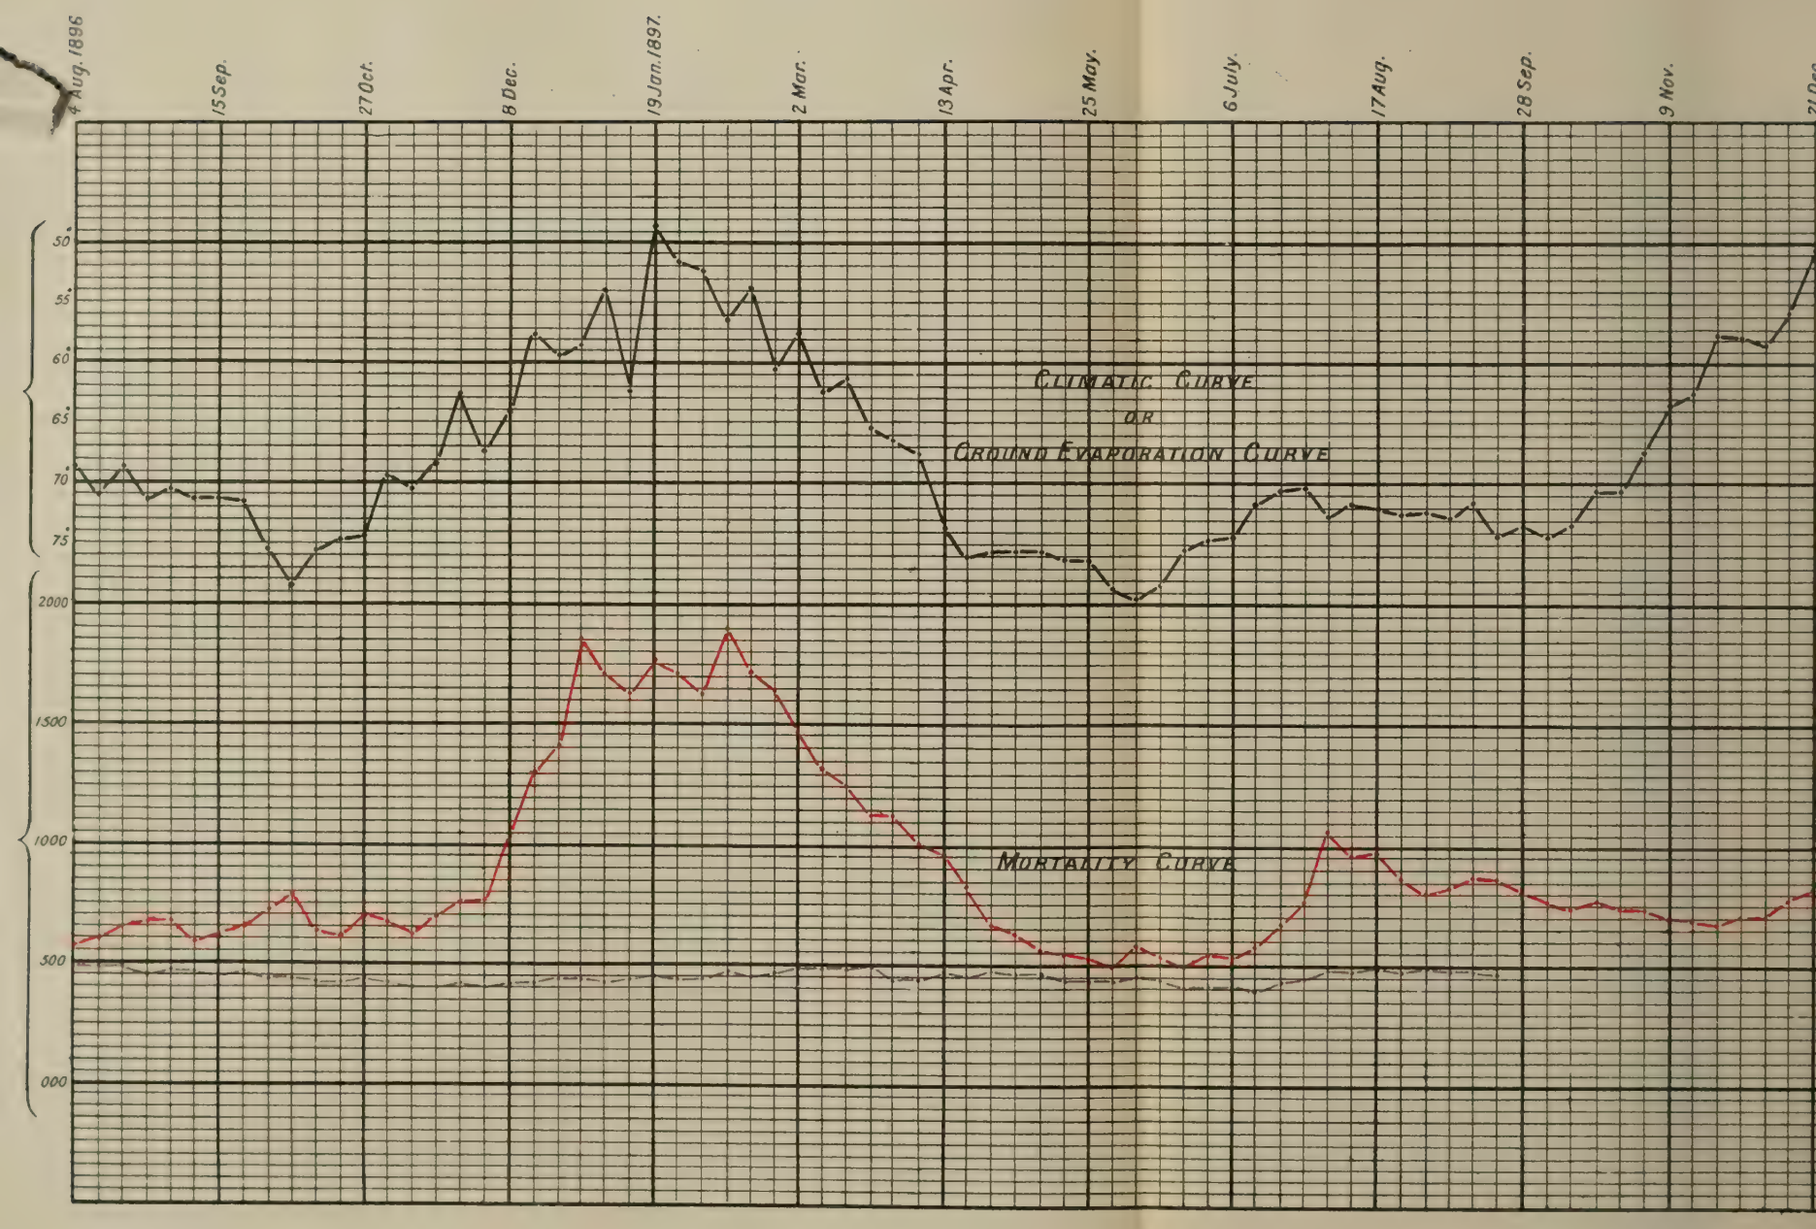

The mortality curve (in violet) represents the mean mortality of five

PLAGUE MORTALITY IN BOMBAY.

hy years from 1883 - 1887. when the mortality was a minimum.

Remarks on the Weather and Plague at Bombay, 1896–99,

by Alexander Buchan, LL.D., F.R.S.,

Secretary to the Meteorological Society for Scotland.

In the table appended to these remarks are set forth the mean weekly averages calculated from Professor Moos's figures for the 2¾ years, from August 1896 to March 1899, as follows:—

1. The average weekly number of deaths from all causes during the period dealt with. To this is added the average weekly number of deaths for the five years, 1893–97, when there was no plague; and the differences between these two sets of average weekly mortality which show, presumably, the average weekly mortality from the plague from its commencement to March 1899, embraced in Professor Moos's Report.
2. The mean weekly dry bulb and wet bulb at Bombay for the 2¾ years, these columns showing respectively the temperature of the air, and the temperature of the evaporation at Bombay.
3. The mean weekly relative humidity calculated from the dry and wet bulb means, this column showing the degree of humidity of the air at Bombay.
4. The mean weekly temperature of the soil at a depth of five feet, to which is added a column showing the weekly differences between this soil temperature and that of the air over the soil.
5. The mean weekly rainfall, in inches, at Bombay during the time.

These results are graphically represented on the diagram accompanying the tables.

I do not think it necessary to give any of the other meteorological data in illustration of the remarks, such as dew-point, barometric pressure, &c., as these do not appear to show any connection with the curve of mortality.

Weekly Mortality.—It will be seen that during the five years when there was no plague at Bombay, the weekly mortality varied only slightly during the year, the extremes being 475 deaths in the tenth week, and 392 deaths in the twenty-eighth week, the weekly average for the year being 439 deaths.

In striking contrast with this remarkable steadiness of the weekly mortality is the weekly mortality during the 2¾ years of the plague, the extremes now being 1,980 deaths on the tenth week of the year, and 474 deaths on the twenty-fifth week.

The annual march of the mortality through the weeks is shown by Diagram A. The result shows two maxima and two minima, the former, and by far the larger, maximum reaching its culmination from January to March, and the latter from August to October.

The larger maximum is practically coincident with the coldest weather of the year, and such weather particularly during the night, and, considered in connection with the habits, housing, and clothing of the population, may perhaps account for a part of this great mortality. The mortality falls steadily from the absolute maximum to the end of June, when the absolute minimum of the mortality occurs, all this taking place with a rising temperature which attains its maximum in June. From this time the humidity increases to the maximum which stretches over the next four months. This period covers the rainy season, and it is during this time that the secondary maximum mortality from plague occurs.

Thus, the two maxima occur respectively when the weather at Bombay is coldest and driest, and when the weather is wettest and still very warm.

A prominent feature of the mortality curve is that the curve of no single meteorological element taken by itself—such as temperature of air, B; humidity, C; temperature of soil, D; or rainfall, E—agrees with the mortality curve.

Such a curve of agreement, however, is obtained from the differences between the temperature of the soil at a depth of 5 feet, D, to which the daily changes of temperature do not penetrate, and the temperature of the air over the soil, F. To show this more impressively, the figures in the diagram A and F are both coloured black. A very important point in the relations of the two curves is that all the phases of F precede in time by a week or two the corresponding phases of A, just as in the case of London, where the commencement of hot or cold weather precedes by a week or two the increased mortality which results from these types of weather.

Since the temperature of the soil, at a depth to which the daily changes do not reach, is higher than the air over it, amounting to from 4° to 11° during the high mortality from plague, it follows that at these times the "*Grundluft*," or air in the soil, will rise out of the soil most readily and pass into the air, carrying with it the noxious impurities in the soil.

This connection between the curve of mortality and these temperatures' curve opens up a field of research to the physician and the bacteriologist, and the research is all the more likely to lead to good results when it is kept in mind that the principal maximum mortality of the year occurs when the weather is coldest and driest, and the secondary maximum when the weather is moistest and wettest, and the temperature very high.

Edinburgh, 2nd September 1899. (Signed) A. Buchan.

TABLE showing the MEAN WEEKLY MORTALITY, TEMPERATURE, HUMIDITY, and RAINFALL at BOMBAY, in Connection with the PLAGUE there.

Attached to Dr. Buchan's Note.

1705	Md. Ahmedkhan - - -	35	23.6.98	5	21.7.98	29.6.98	Recovered.

The number of dead rats or sick rats found during the attack was quite inappreciable. I should say that not more than half a dozen in all; one thing, however, is, I think, noteworthy, and that is, that as the plague increased in virulence in the Prison surroundings, the number of rats decreased, and *vice versâ*, and at the recrudescence of the plague they disappeared altogether, not a rat was to be seen for weeks, but about three months ago they commenced to return, and now the Prison is simply surrounded with them.

* (Serial No. 84; reg. No. 20) This case died in Jail from tubercle of lung, the symptoms of the disease set in rapidly after inoculation.

The following prisoners were not inoculated on the 9th of January, 1898:—Nos. 73, 26, 24, 165, 82, 132, 200, 85, 113, 20, and 198.

The 50 prisoners against whose names no dates are recorded in the last column were still in Jail on 25th February 1899, when this list was prepared.

A. M. KING,
Assistant Surgeon.

GEORGE WATERS, Lieut.-Colonel, I.M.S.
In Medical Charge, Her Majesty's House of Correction, Byculla.

APPENDIX No. LXI.

APPENDIX No. LXII.

REPORT
BY
KHAN BAHADUR N. H. CHOKSY
ON
CASES OF PLAGUE TREATED WITH PROFESSOR LUSTIG'S SERUM
AT THE
ARTHUR ROAD HOSPITAL, BOMBAY.

Arthur Road Hospital, Bombay,
3rd May 1899.

To the Municipal Commissioners, through the Special Medical Officer and the Executive Health Officer.

SIR,

I HAVE the honour to submit herewith the following report and return of cases treated with Professor Lustig's serum during April 1899:—

1. The number of cases treated was 39, of whom 21 died and 18 recovered, giving a mortality rate of 53·84 per cent. The mortality rate of cases not similarly treated was 77·51 per cent., thus showing a difference of 23·67 per cent. in favour of the former.

2. The cases were divided into the following series:—

Series.	Horse No.	Bleeding.	No. Treated.	No. Died.	No. Recovered.
VIII. (completed).	5	Second	16	10	6
IX.	Donkey	First	2	1	1
X.	3	Second	14	7	7
XI. (to be continued).	1	„	7	3	4
Total -	- -	- -	39	21	18

3. From a comparison of the returns for February, March, and April, it appears that each succeeding month the serum shows better results as it becomes stronger and more active. And considering that the present epidemic did not show any marked decline till about the middle of April, and that the individual cases do not even yet show any marked diminution in their virulence, in spite of the fact that the epidemic is steadily declining, the results so far achieved should be considered satisfactory. This is better illustrated by the following table, which compares the results during the period:—

Months, 1899.	Mortality Rate of Cases not treated with the Serum.	Mortality Rate of Cases treated with the Serum.	Difference in favour of Serum Cases.
February - -	79·16	70·58	8·58
March - -	79·48	66·21	13·27
April - -	77·51	53·84	23·67

4. The above table shows that whereas the mortality rate has varied very little amongst the cases not treated with the serum, and is not higher than the average rate of all the other hospitals, it shows a very appreciable improvement in those treated with it. And the improvement has steadily bettered from 8·58 per cent. to 23·67 per cent., a difference of over 15 per cent.

5. When all the series of cases are compared, two points are clearly brought out, viz.:—(1.) That the serum obtained from the second bleedings is more active than from the first, and (2) that the serum from the different horses shows different degrees of activity:—

Series.	Horse No.	Bleeding.	No. Treated.	No. Died.	No. Recovered.
I.	5	First	18	14	4
II.	2	„	11	8	3
III.	3	„	17	10	7
IV.	2	„	13	11	2
V.	1	„	17	12	5
VI.	4	„	47	30	17
VII.	6	„	13	8	5
VIII.	5	Second	22	14	8
IX.	Donkey	First	2	1	1
X.	3	Second	14	7	7
XI.	1	„	7	3	4
Total -	- -	- -	181	118	63

The above statement indicates that the results from the first and second bleedings were 68·38 per cent. and 55·81 per cent. respectively, thus clearly indicating a difference in greater activity of 12·57 per cent. from the latter. And as the serum gets stronger at each subsequent bleeding, it is to be expected that better results would be shown in the near future. The serum supplied from Florence last year also showed similar variations between the first and second bleedings.

The table demonstrates that different horses give serums of different activities, and this also materially corroborates the experience of last year, when it was observed that the different horses under experiment at Florence gave serum of different curative values.

6. Including the observations made last year, the total number of cases treated with Professor Lustig's serum now amounts to 349, and the following deductions have been drawn from the experience thus acquired:—

1. That the only known method of treatment that holds out any hope of reducing the high mortality from plague is that by Professor Lustig's curative serum.
2. That where the serum does not avert death, it considerably ameliorates the symptoms, and prolongs the life of the patient.
3. That the serum has, and cannot but have, a limited value in the treatment of the class of patients admitted into the Arthur Road Hospital; patients drawn from the lowest strata of society, badly housed, badly nourished, or half starved, the homeless, the friendless, and the vagrant, picked up from the streets and bye-lanes of the city, and brought to the hospital in a moribund or semi-moribund condition, and after the vital organs have become thoroughly disintegrated by saturation with the plague poison.
4. That if the mortality rate in such patients could be reduced by even 15 per cent., the results should be considered extremely satisfactory.
5. That the serum treatment has long since passed the experimental stage, and that its use should be freely encouraged, so as to collect data on the largest scale possible.
6. That with a view to test the full efficacy and value of the serum, it should be used extensively in early cases, and also in those that are allowed to be treated in their houses by private practitioners.
7. That the best method of using the serum in hospital practice is to exclude all moribund and all convalescent and semi-convalescent patients, and to treat the rest.
8. That if the method above indicated were not followed, it would lead to much unnecessary waste of serum, which could be better applied in more suitable cases.

9. That the statistical method is not the only method of judging of the efficacy of the serum, as it takes no cognisance of the effects in individual cases, and that clinical observation should not be totally ignored as it is of as much, if not more, value in determining its effects.
10. That if any statistical method has to be relied upon for purposes of comparison, it should be between the cases treated with and without serum after the moribund, the convalescent, and semi-convalescent have been excluded from each class.
11. That this method, even, is not free from objections, inasmuch as it takes no account of the individual differences in castes and races, sex, age, location of buboes, duration of illness at the time of treatment, the general condition of the patients, &c., &c., factors which considerably influence the mortality rate in plague, and which must, to a great extent, be similar, if not actually identical, in the two classes of cases taken for comparison.
12. That it is not generally possible to obtain such exact control cases, even if the admissions into the hospitals be very large, and that all deductions drawn from comparison of control cases that do not fulfil the above requirements are open to doubt and are, proportionately, of less relative value.
13. That in the absence of such exact control cases, the method suggested in paragraph 10 is the only feasible and practicable, and open to least errors, especially if a large number of observations are made, the larger the better.
14. That the treatment of every alternate case, as has been suggested, is liable to even greater objection than the method suggested in paragraph 10, as it would entail the waste of serum in moribund cases, cases that nothing short of a miracle could revive, as also its further waste upon convalescent and semi-convalescent patients who are already on the high road to recovery, and who require no further active treatment by drugs or by serum to complete their cure.

N. H. Choksy,
Medical Officer in Charge,
Arthur Road Hospital.

The following papers, viz., a Report by Captain Childe, I.M.S., on the treatment of plague cases in Bombay by Galeotti's serum, with lists of cases treated in the Mahratta Hospital, Bombay, and, from the 29th of January 1899 to the 27th March and in May 1899, in the Arthur Road Hospital, Bombay, have been forwarded to the Indian Plague Commission by the Government of Bombay.

REPORT

ON THE

TREATMENT OF PLAGUE IN BOMBAY BY Dr. GALEOTTI'S CURATIVE SERUM,

BY

Captain L. F. CHILDE, I.M.S.

Observations.—The total number of cases treated by Dr. Galeotti's serum, from February 2nd to March 27th, has been 148; of which 125 were treated at the Arthur Road Hospital, 12 were treated at the Marátha Hospital, and 11 were treated at their own houses.

By sex, these 148 persons consisted of 118 males and 30 females (11 being children); and

By caste, there were 117 Hindus, 18 Native Christians, 2 Pársis, and 4 Máhomedans.

With regard to duration of disease, it is found that—

30	were treated on the	1st	day of disease.
49	do.	2nd	do.
43	do.	3rd	do.
20	do.	4th	do.
4	do.	5th	do.
1	was do.	6th	do.
1	do.	7th	do
148			

so that 122 out of 148 patients were receiving the serum treatment on or before the 3rd day of plague.

Mortality.—Of the total 148 cases, 99 died, 43 recovered, and 6 are still under treatment.

Out of the 113 adult males, 78 died, 29 recovered, and 6 are under treatment.

Of the 24 adult females, 14 died, 10 recovered.

Of the 11 children, 7 died, 4 recovered.

Mortality by Caste.—Of the 117 Hindus, 80 died, 31 recovered, and 6 are under treatment.

Of the 18 Native Christians, 12 died, 6 recovered.

Of the 9 Pársis, 4 died, 5 recovered.

Of the 4 Máhomedans, 3 died, 1 recovered.

Percentage Mortality.—Of all the cases, the percentage of deaths to recoveries is 66·9, but if the 6 cases under treatment be excluded, the percentage mortality is 69·7.

By Sex.—Of the 113 adult males, the mortality is 69·1 per cent., but excluding the 6 cases under treatment, it amounts to 72·9 per cent.

Of the 24 adult females, the mortality is 58·3 per cent.

Of the 11 children, the mortality is 63·6 per cent.

By caste, the mortality is as follows:—

Hindus	68·4	per cent.
Máhomedans	75	do.
Native Christians	66·7	do.
Pársis	44·4	do.

1. *General Remarks.*—Selection of cases for treatment. In this enquiry an endeavour was made to confine the treatment to cases of average severity, that is to those who, on admission, seemed to have a reasonable chance of recovery; so that two classes of patients did not receive the serum, namely, those who were obviously moribund, and those whose symptoms were mild, and who were likely to recover, irrespective of treatment. It must be admitted that it is difficult to make a prognosis in any case of plague, as the most unexpected results occur; still, as far as could be judged from the symptoms on admission to hospital, the above selection of cases was made.

2. *Treatment in Addition to the Serum.*—In all cases at the Arthur Road Hospital a stimulant (rum) was given every two hours; and in cases showing symptoms of heart failure cardiac tonics were also administered, such as digitalis, strychnine, strophanthus, caffeine.

3. *Causes of Death.*—These were sudden heart failure, secondary pneumonia, bronchitis, œdema of the lungs, hæmorrhage, or exhaustion; in fact, death was due to the same causes as in plague patients not treated by the serum.

4. *Effects of the Serum Treatment.*—In many cases the temperature fell 1 or 2 degrees shortly after the injection of the serum, and with this fall there was a corresponding improvement in the patient's general condition; but this improvement was often only temporary, and would be observed after each subsequent injection; still, in those patients who died, the general course of the disease was steadily from bad to worse, and their symptoms were practically identical with those of plague patients treated in other ways.

5. *General Conclusions.*—From the evidence of this enquiry it cannot be said that Dr. Galeotti's serum treatment of plague shows any marked curative results; for of the 142 completed cases the mortality is 69·7 per cent., and the general death-rate of plague patients treated in a hospital is only a little higher. I am informed that this rate is 80 per cent., but have no means of verifying the statement; still, accepting this figure as correct, the most that can be claimed for Dr. Galeotti's treatment is a 10 per cent. reduction in mortality.

6. *Evidence of Early Cases.*—Of the 148 cases, 30 received the serum treatment on the first day of disease; and of these 30, 22 died and 8 recovered, so that in this series the death-rate was 73·3 per cent. Now it is an axiom in serum therapeutics that the earlier the treatment, the more favourable the prognosis; yet in this instance we find that the mortality of the patients treated on the first day is higher than that of all the patients who underwent the treatment; the respective figures being 73·3 and 69·7 per cent. This fact points to the same conclusion, namely, that treatment by Dr. Galeotti's serum has not much influence on the course of plague.

L. F. Childe, M.B., Captain, I.M.S.,
Acting First Physician, Sir J. J. Hospital.
Bombay, 4th April 1899.

—	18	—	10	—	—	—	—	—	—	—	—	Died 3.15 p.m., 31st January, 1899.	Temperature 106·4°, death from gradual heart failure; right cervical bubo.
20	—	—	—	—	—	—	—	—	—	—	—	Died 2.15 a.m., 31st January, 1899.	Injected on the 6th day; died 4 hours after injection; left inguinal and right femoral buboes.
—	15	—	15	—	15	—	—	—	—	—	—	Died 12 o'clock, 1st February, 1899.	Moribund; life kept up by stimulant injection; right inguinal bubo.
15	15	10	10	10	10	—	—	10	20	15	20	Recovered - -	Septic type; recovery without suppuration of bubo; right inguinal.
15	—	15	—	—	—	—	—	—	—	—	—	Died 10 p.m., 1st February, 1899.	Left axillary bubo; moribund; died 12 hours after admission.
10	10	5	5	5	10	10	10	5	5	5	5	Recovered - -	Septic type, profuse malaria, bubo left axillary, suppurated, good recovery, intestinal hæmorrhage.
—	15	15	15	15	15	10	15	—	15	15	15	Do. - - -	Bubo left axillary with infiltration; septic type; recovery with suppuration.
—	15	10	15	15	15	—	—	—	—	—	—	Died 7 a.m., 4th February, 1899.	Right axillary bubo; improvement and then relapse.
—	15	—	10	15	15	20	20	—	—	—	—	Died 6.50 p.m., 4th February, 1899.	Meningeal symptoms hæmatimesis; left inguinal bubo.
15	—	15	10	—	—	—	—	—	—	—	—	Died 9 p.m., 3rd February, 1899.	Multiple buboes; right axillary, right cervical infiltration.
—	15	—	—	—	—	—	—	—	—	—	—	Died 7 p.m., 3rd February, 1899.	Injected on the 2nd, died 2 hours after injection; right axillary and cervical buboes.
—	15	—	—	—	—	—	—	—	—	—	—	Died 12.15 p.m., 3rd February, 1899.	Left femoral, inguinal and iliac buboes; moribund; died 6 hours after injection.
—	15	18	10	15	15	—	—	—	—	—	—	Died 8 a.m., 5th February, 1899.	Semi-conscious on admission; right femoral inguinal and iliac buboes.
—	15	15	15	15	15	—	—	—	—	—	—	Died 9.15 p.m., 6th February, 1899.	Bubo, left inguinal; death from failure of heart.
—	20	15	20	20	20	15	15	—	—	—	—	Died 6.30 p.m., 12th February, 1899.	Buboes, left inguinal, femoral and iliac, right; lived for 8 days, death from œdema of lungs.
—	20	20	20	20	20	—	—	—	—	—	—	Died 9 p.m., 8th February, 1899.	Heart very feeble, very delirious, life prolonged by stimulant injections; right inguinal and iliac buboes.
10	10	—	—	—	—	—	—	—	—	—	—	Died 10 p.m., 6th February, 1899.	Tetanic injection stopped; right femoral bubo.
15	—	—	—	—	—	—	—	—	—	—	—	Died 12.50 noon, 3rd February, 1899.	Moribund; died 2 hours after injection; right femoral bubo.
—	20	20	20	20	15	15	15	15	—	—	—	Died 21st February, 1899.	Death from œdema of lung; right femoral bubo.
15	15	15	15	10	10	10	10	—	—	—	—	Recovered - -	Right axillary bubo; good recovery without suppuration of bubo.
—	15	15	15	—	—	—	—	—	—	—	—	Died 10.15 a.m., 5th February, 1899.	Unconscious; left femoral and iliac buboes; temperature 105°–106°; heart failure.
—	15	10	10	15	20	20	20	—	—	—	—	Died 10 a.m., 7th February, 1899.	Almost unconscious; left inguinal and axillary buboes; life prolonged by stimulant injections.
5	5	—	—	—	—	—	—	—	—	—	—	Died 6.45 a.m., 5th February, 1899.	Sudden failure of heart; right femoral bubo.
10	—	10	10	—	—	—	—	—	—	—	—	Died 8.30 p.m., 6th February, 1899.	Convulsions and œdema of lungs; right axillary bubo.
—	15	15	15	10	15	10	10	10	10	—	—	Recovered - -	Right femoral bubo; septic type; good recovery; bubo suppurated.
20	20	20	20	15	15	—	20	10	10	10	—	Do. - -	Right inguinal bubo; septic type; good recovery without suppuration.
15	15	15	—	—	—	—	—	—	—	—	—	Died 3.55, 7th February, 1899.	Sudden failure of the heart; left femoral and inguinal bubo.
—	20	20	20	—	—	—	—	—	—	—	—	Died 3 a.m., 8th February, 1899.	Heart failure; left femoral bubo.
—	20	20	15	15	20	20	15	—	—	—	—	Died 9.30 p.m., 17th February, 1899.	Died of exhaustion; right inguinal bubo.
—	20	20	15	—	—	—	—	—	—	—	—	Died 7.30 p.m., 6th February, 1899.	Right femoral and iliac, right axillary buboes.
—	20	20	20	20	20	10	—	10	10	10	—	Died, 23rd February, 1899.	Left femoral inguinal and iliac buboes; died of exhaustion from sloughing of iliac bubo.

elongs. This table, attached to Captain Childe's report, corresponds with tables submitted to the Municipal Commissioner, comprise only Series 1 2 3, 4, cases Nos. 1 to 6, 16 and 17 in Series 5, and Case No. 30 in Series 6 in Captain Childe's tables. published. References have been given to the Charts published in App. No. LXIII, where those Charts relate to cases entered

CHARTS RELATING TO THE PLAGUE IN KARAD IN 1897-8.

(See Question No 21088.)

Chart showing the entries into Karad Town through the Observation Camp and by means of "periodical examination," less those leaving the Town through the Observation Camp. It is not accurate as showing the actual entries into the Town, but shows very well the trend of the population. The red line shows the period when there were more departures from than entries into the Town.

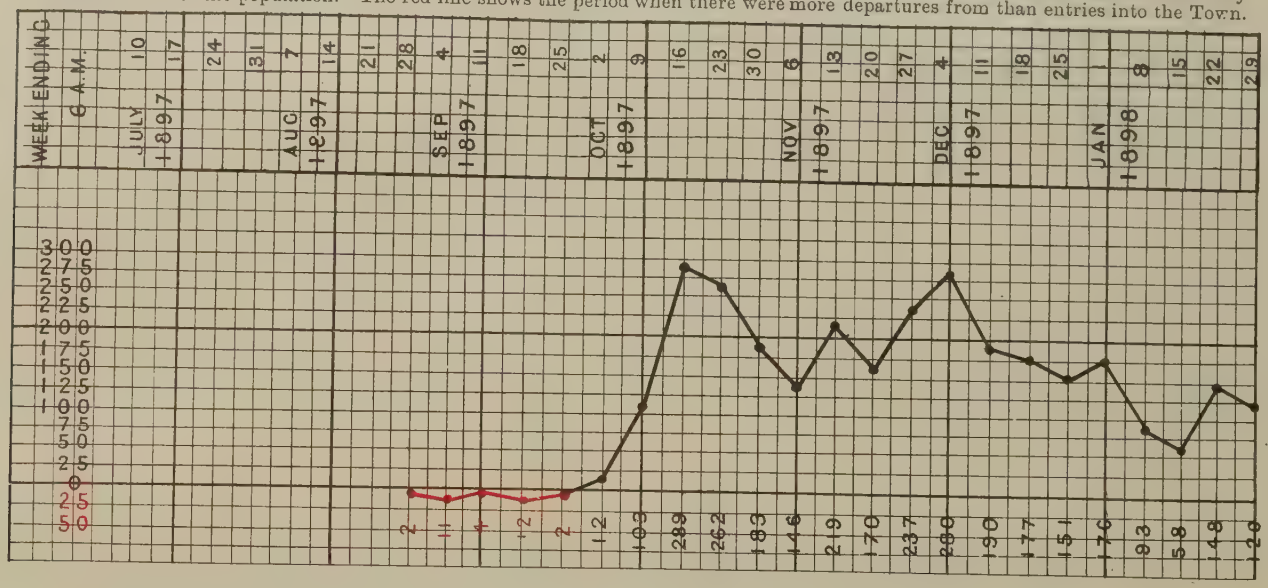

Chart shewing progress of Plague in Karad Town, 1897-98. Includes only the attacks and deaths in the Town proper. Attacks red, deaths black.

APPENDIX No. LXVIII.

REPORT by the PLAGUE COMMISSIONER, HYDERABAD, to the GOVERNMENT OF INDIA,

regarding the

DISSEMINATION of the INFECTION of PLAGUE through the Medium of RAW COTTON.

PLAGUE—HYDERABAD STATE.

No. 999 M., dated Camp Mandalgira, the 12th January 1899.

From A. H. STEVENS, Esq., Deputy Plague Commissioner, to Lieutenant-Colonel E. LAWRIE, M.B., I.M.S., Plague Commissioner, Hyderabad State.

I HAVE the honour to report that, from personal ervation in plague infected and adjacent areas, I e come to the conclusion that the infection of plague isseminated through the medium of raw cotton.

ly reasons for arriving at this conclusion are as ows:—

have reported the difficulties that have from time time been experienced in evacuating houses, and sequently in disinfecting them (by digging up and ning the floor surfaces by the kiln process) owing to verandahs and outer rooms (which are almost ariably the sleeping places in village houses) being cked up with bales of unpressed cotton (the usual e of each bale, which is sewn up in rough gunny th, is about 6 × 3 × 3). I have noticed these bales otton in almost all the Kopbal infected villages as l as, in a few instances, in Lingsugur, and in the ected villages round Sholapur. I also remember my istant Mr. Venkatesha Rao reporting the same state affairs last year at the infected village of Pallaskheda r the Khandesh frontier.

The danger of plague infection being propagated ough the medium of cotton bales was most forcibly pressed upon my mind a few days ago, when I saw ne hundreds of bales of cotton despatched by rail m Bannikop Station on the Southern Mahratta ilway. On inquiry, I found that this cotton had n brought the same evening from the infected age of Bannikop, which is only one mile from the lway station, and in which over 400 people have hin the past two months died of plague. I forthh rode to the village, which is being disinfected. I saw the last lot of bales of cotton belonging to the signment taken out of the verandahs of two houses which I had some weeks before seen plague corpses ng, as well as the sick suffering from plague. The es were loaded on carts, taken to the railway station, l lifted direct from the carts into closed cotton vans, interval that elapsed between the bales leaving the ected premises and being packed in the closed ton waggon was considerably under one hour. The ne was 4.30 p.m., when there was little or no sun to troy the bacillus or infection during transit; and I no reason why each bale of cotton thus sent should be a medium for spreading the disease into whatr city or town it is imported; whether taken to a ton press for pressing, or to a mill for manuturing, all the conditions surrounding it, and its ure treatment, would be favourable to the propaion of plague by means of the infection contained in bale.

At present, as far as I understand, very little is own as to the actual manner in which plague infecn is propagated, but I believe I have hit upon one y in which it may be, by means of the railway, seminated far and wide into the very centres of ies and towns supposed to be safeguarded and hedged und by the strictest quarantine and other plague gulations.

It is noteworthy how persistently plague has stuck the cotton manufacturing towns and the cotton procing districts, and no explanation of the reason of s has, I believe, been brought forward.

Possibly cotton itself may, under certain conditions, be a medium favourable for preserving the plague bacillus alive for a long time, and this may explain some of the hitherto unaccounted for outbreaks of plague at various places, the origin of which have never been traced out.

The subject is one that is, I think, worthy of scientific investigation, such as I am unable to bring to bear upon it, and is one that may be advisable for the Plague Commission to inquire into.

With reference to the case in point—the Bannikop cotton—you may ask why I permitted it to be exported? I am not aware that I have any legal power to stop it. The consignments of country produce from these districts are made in fulfilment of contracts with large mercantile firms such as Ralli Brothers and others, and any interference on my part might lead to a law suit. I shall, therefore, be much obliged if my legal powers in the direction of interfering with the cotton and other trades may be exactly defined for my future guidance.

No. 472, dated Hyderabad, the 25th January 1899.

From Lieutenant-Colonel E. LAWRIE, Plague Commissioner, Hyderabad, to the FIRST ASSISTANT RESIDENT, Hyderabad.

I HAVE the honour to enclose a copy of a letter from Mr. A. H. Stevens, Deputy Plague Commissioner, Hyderabad State, on the subject of the dissemination of the infection of plague through the medium of raw cotton.

On receipt of Mr. Stevens' letter, I telegraphed to him to forward specimens of the cotton he suspected to contain the infection to me for bacterioscopic examination: and specimens were accordingly received from him on the 22nd instant.

Cultures in sterilised broth were made from these specimens by Dr. Mullanah the same day. On the 23rd instant, the broth had become cloudy and contained a growth. Preparations from this growth showed a variety of organisms, among which a polar-stained bacillus, morphologically resembling the bacillus of plague, was prominent. At 2 o'clock p.m., that day three rabbits, which had been inoculated with a culture of the organisms found in Haffkine's fluid on the 28th of December 1898, and the 1st and 4th of January 1899, were inoculated with ½, 1, and 2 c.c. respectively of the broth culture made from the organisms in the suspected cotton. The temperature of the first rabbit rose rapidly to 105, and it died on the morning of the 25th instant, about 36 hours after the inoculation. *Post mortem* examination showed that it died of plague, and the plague bacillus was found in the glands, in the lungs, and in the spleen. A few were also found in the blood. A control experiment made with ordinary raw cotton bought in the bazar shows that it contains no organisms such as were found in the infected cotton.

The importance of Mr. Stevens' discovery—that the infection of plague can be disseminated through the medium of raw cotton—cannot be over-estimated, and I am of opinion that it ought to be communicated at once to the Government of India and to the Indian Plague Commission.

No. 11–C., dated Hyderabad Residency, the 27th January 1899.

From Sir TREVOR CHICHELE-PLOWDEN, K.C.S.I., Resident at Hyderabad, to the SECRETARY TO THE GOVERNMENT OF INDIA, Home Department.

I HAVE the honour to forward, for the information of the Government of India, a copy of a letter, No. 472, dated the 25th January 1899, from the Plague Commissioner, Hyderabad, with a copy of its enclosure, regarding the dissemination of the infection of plague through the medium of raw cotton.

No. 485, dated Calcutta, the 6th February, 189

From R. NATHAN, Esq., Under-Secretary to the Go ment of India, to the SECRETARY TO THE I PLAGUE COMMISSION.

I AM directed to forward, for the informati the Indian Plague Commissioners, a copy of a l from the Resident at Hyderabad, No. 11–C., dated 27th January, 1899, regarding the disseminatio the infection of plague through the medium of cotton.

APPENDIX No. LXIX.

MEMORANDUM ON EXPERIMENTS TO DETERMINE THE PROPHYLACTIC EFFECT OF HAFFKINE'S FLUID ON RABBITS,

Performed by Order of the Plague Commissioner, Hyderabad,

by

Lieut.-Colonel E. Lawrie, M.B., I.M.S., and Mr. Mullannah, M.B.

Summary.

Class A.

Animals protected with re-sterilised Haffkine's fluid.

Recovered after inoculation with plague	9
Died	1
Died from the protective	0
Total	10

Of the animals experimented on in Class A., two had one large dose of the protective (20 c.c.), one had two large doses (20 c.c. each), four had one small dose (2 c.c.), and two had two medium doses (6¼ c.c.). The rabbit that died had two small doses of the prophylactic of 1 c.c. each.

Class B.

Animals protected with contaminated Haffkine's fluid.

Recovered after inoculation with plague	20
Died	10
Died from the protective	8
Total	38

Of the animals experimented on in Class B., two of those that recovered had one large dose of the protective (20 c.c.), one had one small dose (2 c.c.), 15 had two large doses (20 c.c.), and two had two small doses (6¼ c.c.). Of those that died in this class, four had one small dose (1 to 6 c.c.), and six had two large doses (20 c.c.) of the protective. One animal that died of the effects of the protective alone died of plague.

It must be noted that for the purposes of the experiments the doses of both the prophylactic, and of the plague cultures, administered by inoculation were unusually large. This was especially the case with the inoculations with the contaminated fluid.

Remarks.

1. Haffkine's fluid is presumably a culture in peptone of the plague bacillus; the bacillus having been killed off the products remain.

2. The fluid is of uncertain strength. As received by us originally it was, without exception, contaminated with organisms of putrefaction. Latterly it has been much purer. It did not occur to us that a fluid sent out from a bacteriological laboratory for inoculation could be contaminated from inefficient or careless preparation or putting up, and we naturally supposed that the organisms we found in the fluid constituted part of its normal composition (one of us, Dr. Mullanah, dissents). The presence of the organisms in the fluid being adventitious or accidental they have no bearing on the question of the value of Haffkine's inoculation against plague, though it is of the last importance to insist on the necessity of preventing contamination of any kind from occurring in the fluid. It is probable that the opposition to vaccination in England is due to accidental contamination of the lymph ordinarily employed having given rise to occasional cases of septic intoxication which have been ascribed, by the ignorant public, to the vaccine lymph itself instead of to its impurities. In this way vaccination has been brought into such discredit that the Vaccination Acts of Great Britain have been practically repealed. There is very little doubt that in a similar manner injury has been done to the cause of Haffkine's inoculation against plague in India.

3. The effects of the contaminated fluid are two-fold. It produced:—

(*a*) Septic intoxication.

(*b*) The so called "reactionary" fever.

4. When employed by inoculation in rabbits—animals which are peculiarly resistant to ordinary septic processes, but are the best of all for experimental purposes with plague—it was found that large doses of the contaminated fluid protected against the effects of subsequent inoculation with plague. Small doses afforded little or no protection. But it was also found that eight animals died of the effects of the protective inoculation alone, while the protection against the effects of subsequent inoculation with plague was so limited that 33·4 °/₀ of the animals experimented upon died of plague.

5. The effects of the Haffkine fluid when resterilised are very different from the above. When employed experimentally in rabbits it was found that large doses are not always required. Moderate or even small doses afford adequate protection. No animals died of the protective inoculation alone, and the maximum of protection is afforded by the fluid against the effect of subsequent inoculation with plague.

6. The effects of inoculation of the sterilised fluid in rabbits, and also, as far as our limited experience goes, in man, are simple. It produces "reactionary" fever alone without, as a rule, any evil consequences. The question is, what is this "reactionary" fever due to? There can be little doubt that it is due to plague. (One of us, Mullanah, says it is due to the plague toxins.) Plague is a disease which shows itself in many forms. In its virulent forms it is highly infectious, in its mild aspects it is hardly infectious at all. To make inoculation universally acceptable what is now wanted is that Haffkine's fluid shall be made of uniform strength, so that with a minimum dose the reactionary fever shall be of known intensity and protective power, and not under any circumstances contagious.

APPENDIX No. LXX.

REPORT

ON A

Bacteriological Investigation in the Purity or otherwise of M. Haffkine's Plague Prevention Inoculation Fluid,

BY

Capt. C. A. Johnston, I.M.S.

From Captain C. A. Johnston, M.B., D.P.H., I.M.S., Medical Officer, 3rd Madras Lancers, to the President, Indian Plague Commission.

Sir, Secunderabad, 9th January 1899.

I have the honour to forward herewith as requested by the Indian Plague Commission, a report on a bacteriological investigation into the purity, or otherwise, of Haffkine's plague prevention inoculation fluid, accompanied with stained preparations of some of the organisms found.

The report has had to be drawn up rather prematurely this day, as I have to accompany my regiment out of Secunderabad on "Long reconnaissance," and shall be absent from the station for a week. I therefore regret that it cannot be so fully drawn up as it otherwise might have been.

Bacteriological Examination of Haffkine's Fluid.

Seven bottles of Haffkine's fluid, with the following numbers, taken at random from about 50 others, were examined:—

Brew No. 4168 (A) received at Hyderabad on 19th November 1898.
Brew No. 5324 received at Hyderabad on 16th December 1898.
Brew No. 5338 received at Hyderabad on 16th December 1898.
Brew No. 3962 received at Hyderabad on 20th October 1898.
Brew No. 4096 received at Hyderabad on 20th October 1898.
Brew No. 5349 received at Hyderabad on 16th December 1898.
Brew No. 5315 received at Hyderabad on 16th December 1898.

General Plan of Investigation.

Seven tubes of slant agar were inoculated with the above seven fluids, by allowing 10 to 15 minims of the fluid to flow in each case over the surface of the agar. The necks of the bottles and their mouths and corks were sterilized, and the corks were extracted with sterilized forceps, so as to allow no air or organisms to contaminate their contents and nullify the investigations. Two control tubes of the same preparation of agar were kept, into which tubes no Haffkine's fluid was poured, but whose cotton wool plugs were removed for a few seconds, to imitate the process of pouring fluid in, and then re-applied.

All these nine tubes were kept at the ordinary temperature of the room in a special glass case, and allowed to remain for one day, when they were examined, and it was found that there were growths of living organisms in every one of them except the controls:—Nos. 4168 (A), 5324, 3962, and 4096 showed luxuriant growths, the other three less, and No. 5315 showed least growth of all.

Details of the Experiments.

No. 1 Haffkine's Fluid: Brew No. 3962.

Ten to 15 minims poured over agar slant gave, after 24 hours, yellow white and ivory white discrete colonies all growing on the surface of the agar. There was no cloudiness, gas formation, or liquefaction. Microscopic examination revealed staphylococci in the white colonies, and bacilli and cocci mixed in the yellowish white colonies. The bacilli are short thick rods joined together in places forming chains, some short, others longer, and some are oval like cocci, and do not take the stain uniformly. The bacilli are actively motile and the threads lazily motile—decolorized by Gram. The first subculture in agar was made of the bacillary colonies (yellowish white), giving as a result yellowish white coalesced colonies, and a few isolated white colonies—these latter consisting of staphylococci and the former of a mixture of bacilli and cocci. A second subculture was therefore made giving also a mixture, but the cocci were fewer in number, so an attenuated third subculture was made with broth, and thrown into a petri dish which gave, in 24 hours a few faint bluish white colonies consisting of bacilli only. This was transferred as a fourth subculture on to agar slant tubes, which gave a pure growth of bacilli only—the growth consisting of a dirty white transparent film. Stained and hanging drop preparations of this film showed the following:—bacilli, fat, straight rods with rounded ends uniformly stained, some single, others joined end to end in pairs, freely motile, the single ones have a wriggling movement, the jointed ones an eel-like movement. The jointed ones appear to be the result of fission in older ones. The bacilli are all decolorized by Gram.

A rabbit (No. 126) was inoculated in the thigh with an emulsion in sterilized broth (4 c.c.) of these bacilli, and a fifth subculture in agar was made and kept. The rabbit (No. 126) had a slight fever (maximum 104·2) for two days, and is now well.

No. 2 Haffkine's Fluid: Brew No. 4096.

Fifteen minims of this was thrown over the surface of an agar slant tube and gave, after 24 hours, lemon yellow confluent colonies, white isolated colonies, and white moulds. No cloudiness of agar, nor liquefaction, nor odour were observed.

Microscopical examination revealed staphylococci in the yellow and white colonies—and mucor mucedo in the mould. No bacilli were present.

No. 3 Haffkine's Fluid: Brew No. 4168A.

Ten to 15 minims were poured over the surface of an agar slant tube, and within 24 hours there was a feathery greyish white growth—and after 48 hours a luxuriant growth of greyish white and yellow expansion. On using a magnifier the colonies are small, circular, and discrete, some being whitish and some yellowish white—at the bottom of the tube a distinct clump of ivory white colonies was seen, small, circular, and coalescing. No liquefaction of agar—all growing on surface.

Microscopic Examination.—By cover glass, stained with gentian violet, the microscope showed staphylococci, micrococci, diplococci, and some bacilli. Hanging drop preparation shows Brownian movement and very feeble motility.

1st Subculture.—A little of the culture was mixed with sterilized broth attenuated and spread over a petri dish of agar, and gave as a result, within 24 hours, separate lemon yellow colonies as well as small pearl-like discrete ones, and a clump of greyish white colonies. Cover glass preparations showed staphylococci in the lemon yellow colonies, cocci (mono. and diplo.) in the grey white clumps, and bacilli in the

pearly blue ones. A second subculture of these pearly blue colonies was made into agar slant tubes with the result that luxuriant growth took place in 24 hours, of small pearly blue colonies, which ccalesced. Cover slip and hanging drop preparations show a short fat coccoid bacillus, straight, very feebly motile, not of uniform thickness, not staining uniformly, with rounded ends, and no general true polar staining; decolorized by Gram's method, some of the bacilli appear like oval cocci.

A rabbit (No. 109) was inoculated with 3 c.c. of a mixture of these bacilli in sterilized broth into the subcutaneous tissue of the thigh, and as a result had slight fever—maximum temperature 103·6° for two days —no other signs of illness, and is now quite well.

A third subculture of the pearly blue colonies of the first subculture (petri dish) was made into agar slant and left for three days. When examined the same pearly blue coalesced colonies were seen, which on microscopic examination showed fields of cocco-bacilli which do not stain uniformly and are very feebly motile. A rabbit (No. 110) was inoculated in the thigh with 4 c.c. of this subculture mixed with sterilized broth, and had a rise of temperature to 105·2° for a day, then lysis to normal.

No. 4. Haffkine's Fluid: Brew No. 5315.

Ten to 15 minims thrown over agar slant gave within 48 hours a faint growth of isolated clear colonies —which on microscopic examination revealed staphylococci. No bacilli were found. Rabbits (Nos. 122, 123, and 124) were inoculated subcutaneously with this fluid, re-sterilized by fractional method to 55° C. for one hour for three consecutive days and gave with No. 122 a maximum temperature of 104·6° the same evening, and fever the following two days to 104·2°, then fell to normal. Rabbit No. 123 gave 105° same day, next day 106°, then lysis to normal. No. 124 gave 105° same evening and 105° next day, then lysis to normal. A rabbit No. 128 was inoculated with the same quantity of the same fluid unsterilized, and gave 104° the same evening and 104·4° next day.

These Haffkinized rabbits are to be tested as regards their immunity against an inoculation of plague.

No. 5. Haffkine's Fluid: Brew No. 5324.

Ten to 15 minims of this fluid were thrown over the surface of an agar slant tube. Within 24 hours it showed a thick luxuriant growth of greyish white colonies, some the size of a small pin's head; in other parts of the tube a whitish film. All the colonies are growing on the surface of the agar, without liquefaction or odour. Microscopic examination of these colonies by stained cover glass and hanging drop preparations show staphylococci and long bacilli, varying in length, with rounded ends, and straight rods. Some of the rods show swelling in the middle and do not stain uniformly. Hanging drop preparation shows these bulgings very distinctly and the bacilli are feebly motile. The bacilli are decolorized by Gram's method, but the bulging portion retains a little of the stain. They were mainly found in the whitish films of the culture, so the first subculture from this film was made on an agar slant tube which showed a luxuriant growth of whitish expansion as well as a yellow expansion. On microscopical examination these are found to consist of bacilli as well as cocci, so an attenuated second subculture mixed with sterilixed broth was thrown on to a petri dish. This showed three distinct forms of growth—a yellow brain-like expansion consisting mainly of staphylococci, a white brain-like expansion consisting mainly of cocci, and isolated grey white colonies consisting mainly of bacilli. A third subculture was therefore made of these isolated grey white colonies on to agar slant tubes. This third subculture shows a pure growth of bacilli which are straight rods, short and fat, somewhat like oval cocci, most of them non-motile, occasionally some of them, joined end to end, show motility.

[N.B.—A subculture of this has been sent to the Plague Commission.]

Rabbit No. 119 was inoculated with 4 c.c. of this third subculture in sterilized broth into the thigh. It gave a rise of temperature to 105° F. for one day and the temperature is 104° F. now.

A subculture was made of the yellow brain-like colonies of staphylococci from the second subculture of the petri dish to obtain a pure growth of the organism, and rabbit No. 121 was inoculated in the ear with 1 c.c. of the growth in sterilized broth, giving as a result pyrexia to 104° F. with local œdema, swelling, and congestion, and later an abscess and ulceration.

No. 6. Haffkine's Fluid: Brew No. 5338.

Ten to 15 minims of the fluid were poured over the surface of an agar slant tube, and after 48 hours a growth appeared as a thin dewy veil, with a few isolated colonies like dewdrops, and a dozen or so of raised round whitish colonies about the size of a small pin's head. No clouding or liquefaction or odour of agar.

Cover glass preparations (hanging drop and stained) were made and showed from the dewy veil and dew-drop colonies mainly cocci, while that from the white colonies showed bacilli.

The bacilli were short rods with rounded ends, in length about half the diameter of a blood corpuscle, some are in chains and a few are smaller like oval cocci—they stain fairly uniformly, but are decolorized by Gram's method. They have a very feeble movement in hanging drop—some are motionless. A first subculture of these whitish colonies was made on agar slant giving a fairly luxuriant growth of a yellowish white expansion which shows a mixture of staphylococci and bacilli. A further attenuation by a second subculture (mixed with sterilized broth) was made on a petri dish. The petri dish gave within 36 hours bluish white colonies containing long chains of bacilli—which were at once transferred by a third subculture on to an agar slant tube—which gave a growth of yellowish white colonies consisting only of bacilli. These bacilli varied in size, some were small and coccoid, others were in length about half the diameter of a blood corpuscle, and many were seen joined end to end (chiefly in pairs) giving short chains—their ends were rounded and they were rod shaped—showing feeble eel-like movements. A fourth subculture of this was made in agar slant and the remainder of the third subculture was mixed with 4 c.c. of sterilized broth and injected into the flank of a healthy rabbit (No. 120) on the 1st of January. Early on the morning of the 3rd January, within three days of inoculation, the rabbit died—the signs previous to death were firstly rise of temperature to 103·4°, then a sudden fall to sub-normal with giddiness and slight tremors; no diarrhœa. A *post mortem* examination was held the same morning with the following results:—

On reflecting the skin from the abdomen the blood in the vessels was seen to be very dark in colour and fluid, with patches of hæmorrhages on the subcutaneous surface of the abdomen and thorax. No enlarged glands were present. *Thoracic organs*—fluid in the pericardium—venous engorgement of the heart—lungs normal in appearance—heart blood dark and fluid. *Abdomen*—petechial hæmorrhages in abdominal wall. Large intestines very dark green in colour—spleen not enlarged but very dark. In the regions of the gall bladder, the liver, and adjacent surface of the stomach (which is distended with food) there is bile staining, the kidneys are highly congested and very dark in colour. Agar slant tubes were inoculated with a drop of the heart's blood, peritoneal fluid, spleen blood, and pulp—one pure agar slant tube being kept as control.

The blood, spleen, liver, and peritoneal fluid of the cadaver were examined microscopically, and bacilli were found in all in abundance, except the peritoneal fluid. The bacilli in all appear to stain uniformly (one or two in a field show polar staining) varying in length, but generally the length of half the diameter of a blood corpuscle, rod shaped, with rounded ends, some smaller and more oval and some joined end to end, giving a fission-like appearance. These bacilli are very similar morphologically to the bacilli in the subculture that was used for inoculation.

A fifth subculture was made from the fourth subculture, and another rabbit was inoculated.

Rabbit (No. 125) was inoculated with 4 c.c. of an emulsion of this subculture in sterilized broth, and had a temperature of 104·4 for one day and then lysis to normal.

The cultures in the agar tubes of the blood, &c., of rabbit No. 120, all show luxuriant bacillian growths except the control which shows none. These bacilli are found to be decolorized by Gram's method. The

growth appears to be of the following character:—greyish colonies, the size of pin's heads, circular, coalescing to form a greyish layer—that from the blood shows other kind of colonies raised small circular pearl-like rising above the greyish layer. The growth from the peritoneal fluid seems the purest. On microscopic examination of these growths, the one from the blood shows bacilli, some long rods, rounded ends, which are motile—others smaller, somewhat oval in form, which are not so motile; all show irregular staining, and are thicker at the ends than in the centre. The growth from the peritoneal fluid gave small rod-shaped bacilli, with rounded ends; and oval bacilli which are very feebly motile and do not stain uniformly. When treated first with alcohol and then stained they show polar staining. The culture from the liver shows two forms of bacilli, one set are polar stained, and the other, a longer rod, do not stain at poles. These bacilli are similar morphologically to some of the bacilli found in the subculture that was inoculated into the rabbit, and their culture growths are almost identical. These growths are to be further tested by inoculation into other rabbits, rats, fowls, and pigeons. A subculture of the culture from the rabbit's blood, when put into sterilized broth, made the broth cloudy and colonies fell to the bottom as a grey mass. Rabbit No. 125 had a rise of temperature to 104·5 the day following inoculation, and it is now falling towards normal.

A rabbit (No. 129) was inoculated with a subculture made from the peritoneal fluid of rabbit No. 120 that died, and gave a rise of temperature next day to 106·4°.

A pigeon was inoculated with a subculture of peritoneal fluid of rabbit No. 120 but only gave a rise of temperature to about one degree.

Two fowls were also inoculated subcutaneously and by injection into the mouth of subculture of peritoneal fluid and spleen of rabbit No. 120, but no pathogenic results followed.

The efficacy of re-sterilizing (by fractional method) and inoculation of this brew of Haffkine's fluid was tried on the following rabbits:—

Rabbit No. 111 was inoculated subcutaneously with 20 c.c. of the unsterilized fluid and showed a temperature of 106° (maximum) the second day, then lysis to normal, fever lasting four days. Rabbit No. 125 inoculated with the same quantity of re-sterilized H. F. 5338, subcutaneously, showed temperature of 104·8 (maximum) for a day.

No. 7. Haffkine's Fluid, No. 5349.

Ten minutes of this fluid thrown over agar slant gave within forty-eight hours isolated greyish white colonies and a whitish scum over the agar—no liquefaction or odour—later a few isolated white colonies appeared.

Microscope revealed only micrococci and staphylococci in the isolated white colonies. No bacilli were found.

Conclusions arrived at as the Result of the Experiments up to Date.

The samples of Haffkine's fluid examined bacteriologically all show contamination with living micro-organisms; in some cases—Nos. 5315, 5349 and 4096—the contamination seems to be with cocci alone, in the others, with a mixture of cocci and bacilli. Although the samples taken show the above contamination, other bottles of the same brew show contamination with other forms of micro-organisms. As far as the investigations have gone it will be seen that the micro-organisms isolated from the fluids are many of them distinctly pathogenic, some more virulently so than others, in one case (No. 5338) the microbe was so pathogenic as to cause death (*vide* rabbit 120). Rabbit No. 121 shows the effect of the contamination with cocci, which was the staphylococcus aureus, producing local disease (abscess and ulceration) and a pyæmia. If the temperature charts of the inoculations with one of the brews and the organisms isolated from that brew be compared, it will be seen that the inoculation with the fluid, as received from Bombay, gives a greater rise of temperature in most cases than the pyrexia produced by the isolated organisms; therefore, if the living organisms were extracted from the fluid before inoculation, a lower temperature ought to be the result of inoculating such a fluid. This idea seems to be confirmed when the temperature charts of rabbits 101 and 105 are compared. No. 101 is the result of inoculation of Haffkine's fluid No. 4168, giving a rise of temperature to 106°, followed by death; whereas No. 105 shows the result of inoculation of the same of Haffkine's fluid re-sterilized giving a resulting temperature of 104·5 as the maximum and, instead of death, recovery. This is one example of the effect of re-sterilizing Haffkine's fluid, but others are now being carried out. It would appear, therefore, that re-sterilizing does away with a severe form of septic fever and complications which arise from the contaminating organisms; but the question whether this re-sterilizing destroys the efficacy of the original Haffkine's fluid remains to be considered, this is also being done—*vide* temperature chart of rabbit No. 105 (Haffkinized with brew No. 4168). One c.c. of plague culture was inoculated on the 1st January, giving a slight fever only, whereas the control rabbit No. 115, inoculated on the same day with the same dose of the same culture, gave a rise of temperature to 107 and death. The re-sterilized Haffkine's fluid was tested as regards the presence of any living organisms at the same time as inoculation was done, but no living organisms were found to grow on the agar tube. Temperature charts of rabbits Nos. 122, 123, 124, 128 and 130 can be compared also, with regard to the question of re-sterilizing, but it ought to be borne in mind that this brew of Haffkine's fluid showed only slight contamination of cocci.

The following deductions may be drawn from the experiments that have been done so far:—

1stly, that in bottling the Haffkine's fluid from the retorts sufficient care does not seem to have been exercised in preventing contamination.

2ndly, allowing that same contamination is unavoidable, due to the enormous out-turn of fluid necessary to meet the demand, all the bottles on being filled and before being sent away should be re-sterilized to 60° C. for an hour, and the corks should be replaced by proper fitting glass stoppers. This probably would not destroy the chemical products of putrefaction. If this were done, and if it was proved that re-sterilizing does not injure the protective influence of the inoculation fluid, then I feel sure there would be less number of cases of septic poisoning among the inoculated subjects, for the fluid which is received now from Bombay is undoubtedly a "putrescent organic liquid," as stated before the Commission by the Plague Commissioner, Hyderabad.

Further investigations and experiments with reference to the inoculation fluids and their isolated living organisms are being carried out by the authorities in charge of the laboratory in Hyderabad in continuation of the above work, and if so required, a further report at a later date can be furnished by them.

My thanks are due to Lieut.-Col. E. Lawrie, I.M.S., for allowing me to use the laboratory; and to his staff for their kind assistance during the above work.

PLAGUE—HYDERABAD STATE.

INVESTIGATIONS TABULATED.

Bacterioscopic Examination of Haffkine's Fluid.

No. 1.

Agar slant.
+
H. F. No. 4168 A.

Luxuriant growth, a mixture of cocci and bacilli.

1st subculture.
Attenuated in broth; and a petri dish inoculated.

3 separate colonies.
A. Lemon yellow=staphylococci.
B. Grey white =cocci {mono— diplo—
C. Pearly blue =bacilli.

C

2nd Subculture agar slant.
One day's growth.

Bacilli, pure growth of pearly blue circular colonies coalesced.
Bacilli, short fat (cocco-bacilli) feebly motile.

Rabbit No. 109 was inoculated with 3 c.c. of this growth mixed with broth.
Result, fever slight (103·6° max.) for 3 days—now alive and well.

3rd Subculture agar slant.
Three days' growth.

Bacilli, pure growth, pearly white coalesced colonies, mainly cocco-bacilli.

Rabbit No. 110 inoculated. Result, fever 4 days max. temp. 105·2°, now alive and well.

No. 2.

Agar slant.
+
H. F. No. 5324.

Luxuriant growth of Staphylococci and bacilli.
1st subculture.

Attenuated by subculture in agar slant.

2nd subculture with broth (control of broth, done 3 Jan. 1899.)
Attenuation on to petri dish.

Three kinds of growth.
A. Yellow brain-like growth =cocci.
B. White do. do. =cocci.
C. Isolated grey-white colonies=bacilli.

C. Baccilli.

3rd Subculture into agar slant.
One day's growth.

Luxuriant pure growth of whitish grey film of bacilli.
Bacilli=short fat coccus-shaped, spore formation seen, motile at times, but chiefly non-motile.

(A special subculture of this was sent to the Plague Commission.)

Rabbit No. 119 inoculated with 4 c.c. of this pure subculture:
Result, fever, max. temp. 105°.

A. and B. Cocci.

Subculture in agar of pure staphylococci.

Rabbit's ear (121) inoculated with above, gave local abscess and ulceration.

No. 3.

Agar slant.
+
H. F. No. 5338.

Growth, mixture of cocci and bacilli.

Subculture in agar slant.

Luxuriant growth of cocci and bacilli.

Attenuated 2nd subculture in petri dish.

Yellow and white colonies of staphylococci.
Blue white colonies of bacilli.
Bacilli=irregular size, some thin, others thick, jointed and oval (motile).

* A subculture (4th) kept, and a rabbit No. 120 inoculated with 4 c.c. of culture in broth.

Death within 60 hours, temp. sub-normal.

Cultures in agar were made of spleen liver and peritoneal fluid of this rabbit, giving growth of bacilli similar to the bacilli in the subculture.

* The subculture shows thickish bacilli motile growing by fission

No. 4.

Agar slant.
+
H. F. No. 3962.

Luxuriant growth, mixture of cocci and bacilli; cocci=mono, diplo, and staphylococci.

Subculture in agar slant.

A. Yellow coalesced colonies=bacilli and cocci.

B. White isolated colonies =staphylococci

2nd Subculture in agar.

Bacilli chiefly, also a few cocci.

3rd. Attentuated subculture with broth on to petri dish—shows gossamer veil expansion over which a thick yellow white expansion is present.

4th. Subculture on agar slant gives luxuriant growth of yellow white colonies of bacilli similar morphologically to bacilli from 5338.

Subculture on agar slant of liquid yellowish expansion.

Subculture on agar slant.

Rabit No. 126 inoculated with 4 c.c. of bacilli subcutaneously, result, slight fever, now well.

No. 5.

Agar slant.
+
H. F. No. 4096.

Luxuriant growth of—
Lemon yellow colonies=Staphylococci.
White =Staphylococci.
Moulds whitish =Mucor mucedo.
No bacilli found.

No. 6.

Agar slant.
+
H. F. No. 5349.

Growth of isolated grey white colonies of micro-cocci only.
One or two white isolated colonies of staphylococci.

No. 7.

Agar slant.
+
H. F. No. 5315.

Faint growth of clear hyaline-like colonies of staphylococci.
No bacilli.

APPENDIX No. LXXVI.

NOTES ON THE TRAFFIC

between BOMBAY and MADAGASCAR

with special Reference

to the OUTBREAK of PLAGUE in TAMATAVE.

I. The Island of Madagascar, situate off the East Coast of Africa, forms the Eastern boundary of the Mozambique Channel. At the northern extremity of the Island is situate Dioga Saurez, the nearest port to Bombay, and much further down its eastern coast, the Port of Tamatave. On the northern half of the western face of the Island are situated Majunga and Nossi Bé: and between these latter and the Mozambique and Zanzibar portion of the opposing African shore the Islands of Mayotta and Comoro which, like Madagascar, belong to the French. All these places have at one time or other been called at by vessels leaving Bombay, and will be referred to again in what follows.

II. It is important to note that the minimum duration of the voyage from Bombay to the nearest port in Madagascar, viz., Dioga Saurez, for the class of steamers that run in that direction, is 15 or 16 days, and, for country craft, under the most favourable conditions of wind and weather, a month.

III. The outbreak of plague at Tamatave, and the subsequent statement of Dr. Proust that it had been proved that the disease had been carried to the Island, not by native craft, but by a ship laden with rice from Bombay, led to a careful investigation, having for its object the drawing up of a precise statement of the nature and amount of traffic, if any, between this port and Madagascar. The lines on which this investigation were carried out were as follows:—

Carefully kept registers of all ships leaving Bombay were scrutinised, and those leaving, not only for Madagascar, but for all Islands in the Indian Ocean lying west of India, and for all ports on the African coast were carefully tabulated. Such of the official logs of these ships as were available were then carefully examined, and the owners or agents of all ships in the list were interviewed.

IV. The information obtained was as follows:—

(1.) STEAMERS.

(*a.*) The British India Steam Navigation Company have not despatched any vessel, directly or indirectly, to any port in Madagascar probably for the last 10 and certainly for the last six years; nor have they booked cargo or passengers for trans-shipment to vessels bound for any port in the French Colony. They frequently send cargo to Zanzibar, and it may be that Zanzibar merchants may, and probably do, send portions of it on to Malagise ports, but the connection is a very indirect one indeed, the cargo having first to be landed and lie for some time in stores before being reshipped.

(*b.*) The German East Africa Company's steamers ply between Bombay and the East Coast of Africa, others of their vessels run up and down the African coast. The former never by any chance call at Bourbon, Mauritius, or Madagascar. The latter do call at Malagise ports. The Company have never sent either passengers or cargo from Bombay for trans-shipment on to their African steamers for Madagascar.

(*c.*) The Persian Steam Navigation Company have had no ships running to Madagascar since the end of 1897. Prior to this date (end of 1897) they did despatch an occasional vessel with cargo and passengers from Bombay and had intended to keep up a regular traffic with the Island, but a heavy tax on British borne goods, especially rice, and a heavy annual poll-tax on British subjects, natives of India, for the privilege of living in the Colony imposed by the French Government, has completely choked off the trade. The last of these vessels that had called at Madagascar was the s.s. *Mohammadi*. She left Bombay on the 9th of August 1897 with 691 passengers and a cargo composed largely of rice; ran direct to Delagoa Bay, where she discharged the greater number of her passengers and a portion of her cargo, and then proceeded to Madagascar, where she discharged the remainder of her passengers (no more than 50 in all (chief officer's statement)) and the following quantities of rice:—

Majunga	about	600 bags.
Nossi Bé	,,	800 ,,
Dioga Saurez	,,	2,900 ,,
Tamatave	,,	300 ,,

On this voyage the official log-book shows but one case of sickness, that of a native cook who was certified by the ship's surgeon to have died of "paralysis." This death took place between Dioga Saurez and Tamatave, 41 days after leaving Bombay, and after an illness of 30 days.

(*d.*) Mr. Haji Kasim has had steamers running from Calcutta, False Point, Balasore and other ports on the east coast of India to Bourbon, and perhaps Mauritius. These steamers may have been chartered from these places for Madagascar, but he is unable to give the details without reference to his agents on the other side of India. During the whole of 1898 and 1899 up to date, he has not sent any steamers from Bombay or any port on the west coast of India, directly or indirectly, to any port in Madagascar; nor has he, *at any time*, sent passengers or cargo to the Colony. During 1897 some of his Bombay ships did go to Madagascar but all these were chartered from Mauritius, left the Island in ballast and returned with bullocks. These steamers may have on rare occasions carried cargo to Madagascar, but this was Mauritius and not Indian cargo. The cessation of traffic with Madagascar, he stated, was due to the extraordinary high rate of duty charged on goods carried under the British flag.

(2.) COUNTRY CRAFT.

The pre-monsoon country craft traffic for 1898 began with a departure on January 8th and ended with one on the 7th of March. Between these two dates 17 vessels left Bombay for various ports in Madagascar, but none of these were bound for Tamatave. So that if they did ultimately go to that port they must have done so in the coasting trade of the Island. It is important to note here that Dr. Proust states that it has been distinctly proved that the plague was not carried to Madagascar by these vessels.

The post-monsoon traffic of 1898 opened with a departure on the 12th of December. From this date till the end of the year five vessels took out their port clearances and bills of health for Madagascar. Here again, not only were none of these vessels bound for Tamatave, but, to quote from a letter from the French Consul at Bombay, they would have arrived at their destinations after Tamatave was declared an infected port.

The following are precise details of this traffic:—

PRE-MONSOON.

ates.	Name of Ship.	Port bound for.
898.		
n. 8	Batel Sawai	Nossi Bé.
„ 8	Bugla Sahula	Mayotta.
„ 15	Gunja Fatch Salamat	Nossi Bé.
„ 15	„ Ali Madat	Nossi Bé.
„ 15	„ Daria Dowlat	Nossi Bé.
„ 24	Batel Jairam Parsad	Majunga.
„ 29	Gunja Hedree	Nossi Bé.
„ 31	Batel Daulat Parsad	Majunga.
b. 1	Gunja Daulat Parsad	Comoro.
„ 4	„ Kulter Parsad	Mayotta.
„ 4	„ Duruka Parsad	Majunga.
„ 4	„ Fatch Halbat	Mayotta.
„ 5	„ Sugar Parsad	Comoro.
„ 15	„ Fatch Karim	Majunga.
ar. 2	„ Ali Madat	Majunga.
„ 7	„ Fateh Salamat	Mayotta.
„ 7	Batel Sanklee	Comoro.

POST-MONSOON.

ec. 12	Gunja Fateh Salamat	Nossi Bé.
„ 16	„ Ali Madat	Dioga Saurez.
„ 17	„ Naran Parsad	Mayotta.
„ 19	„ Luckmi Parsad	Mayotta.
„ 24	Batel Husseinie	Mayotta.

V. The known facts of the case may thereupon be summarised as follows:—

1. Tamatave is said to be infected about or after the 14th November last. It is not known that any other port in the French Colony was, either previously or at the same time, infected with the disease.
2. For fully 12 months prior to the declaration that the disease had made its appearance at Tamatave there had been, so far as steamers are concerned, no connexion whatever, either by vessels in ballast, by cargo, or by passengers, either directly or indirectly, between Bombay and any port in the French Colony of Madagascar.
3. For fully seven months prior to Tamatave being declared an infected port, the traffic by country craft from Bombay had ceased for the monsoons, and moreover, none of the native vessels which left Bombay in the early part of 1898 were bound for Tamatave.
4. It is important to vote that all vessels leaving Bombay carry bills of health, stating the exact number of crew and passengers on the date of departure, and that the minimum period occupied on the voyage is, for steamers, 15 or 16 days, and, for native craft, within the most favourable condition of wind and weather, a month.

S. EVANS,
Assistant to Port Health Officer,
Bombay.

(Signed) J. CRIMMIN, V.C., Major, I.M.S
Port Health Office, Bombay.

8053 — 4053 — 1788 — TOTAL DEATHS FROM PLAGUE BY MONTHS

APPENDIX No. LXXVII.
(See Question No. 26,076, sqq.)

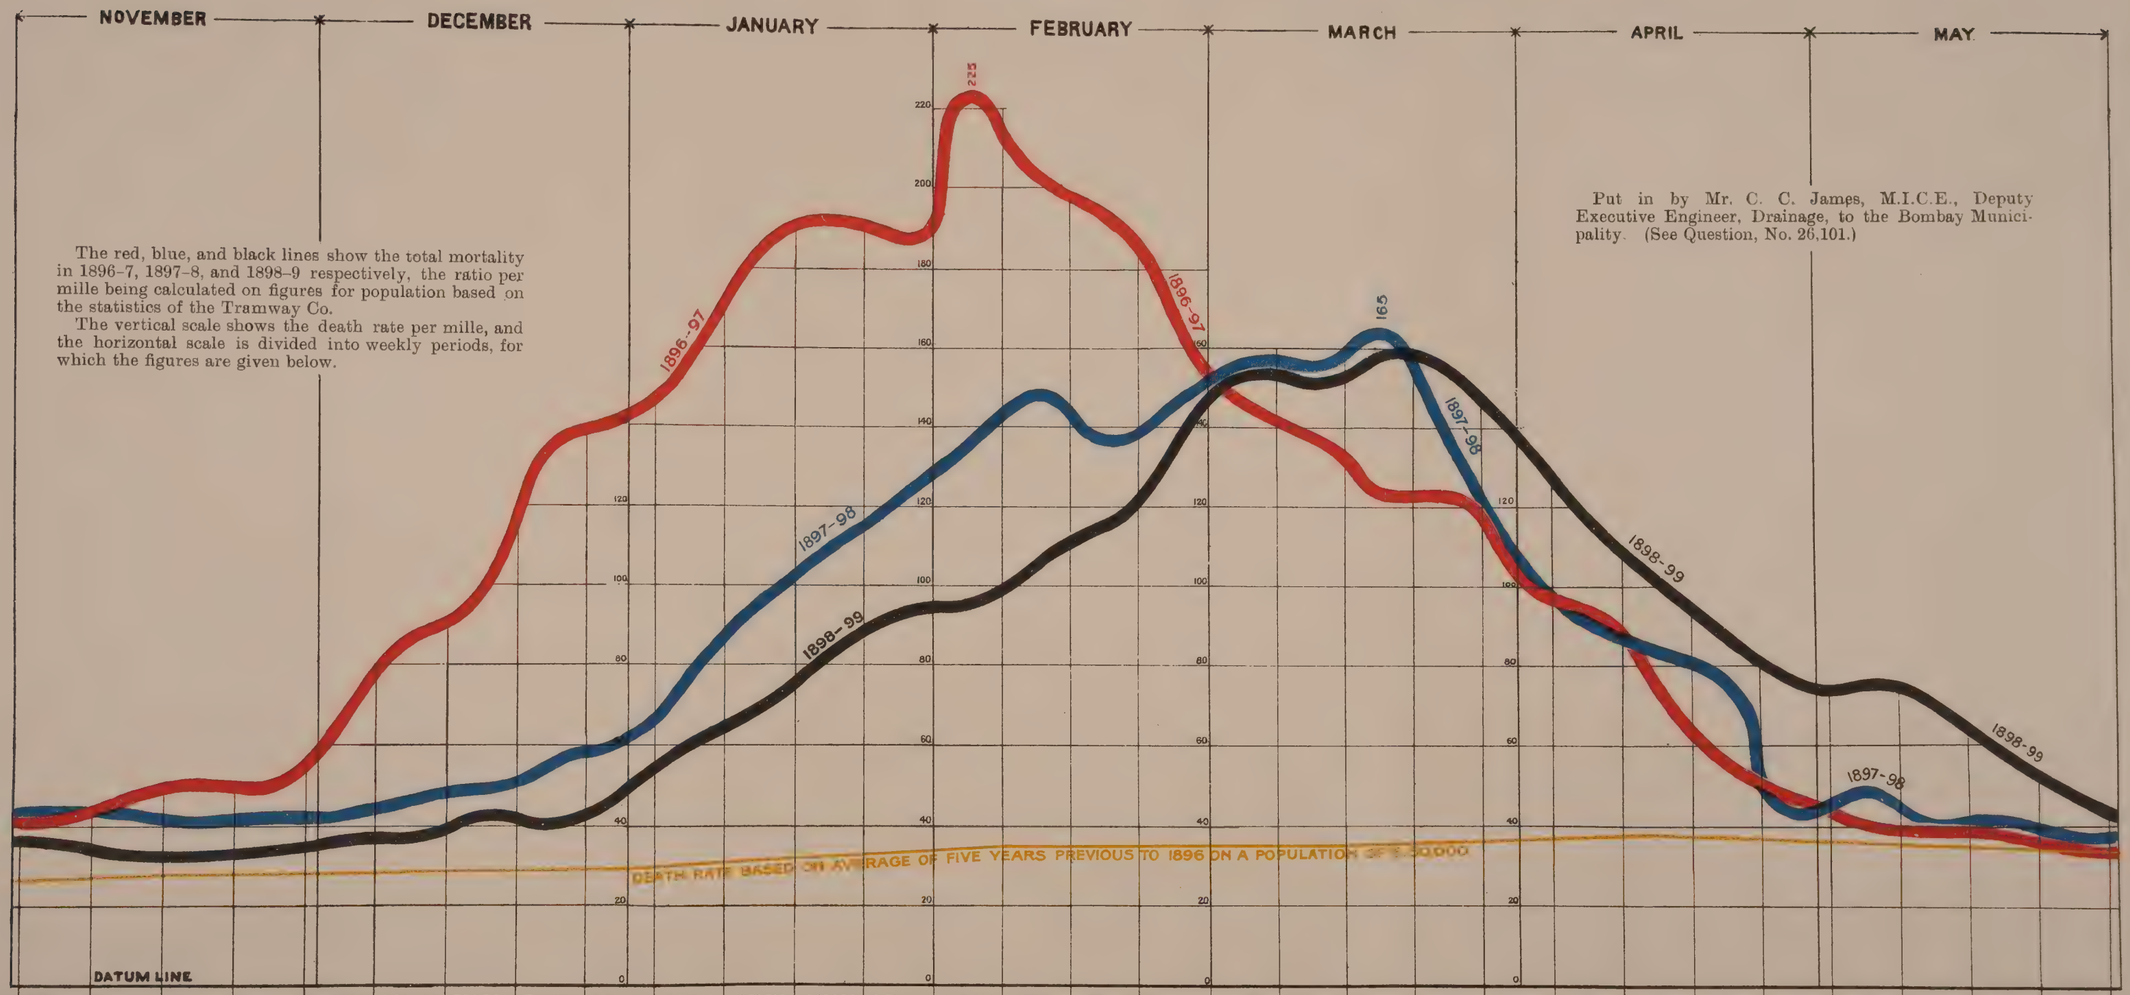
CHART SHOWING WEEKLY DEATH RATE PER 1000 PER ANNUM ON ACTUAL POPULATION

DURING THE PLAGUE EPIDEMIC IN BOMBAY CITY IN 1896-7, 1897-8, AND 1898-9.

The red, blue, and black lines show the total mortality in 1896–7, 1897–8, and 1898–9 respectively, the ratio per mille being calculated on figures for population based on the statistics of the Tramway Co.

The vertical scale shows the death rate per mille, and the horizontal scale is divided into weekly periods, for which the figures are given below.

Put in by Mr. C. C. James, M.I.C.E., Deputy Executive Engineer, Drainage, to the Bombay Municipality. (See Question, No. 26,101.)



IN 1896-97	POPULATION	7,65,500	7,74,500	7,83,500	7,92,500	7,97,000	7,70,000	7,32,500	7,01,000	6,21,000	5,31,000	4,83,500	4,62,000	4,52,000	4,42,000	4,37,000	4,37,000	4,52,000	4,67,000	4,71,000	4,75,000	4,80,000	4,95,000	5,32,500	5,67,500	6,17,500	6,80,000	7,04,000	7,12,000	7,20,000	7,28,000

APPENDIX No. LXXIX.

NOTES OF CASES OF PLAGUE

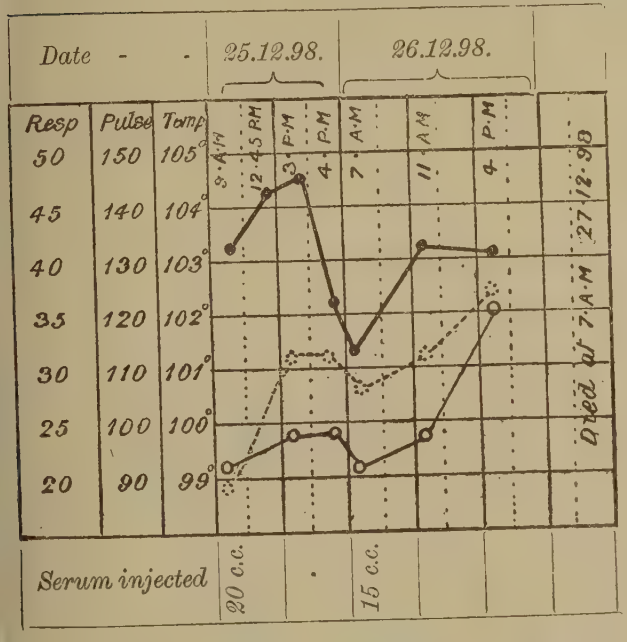
TREATED WITH

ANTI-PESTEUX SERUM FROM THE PASTEUR INSTITUTE (HORSE No. 21.)
AT BANGALORE SOUTH CAMP PLAGUE HOSPITAL.

By Lieut. S. R. DOUGLAS, I.M.S., on Special Duty with the INDIAN PLAGUE COMMISSION.

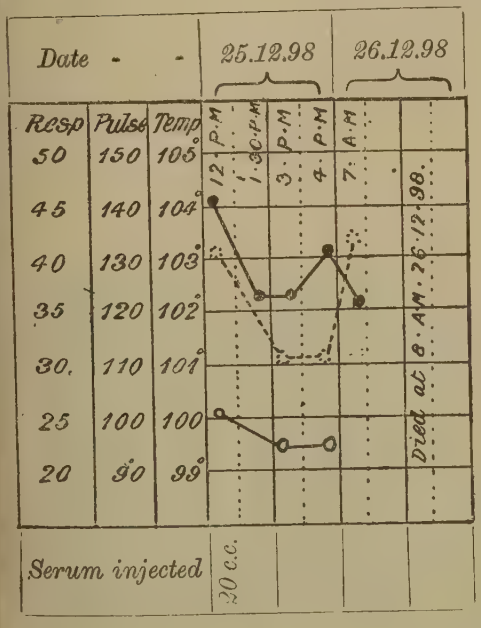
Note.—In the following charts the temperature is shown by a thick black line, the pulse by a thin black line, and the respiration by a dotted line.

CASE No. I. (Admitted on 3rd day of the disease.)



Esoph Beg. Age 45. Male. Admitted **25.12.98.** Fever for three days. Bubo in left groin. No wound of foot or leg on left side. Temperature 103·4°. Pulse 92. Good volume and tension. Respiration 20. Lungs clear. Heart normal. Spleen not felt. 20 *c.c. of serum inoculated* in left flank at 11.30 a.m. 12.45 p.m.—Temp. 104·2°. Patient volunteered the statement that pain in bubo was less. 3 p.m.—Temp. 104·6°. Pulse 96. Respiration 32. No change noticed. 4 p.m.—Temp. 102·2°. Pulse 96. Respiration 32. States that he feels better. **26.12.98.**—7 a.m.—Temp. 101·4°. Pulse 92. Respiration 28. 9 a.m.—15 *c.c. of serum inoculated* left flank. 11 a.m.—Temp. 103·4°. Pulse 96. Respiration 32. 4 p.m.—Temp. 103°. Pulse 120. Respiration 36. Delirious. Decidedly worse.

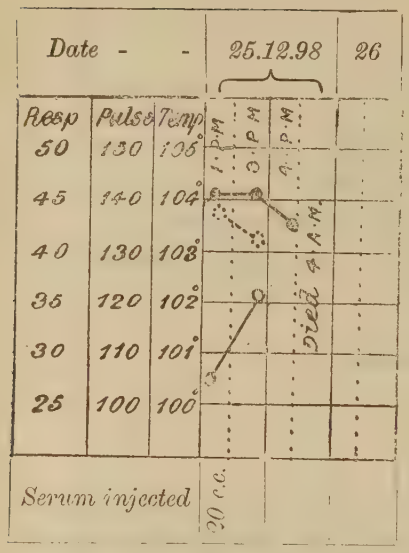
CASE No. II. (Admitted on 2nd day of the disease.)



Ala Raja (a Sais). Age 25. Male. Admitted **25.12.98.** Fever for two days, bubo one day. Bubo in right axilla and also the glands above the clavicle on the same side; a good deal of swelling round it. Temperature 104. Pulse 100. Respirations 40. Tongue brown furred. 20 *c.c. of serum inoculated* (10 c.c. into each flank) at 12.0 p.m. 1.30 p.m.—Temp. 102·4°. 3 p.m.—Temp. 102·4°. Pulse 96. Respiration 32. 4 p.m.—Temp. 103°. Pulse 96. Respiration 32. **26.12.98.**—7 a.m.—Temp. 102·2°. Pulse running; could not be counted. Respiration 44.

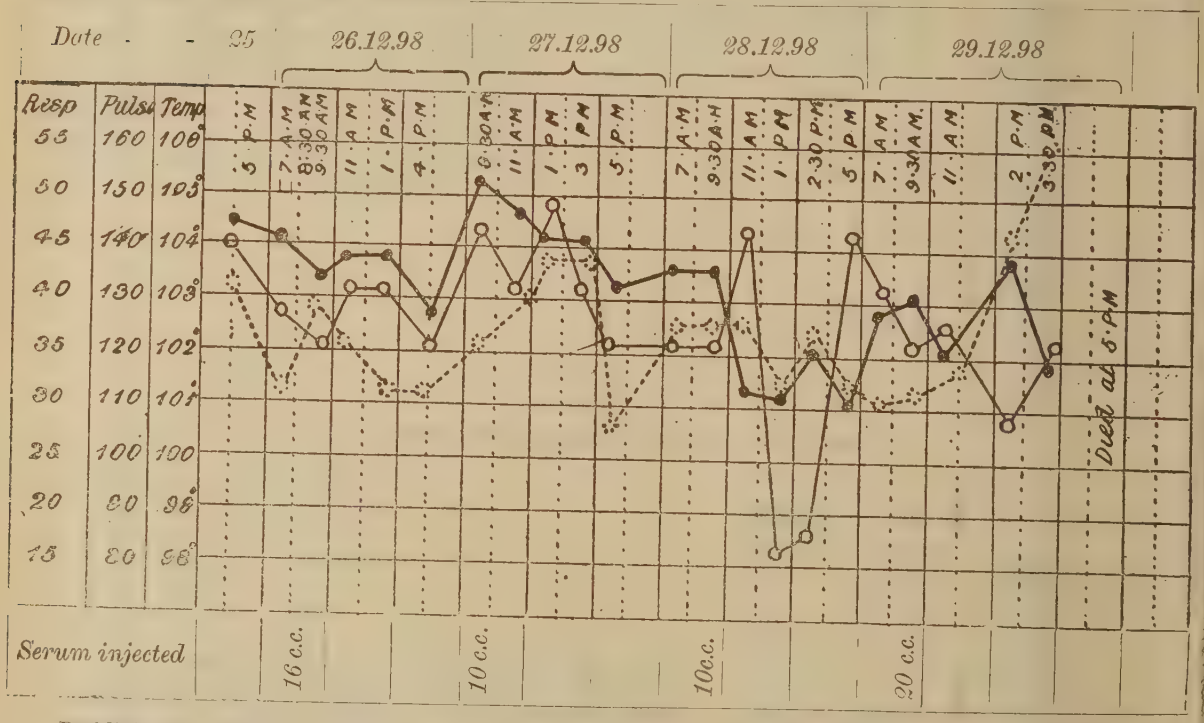
25.12.98.—One case not inoculated as he had a suppurating bubo and was convalescent.

CASE No. III. (Admitted on 3rd day of the disease.)



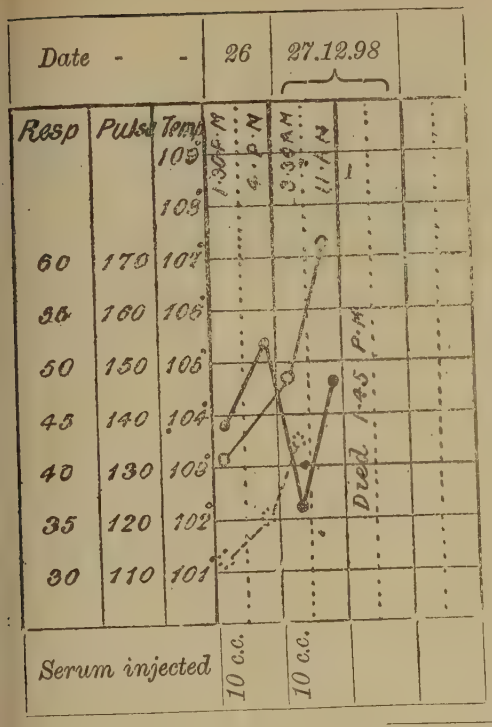
Willammah. Female. Age 25. Admitted **25.12.98.** Fever for three days, had not noticed any bubo. Temperature on admission 99°, patient shivering. Pulse very fast and weak. One ounce of arrack given, and one hour afterwards (1 p.m.) temperature was 104°. Pulse 104, weak and irregular in time and force. Respiration 44. Slightly delirious. Tongue furred; indented at edges. Spleen not felt. Bubo in right axilla. Heart and lungs normal. Left breast very prominent and hard, as if pushed forward by something. 20 *c.c. of serum inoculated* into left flank (1 p.m.). 3 p.m.—Temp. 104°. Pulse 120, distinctly stronger. Respiration 42. 4 p.m.—Temp. 103·8°. Slightly better pulse, but much muscular twitching was present, the head never being still. Patient seemed sensible and quiet.

CASE No. IV. (Admitted on 3rd day of the disease.)



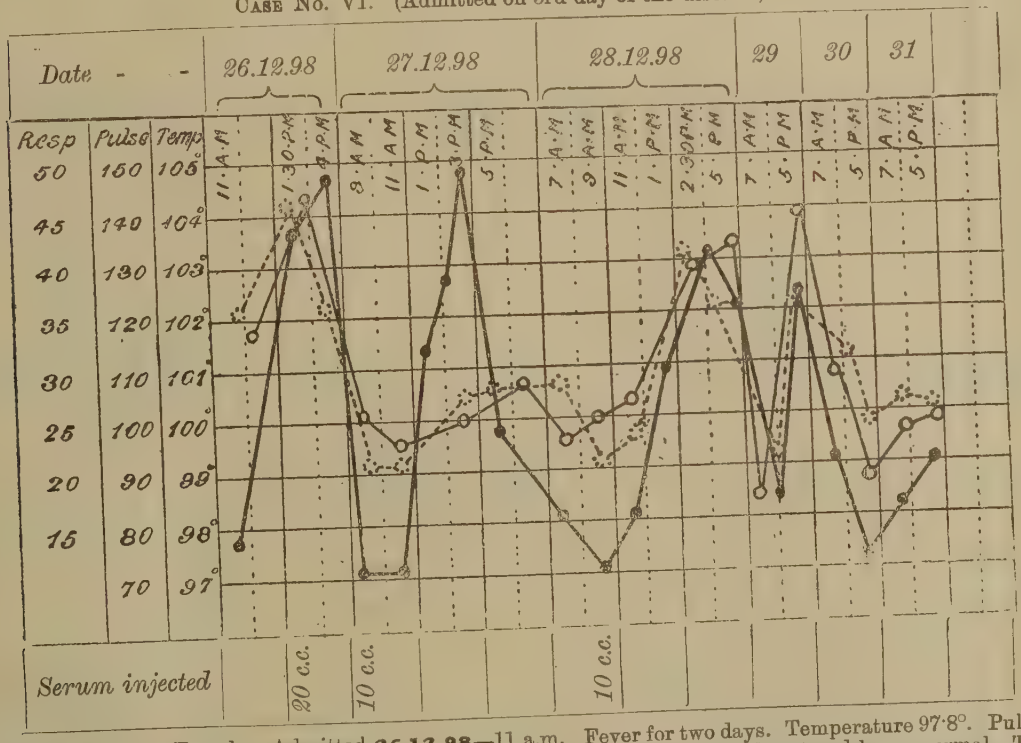
Barkli Amma. Age 20. Female. Admitted **25.12.98** (evening). Fever for two days. Temperature 104·4°. Pulse 140. Respiration 42. Bubo in right axilla. A small suppurating wound, a scratch received three days before illness on inner side of left forearm. Cover-slip preparations taken stained with fuchsin, but nothing resembling a plague bacillus seen. Numerous encapsuled diplococci present. An agar tube inoculated from wound. Cover-slip from tube two colonies, one round, opaque, yellowish, showed cocci in groups; the other smooth, thin, when magnified consisting of minute colonies, showed diplococci in chains. **26.12.98.**—7 a.m.—Temp. 104°. Pulse 128. Respiration 32. 8.30 a.m.—Heart and lungs normal. Spleen not felt. Tongue furred; indented at edges. 16 *c.c. serum inoculated* into right flank. 9.30 a.m.—Temp. 103·6°. Pulse 120. Respiration 40. 11.0 a.m.—Temp. 103·8°. Pulse 132. Respiration 36. 1.0 p.m.—Temp. 103·8°. Pulse 132. Respiration 32. 4.0 p.m.—Temp. 102·8°. Pulse 120. Respiration 32. **27.12.98.**—8.30 a.m.—Temp. 105·2°. Pulse 144. Respiration 36. Looks very much better, quiet and sensible. 10 *c.c. serum inoculated.* 11.0 a.m.—Temp. 104·8°. Pulse 132. Respiration 42. 1.0 p.m.—Temp. 104·4°. Pulse 148. Respiration 44. 3.0 p.m.—Temp. 104·2°. Pulse 132. Respiration 44. Not quite so sensible, but pulse fairly good. 5.0 p.m.—Temp. 103·4°. Pulse 122. Respiration 48. **28.12.98.**—7.0 a.m.—Temp. 103·6°. Pulse 120. Respiration 36. 9.30 a.m.—Temp. 103·6°. Pulse 120, not so strong. Respiration 36. Slightly delirious. 10 *c.c. inoculated* 11.0 a.m.—Temp. 101·2°. Pulse 144. Respiration 36. 1.0 p.m.—Temp. 101·2°. Pulse 92. Respiration 32 2.30 p.m.—Temp. 102°. Pulse 96. Respiration 36. Slightly delirious. 5.0 p.m.—Temp. 101°. Pulse 142. Respiration 32. **29.12.98.**—7.0 a.m.—Temp. 102·8°. Pulse 132. Respiration 30. 9.30 a.m.—Temp. 103°. Pulse 120. Respiration 32. Answered sensibly when spoken to, but restless and talks much to herself. 20 *c.c. inoculated.* 11.0 a.m.—Temp. 102°. Pulse 124. Respiration 36. 2.0 p.m.—Temp. 103·8°. Pulse 108. Respiration 46. 3.30 p.m.—Temp. 102·6. Pulse 120. Respiration 56. Bronchial breathing at left apex. General condition bad. No sputum obtainable. Pulse very weak.

CASE No. V. (Admitted on 2nd day of the disease.)



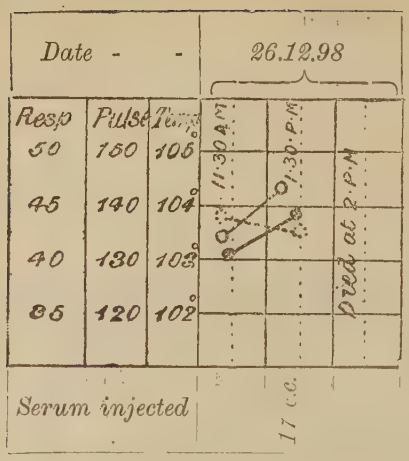
Poopathi. Age 8. Female. Admitted **26.12.98.** Bubo noticed yesterday. Fever came on last night. Bubo in right groin. Temperature 103·8°. Pulse 130. Respiration 32. 1.30 p.m.—No wound discovered on right leg or buttock. 10 *c.c. of serum inoculated.* Spleen not felt. 4 p.m.—Temp. 105·4°. Pulse 148. Respiration 35. **27.12.98.**—8.30 a.m.—Temp. 102. Pulse 180 running very weak. Respiration 43. General condition much worse. A good deal of muscular twitching. 10 *c.c. of serum inoculated* into right flank. 11 a.m.—Temp. 104·8°. Pulse running.

CASE No. VI. (Admitted on 3rd day of the disease.)



Balamah. Age 35. Female. Admitted **26.12.98**—11 a.m. Fever for two days. Temperature 97·8°. Pulse 118. Respiration 35. 1.30 p.m.—Shivering much; talking incoherently. No bubo; heart and lungs normal. Tongue brown; furred. Teeth very dirty, and covered with brown sordes. Temperature 103·6°. Cover-slip of blood taken. Blood preparation stained with eosin and methylene blue. No bacilli of any sort seen, but some malarial parasites present. Pulse, so much muscular tremor that it could not be counted (rigor). Respiration 46. Spleen not felt. 20 *c.c. of serum inoculated* into left flank. 4 p.m.—Temp. 104·6°, Pulse 144. Respiration 36. **27.12.98**—8 a.m.—Temp. 97°. Pulse 100. Respiration 20. Patient looks much better. Tongue still very foul. 10 *c.c. inoculated.* 11 am.—Temp. 97°. Pulse 96. Respiration 20. 1 p.m.—Temp. 101·4°. Pulse could not be taken on account of muscular tremor (rigor). 3 p.m.—Temp. 104·6°. Pulse 100. Respiration 27. Pulse very good considering temperature, and remarkably slow. 5 p.m.—Temp. 99·8°. Pulse 108. Respiration 28. **28.12.98.**—7 a.m.—Temp. 98°. Pulse 96. Respiration 28. 9 a.m.—Temp. 97°. Pulse 100. Respiration 30. 10 *c.c. inoculated.* 11 a.m.—Temp. 98°. Pulse 104. Respiration 24. 1 p.m.—Temp. 101; shivering much. Pulse and respiration could not be taken. 2.30 p.m.—Temp. 103·2°. Pulse 128. Respiration 40. Still shivering but skin moist. 5 p.m.—Temp. 102. Pulse 132. Respiration 36. **29.12.98.**—7 a.m.—Temp. 98·4°. Pulse 84. Respiration 22. 9.30 a.m.—Quite comfortable; looks like a severe case of malaria. No serum inoculated, but Quinine, gr., X. ordered at once; and to be repeated when sweating stage was reached. 5 p.m.—Temp. 103·2°. Pulse 140°. Respiration 35. **30.12.98.**—7 a.m.—Temp. 99°. Pulse 108. Respiration 36. 5 p.m.—Temp. 97·2°. Pulse 88. Respiration 24. **31.12.98.**—7 a.m.—Temp. 98·2°. Pulse 98. Respiration 26. 5 p.m.—Temp. 99° Pulse 100. Respiration 24. 9 a.m.—Temp. 97. Pulse 72. Respiration 20. Convalescent.

26.12.98. One not inoculated as she had had a large abscess on the middle of the right thigh for 12 days. This abscess had burst, laying bare the muscle, and a large slough was protruding. Over the head of the left fibula was another abscess. Patient very ill with high temperature. Very foul brown tongue. (?) Plague in carbuncular form.

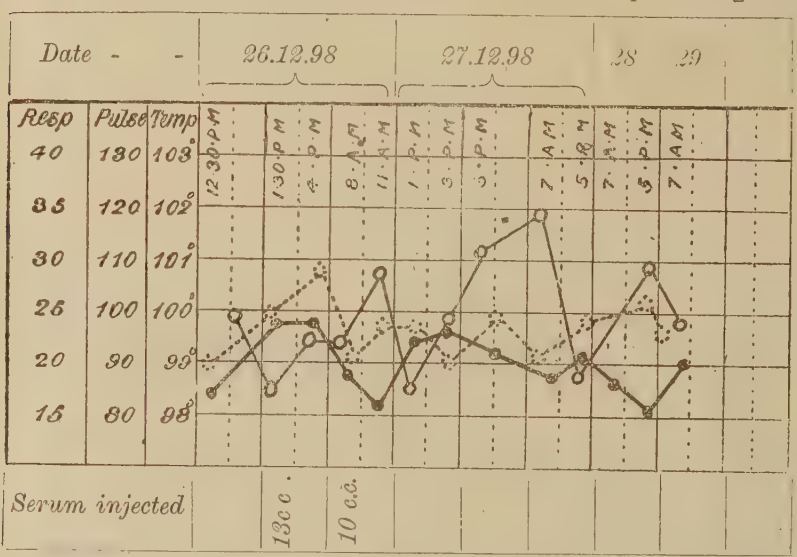


CASE No. VII. (Admitted on 2nd day of the disease.)

Almail. Age 30. Female. Admitted **26.12.98**—11.30 a.m. Fever only one day. Bubo in right groin. No wound discovered. Temperature 103°. Pulse 132. Respiration 44. 1.30 p.m.—General condition very bad, 5½ months pregnant. Temp. 103·8°. Pulse 144, weak and irregular. Respiration, gasping, 44. Patient very restless. Heart and lungs normal as far as could be ascertained. 17 *c.c. of serum injected* into left flank. 2 p.m.—Died (half hour after injection). Practically moribund on admission.

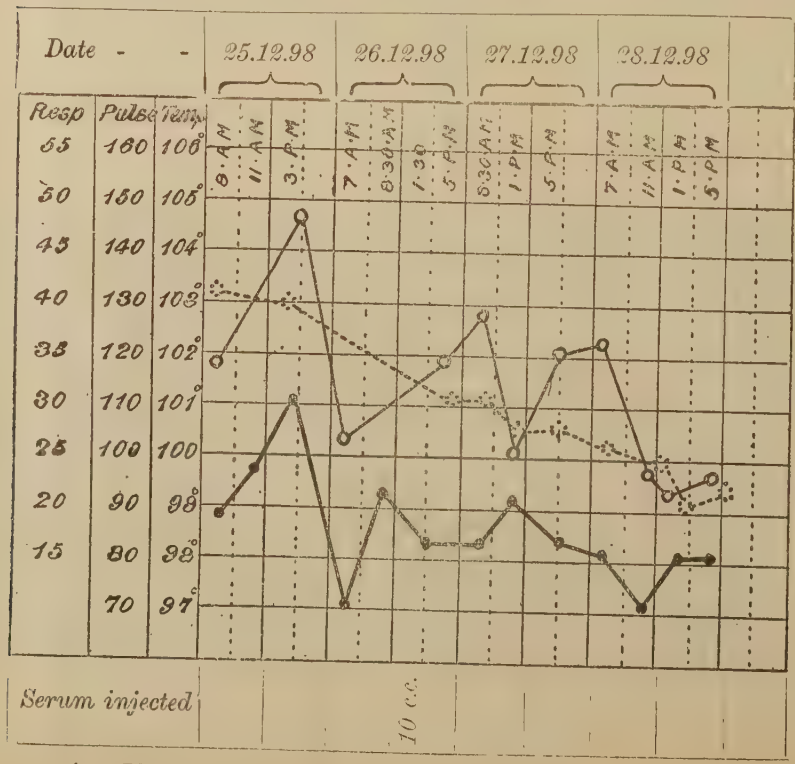
CASE No. VIII. (Admitted on 6th day of the disease.)

Lutchmee. Age 13. Female. Admitted **26.12.98**. 12.30 p.m. Five days ago fever. Four days ago bubo noticed. Temp. 98·4°. Pulse 100. Respiration 20. 1.30 p.m.—Tongue slightly furred. Lungs and heart normal. Bubo in right inguinal and also right femoral glands. No wound of right leg or foot discovered. General condition good. Spleen not enlarged. Temp. 99·8°. Pulse 84. Respiration 24. 13 *c.c. of serum inoculated* into right flank. 4 p.m.—Temp. 99·8°. Pulse 98. Respiration 28. General condition very good. **27.12.98.**—8 a.m.—Temp. 98·8°. Pulse 96. Respiration 22. Looks quite well. 10 *c.c. inoculated.* 11 a.m.—Temp. 98·2°. Pulse 108. Respiration 24. 1 p.m.—Temp. 99·4°. Pulse 84. Respiration 23. 3 p.m.—Temp. 99·6°. Pulse 96. Respiration 20. 5 p.m.—Temp. 99·2°. Pulse 112. Respiration 25. **28.12.98.**—7 a.m.—Temp. 98·8°. Pulse 120. Respiration 20. Seems quite well. Not injected. 2.30 p.m.—Bubo still present but scarcely tender on pressure. 3 p.m.—Temp. 99°. Pulse 88. Respiration 24. **29.12.98**—7 a.m.—Temp. 98·6°. Pulse 88. Respiration 22. Convalescent. 5 p.m.—Temp. 98°. Pulse 110. Respiration 26. **30.12.98.**—7 a.m.—Temp. 99°. Pulse 98. Respiration 24. Bubo still present. Removed to convalescent ward. **1.1.99.**—Bubo suppurating, opened.

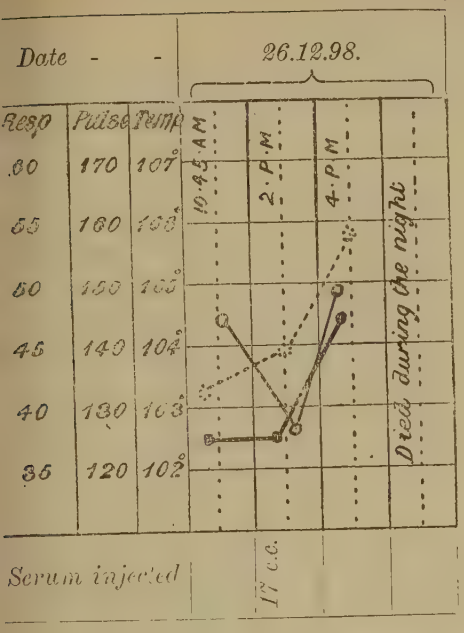


CASE No. IX. (Admitted on 3rd day of the disease.)

Beersi. Age 12. Female. Admitted **25.12.98**: early morning. Two days fever. Temperature 98·8°. Pulse 118. Respiration 42. Râles and rhonchi heard over the whole of the right lung, a few over the left. No bubo found. 11 a.m.—Temp. 99·6°. 3 p.m.—Temp. 101°. Pulse 148. Respiration 40. Tongue covered with a thin layer of white fur, rather flabby. **26.12.98.**—7 a.m.—Temp. 97°. Pulse 102. Respiration 36. 8.30 a.m.—No cough or sputum. General condition good. Temp. 99·4°. Pulse fair volume and tension. Tongue covered with white fur, indented at the edges ("typical plague tongue"). 1.30 p.m.—10 *c.c. serum inoculated* into left flank. 4 p.m.—Temp. 98·4°. Pulse 120, good. Respiration 32. **27.12.98**—8.30 a.m.—Temp. 98·4. Pulse 128. Respiration 32. 1 p.m.—Temp. 99·2. Pulse 100. Respirations 28. No serum given. 5 p.m.—Temp. 98·4°. Pulse 120. Respiration 28. **28.12.98.**—7 a.m.—Temp. 98°. Pulse 122. Respiration 26. No inoculation. 11 a.m.—Temp. 97°. Pulse 96. Respiration 24. 1 p.m.—Temp. 98°. Pulse 92. Respiration 22. 2.30 p.m.—Practically convalescent. A few squeaks heard in the lungs. 5 p.m.—Temp. 98. Pulse 96. Respiration 24. **29.12.98**—7 a.m.—Temp. 98·4°. Pulse 84. Respiration 22. Convalescent.

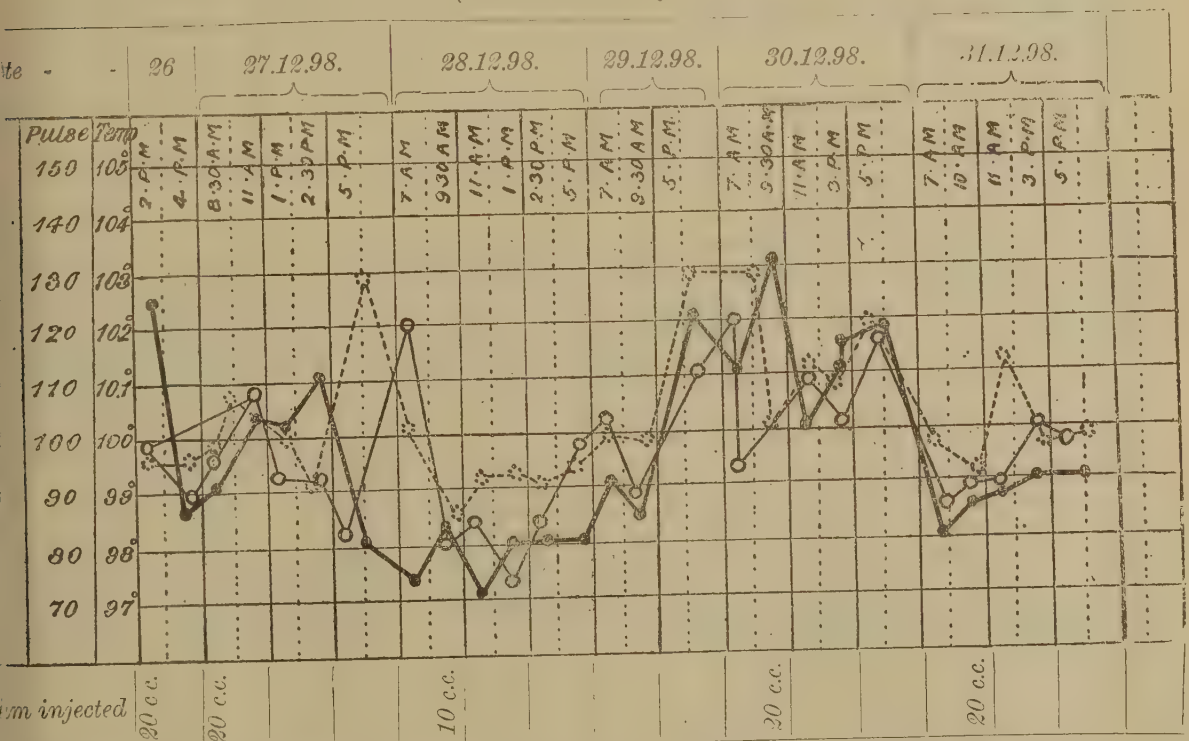


CASE No. X. (Admitted on 3rd day of the disease.)



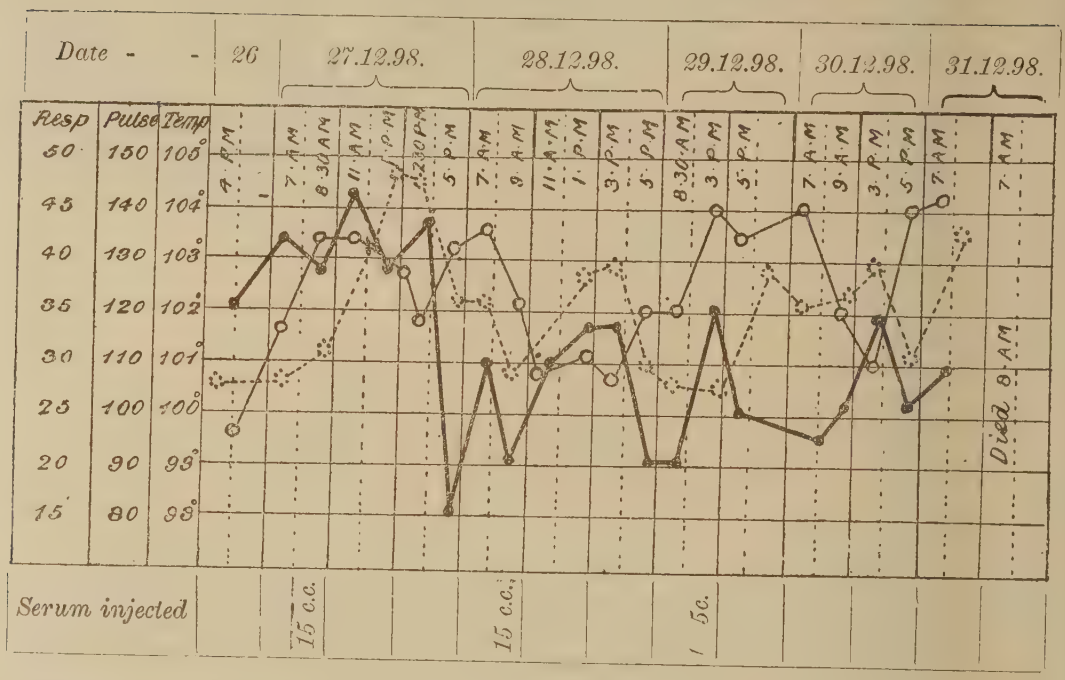
Gnana Moothoo. Aged 40. Male. Admitted **26.12.98** 10.45. a.m. Fever and bubo for two days. Temp. 102·6°. Respirations 42. Pulse 146. 2 p.m.—General condition bad, Much muscular tremor. A very large submaxillary bubo filling up the whole space between the jaw and the clavicle on the left side; the œdema spreading far down on to the chest. Temp. 102·6°. Pulse 124. Respiration 44. Great difficulty in swallowing and unable to open the mouth more than about half an inch, so that the condition of the inside of the mouth could not be observed. Spleen not enlarged. Heart and lungs normal. 17 *c.c. of serum inoculated* into left flank. 4 p.m.—Temp. 104·6°. Respiration 54. Pulse 148.

CASE No. XI. (Admitted on 4th day of the disease.)



Sewasagayan. Age 48. Male. Admitted **26.12.98** : morning. Fever for three days. Temp. 102·6°. Pulse 100. Respiration 24. 2 p.m.—General condition fair. Tongue furred, brown, indented at edges. Eyes bloodshot, tears running over the face in large quantities. Heart and lungs normal. Bubo in left inguinal region, no wound found. 20 *c.c. of serum inoculated* in left flank. 4 p.m.—Temp. 98·8°. Pulse 88. Respiratior 24. **27.12.98.** —8.30 a.m.—Glands enlarged on both sides of the neck to a slight degree, more especially on the right side. Temp. 99°. Pulse 96. Respiration 24. 20 *c.c. serum inoculated.* 11 a.m.—Temp. 100·4°. Pulse 108. Respiration 28. 1 p.m.—Temp. 100·2°. Pulse 92. Respiration 25. 2.30 p.m.—Temp. 101°. Pulse 92. Respiration 20. General condition the same. No worse. 5 p.m.—Temp. 98°. Pulse 84. Respiration 40. **28.12.98.**—7 a.m.—Temp. 97·6°. Pulse 120. Respiration 25. 9.30 a.m.—Temp. 98·4°. Pulse 80. Respiration 16. 10 *c.c. inoculated.* Patient feels quite well. 11 a.m.—Temp. 97°. Pulse 84. Respiration 22. 1 p.m.—Temp. 98. Pulse 72. Respiration 23. 2.30 p.m.—Temp. 98°. Pulse 84. Respiration 20. 5 p.m.—Temp. 98°. Pulse 96. Respiration 22. **29.12.98.**—7 a.m.—Temp. 99°. Pulse 102. Respiration 25. 9.30 a.m.—Temp. 98·4°. Pulse 88. Respiration 24. Bubo small, very slightly tender. Not inoculated. 5 p.m.—Temp. 102°. Pulse 110. Respiration 40. **30.12.98.**—7 a.m.—Temp. 101°. Pulse 120. Respiration 40. 9.30 a.m.—Temp. 103°. Pulse 92. Respiration 24. 20 *c.c. inoculated.* 11 a.m.—Temp. 100°. Pulse 108. Respiration 28. 3 p.m.—Temp. 101·4°. Pulse 100. Respiration 28 5 p.m.—Temp. 101·8°. Pulse 118. Respiration 34. **31.12.98.**—7 a.m.—Temp. 98°. Pulse 84. Respiration 24. 10 a.m.—Temp. 98·4°. Pulse 88. Respiration 20. 20 *c.c. inoculated.* 11 a.m.—Temp. 98·6°. Pulse 88. Respiration 32. 3 p.m.—Temp. 99°. Pulse 100. Respiration 23. Patient says he feels quite well, bubo the same size, very little surrounding œdema. 5 p.m.—Temp. 99°. Pulse 88. Respiration 24. **1.1.99.**—7 a.m.—Temp. 98°. Pulse 88. Respiration 18. Convalescent.

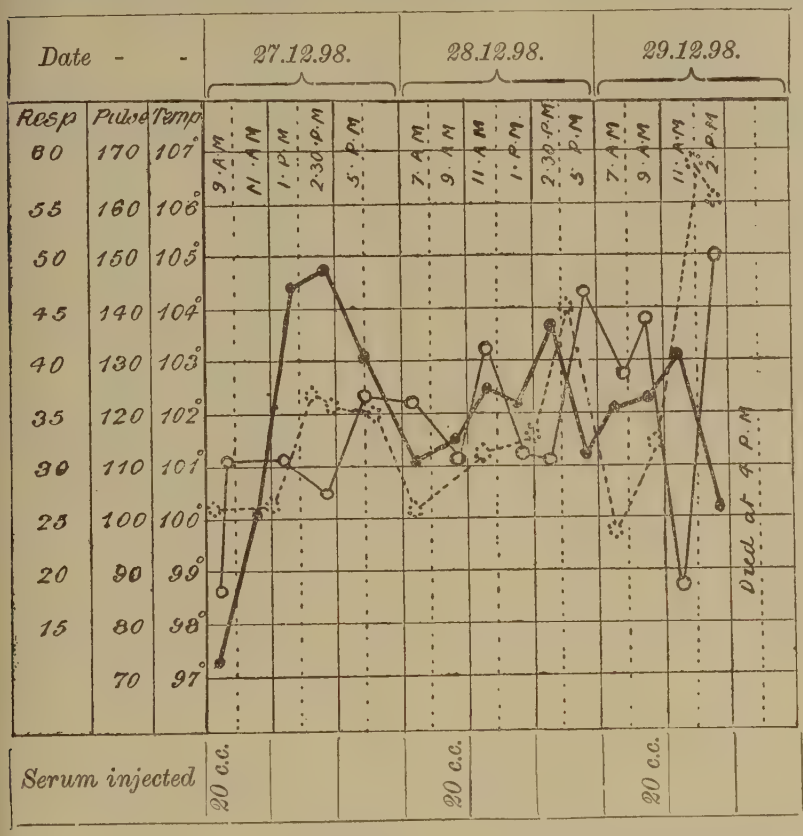
CASE No. XII. (Admitted on 3rd day of the disease.)



Goondappah. Aged 12 (looks much younger). Male. Admitted 4 p.m., **26.12.98.** Two days ago fever, one day ago bubo. On admission, temperature 102°. Pulse 98. Respiration 28. **27.12.98.**—7 a.m.—Temp. 103·4°. Pulse 118. Respiration 28. 8.30 a.m.—Temp. 102·8°. Pulse 132. Respiration 32. Tongue furred. Spleen not felt. Heart and lungs normal. Slight cough. No sputum. Bubo in right axilla. Not delirious. General condition, fair. 15 *c.c. inoculated.* Wound on right foot suppurating; seven days old. 11 a.m.—Temp. 104·2°. Pulse 132. Respiration 42. 1 p.m.—Temp. 102·8°. Pulse 128. Respiration 48. 2.30 p.m.—Temp. 103·8°. Pulse 116. Respiration 48. 5 p.m.—Temp. 98°. Pulse 132. Respiration 36. **28.12.98.**—7 a.m.—Temp. 101°. Pulse 136. Respiration 36. General condition, good; rather better than yesterday. 9 a.m.—Temp. 99°. Pulse 120. Respiration 28. 15 *c.c. of serum inoculated* into left flank. 11 a.m.—Temp. 101°. Pulse 108. Respiration 27. 1 p.m.—Temp. 101·4°. Pulse 110. Respiration 38. 3 p.m.—Temp. 101·4°. Pulse 108. Respiration 40. General condition very good. Lungs clear. 5 p.m.—Temp. 99°. Pulse 120. Respiration 30. Bubo smaller, not so painful. **29.12.98.**—8.30 a.m.—Temp. 99°. Pulse 120. Respiration 28. Tongue clean. General condition very good, so not inoculated. 3 p.m.—Temp. 102°. Pulse 140. Respiration 28. Skin moist, tongue clean. 15 *c.c. inoculated* on account of rise of temperature. 5 p.m.—Temp. 100°. Pulse 136. Respiration 40. **30.12.98.**—7 a.m.—Temp. 99·6°. Pulse 140. Respiration 36. 9 a.m.—Temp. 100·2°. Pulse 120. Respiration 36. Peevish sleeps continually. Tongue clean. 3 p.m.—Temp. 102°. Pulse 110. Respiration 40. A small bleb* has formed over the site of bubo surrounded by a purplish spot, much œdema round the bubo. 5 p.m.—Temp. 99·6°. Pulse 140. Respiration 25. **31.12.98.**—7 a.m.—Temp. 101°. Pulse 144. Respiration 48. The glands on both sides of the neck have enlarged during the night.

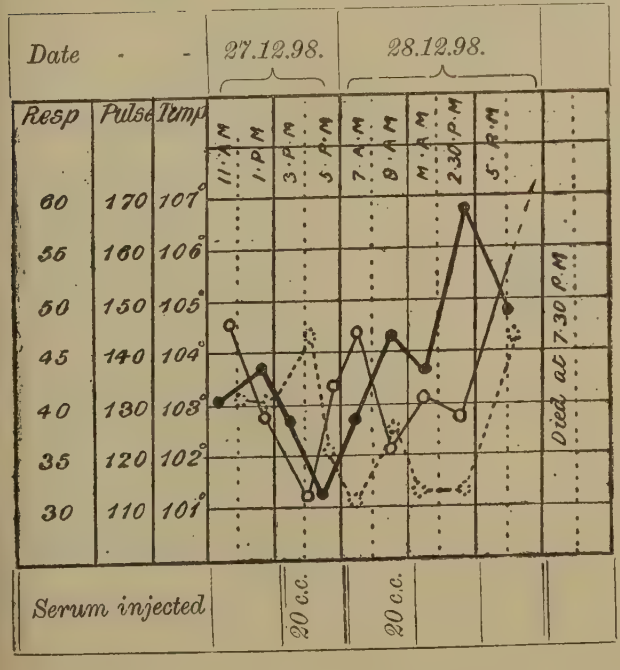
* A cover-slip preparation was taken from this bleb, which contained clear serum, and showed numerous bacilli, more or less shapeless masses. An agar tube was also inoculated.

CASE No. XIII. (Admitted on 5th day of the disease.)



Tukajee Rao. Age 25. Male. Admitted **27.12.98.**—9 a.m. Fever and bubo for four days. Patient staggering like a drunken man. Eyes suffused, unsteady voice, very dull. Pupils contracted. Temperature 98·4°. Pulse 96. Respiration 32. Bubo, one in right groin and another in right axilla; no wound found. Heart normal. Lungs, râles and rhonchi (principally rhonchi) and sibilus in left lung. Spleen could not be felt. 20 *c.c. inoculated.* 11 a.m.—Temp. 101°. Pulse 120. Respiration 32. 1 p.m.—Temp. 105·4°. Pulse 120. Respiration 44. 2.30 p.m —Temp. 105·6°. Pulse 116. Respiration 40. 5 p.m.—Temp. 104°. Pulse 134. Respiration 40. **28.12.98.**—7 a.m.—Temp. 102·2°. Pulse 132. Respiration 30. 9 a.m.—Patient very restless and delirious. Tongue dry and brown. Pupils contracted. Temp. 102·6°. Pulse 120. Respiration could not be taken. 20 *c.c. inoculated.* 11 a.m.—Temp. 103·6.°Pulse 144. Respiration 36. 1 p.m.—Temp. 103·2°. Pulse 126. Respiration 38. 2.30 p.m.—Temp. 104·4°. Pulse 120; irregular in time. Respiration not taken on account of excessive talking, very restless; had to be tied in bed. 5 p.m. — Temp. 102·4°. Pulse 156. Respiration 50. **29.12.98.**—7a.m.—Temp. 103°. Pulse 136. Respiration 28. Very delirious all night, did not sleep. 9 a.m.—Temp. 103·2°. Pulse 148. Respiration 36. 20 *c.c. inoculated.* Talking incessantly, pulse very weak. Lungs, squeaks heard. 11 a.m.—Temp. 104°. Pulse 96. Respiration 76. 2 p.m.—Temp. 101°. Pulse 160. Respiration 60. Bronchial breathing at both apices, especially the left, base of lungs clear, moribund. A cover glass preparation taken of sputum half hour before death stained with eosine and methylene blue, large quantities of diplococci and other micro-organisms seen and two small groups of polar staining bacilli. A cover glass preparation of the blood taken at the same time showed no bacilli or cocci. 4 p.m.—Had a long convulsion and died.

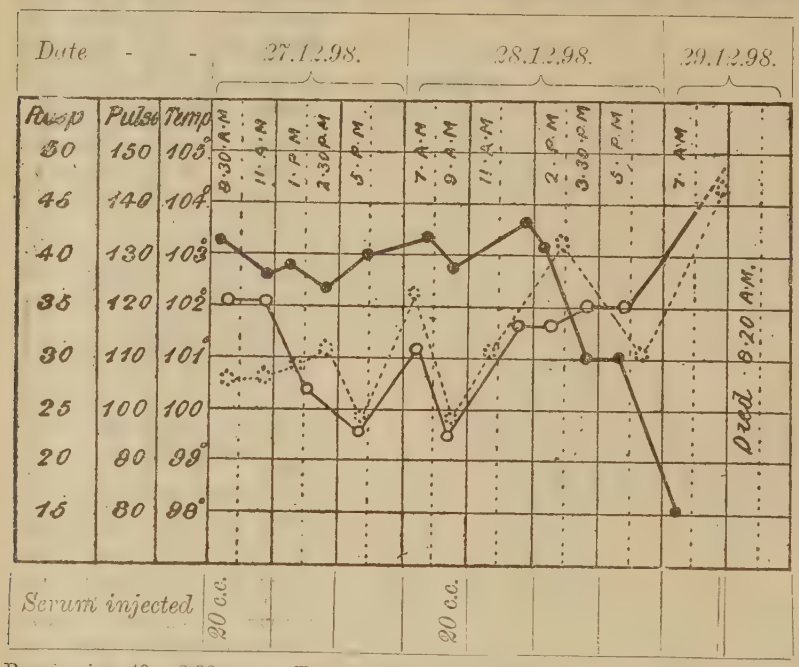
CASE No. XIV. (Admitted on 3rd day of the disease.)



Ramiah. Aged 15. Admitted **27.12.98.**—11 a.m. Fever and bubo two days. Temperature 103°. Pulse 144. Respiration 40. 1 p.m.—Temp. 103·4°. Pulse 128. Respiration 38. 3 p.m.—General condition moderate, dull, stupid. Bubo in right femoral glands. No wound detected. Heart and lungs normal. Eyes suffused. Spleen not felt. Temp. 102·8°. Respiration 48. Pulse 112. 20 *c.c. of serum inoculated* into right flank. 5 p.m.—Temp. 101·6°. Pulse 132. Respiration 35. **28.12.98.**—7 a.m. Temp. 102·8°. Pulse 144. Respiration 32. 9 a.m.—Temp. 104·6 . Pulse 120, very irregular in time and force. Respiration 36. Delirious. Tongue dry. 20 *c.c. inoculated.* 11 a.m.—Temp. 103·8°. Pulse 132. Respiration 32. 1 p.m.—Temp., &c. not able to be taken on account of violent delirium. 2.30 p.m. — Temp. 106·6°. Patient sponged, before which he was dull, apathetic, not answering when spoken to, but afterwards talked rationally, answering questions. Respiration 32. Pulse 128. 5 p.m.—Temp. 104·8°. Pulse running could not be counted. Respiration 148.

Case No. XV. (Admitted on ? day of the disease.)

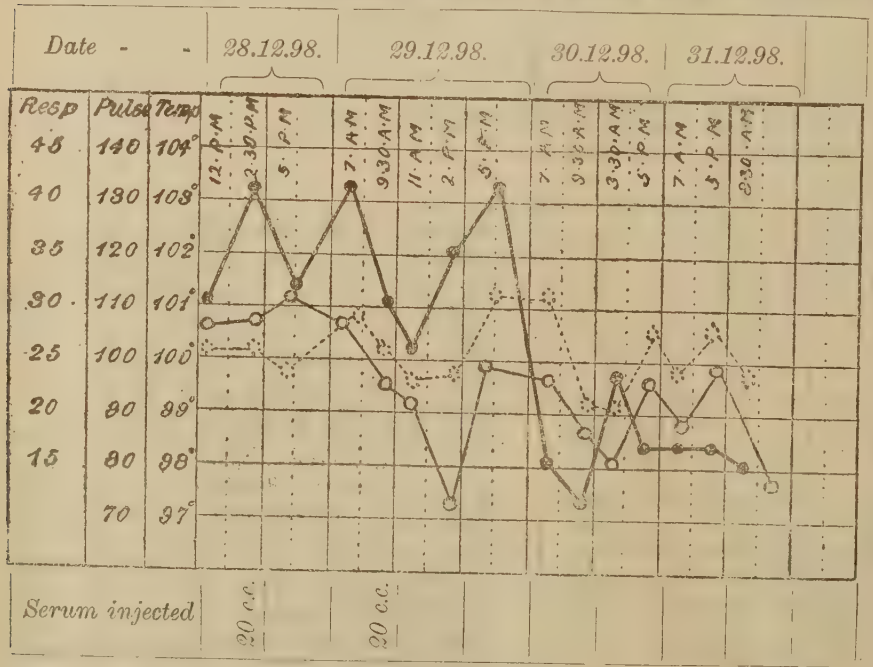
Mooniamah. Aged 55. Female. Admitted **27.12.98.**—7.30 p.m. History, none obtainable. So violently delirious that no temperature or other observations could be obtained. **28.12.98.**—8.30 a.m.—General condition bad. Very delirious still, but not violent, talking much, occasional slight cough. Tongue could not be seen. Eyes very suffused. Temp. 103.2°. Pulse 120. Respiration 28. 20 *c.c. inoculated.* Speen not felt. No bubo could be found. 11 a.m.—Temp. 102·6°. Pulse 120. Fair volume and tension. Respiration 28. 1 p.m.—Temp. 102·8°. Pulse 120. Respiration 30. 2.30 p.m. — Temp. 102·4°. Pulse 104. Respiration 32. Heart and lungs normal. 5 p.m.—Temp. 103°. Pulse 98. Respiration 24. **29.12.98.**—7 a.m.—Temp. 103·4°. Pulse 112. Respiration 36. 9 a.m.—Temp. 102·8°. Pulse 96. Respiration 24. Patient quiet but dull, no delirium, but will not put out her tongue when told to, which, however, does not look nearly so dry and cracked. No bubo found. 20 *c.c. of serum inoculated.* 11 a.m.—Temp. 103·6°. Pulse 116. Respiration 32. 2 p.m. —Temp. 103·2°. Pulse 116.



Respiration 42. 3.30 p.m.—Temp. 101°. Pulse 120. Respiration 40. General condition fair. 5 p.m.—Temp. 101°. Pulse 120. Respiration 30. **30.12.98.**—7 a.m.—Temp. 98°. Pulse running could not be counted. Respiration 48.

Case XVI. (Admitted on 2nd day of the disease.)

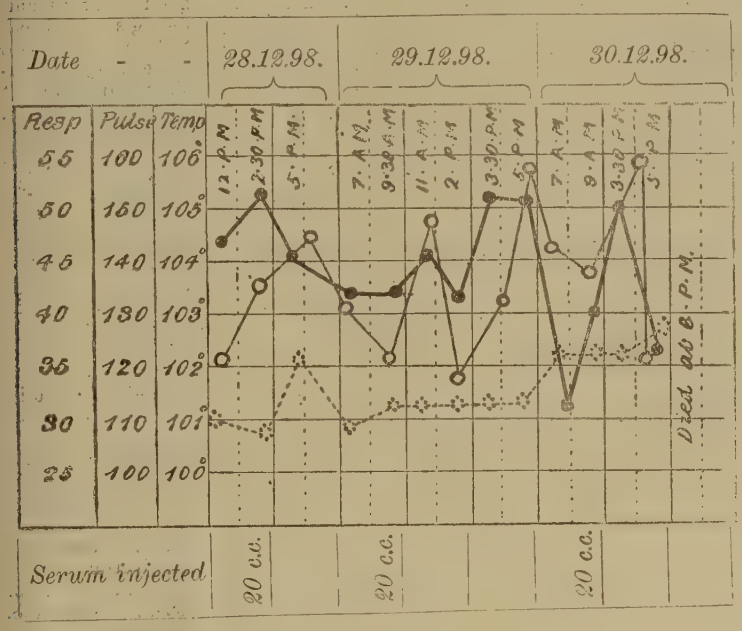
Nagamah. Age 50. Female. Admitted **28.12.98.**—12 p.m. Fever for day. Temperature 101°. Pulse 108 Respiration 26. 2.30 p.m.—General condition fair. Heart and lungs normal. Quite sensible. Spleen not felt. Tongue red at the tip; slight fur. Bubo in the left axilla not noticed before admission. Temp. 103·4°. Pulse 108°. Respiration 26. 20 *c.c. inoculated* into left flank. 5 p.m.—Temp. 101·4°. Pulse 112. Respiration 24. **29.12.98.**—7a.m.—Temp. 103·2°. Pulse 108. Respiration 28. 9.30 a.m.—Temp. 101°. Pulse 96. Respiration 26. General condition good. Bubo not painful. 20 *c.c. inoculated.* 11 a.m. — Temp. 100·2°. Pulse 92. Respiration 23.2 p.m.—Temp. 102.° Pulse 72. Respiration 24. Pulse good: patient seems in a very good condition. 5 p.m.—Temp. 103·4°. Pulse 100. Respiration 32. **30.12.98.**—7 a m.—Temp. 98°. Pulse 96. Respiration 32. 9.30 a.m.—Temp. 97·4°. Pulse 86. Respiration 20. Feels quite well. 3.30 p.m. —Temp. 99·8°. Pulse 80. Respiration 20. 5 p.m.—Temp. 98·4°. Pulse 96. Respiration 28. **31.12.98.** —7 a.m. — Temp. 98·4°. Pulse 86. Respiration 24.



5 p.m.—Temp. 98·4°. Pulse 98. Respiration 28. **1.1.99.**—8.30 p.m.—Temp. 98°. Pulse 76. Respiration 24. Bubo present but not painful. Convalescent.

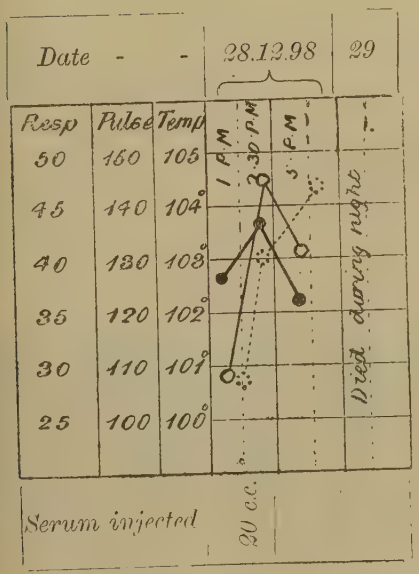
CASE XVII. (Admitted on 2nd day of the disease.)

Gnanama. Age 28. Female. Admitted **28.12.98.** 12 p.m.—Taken ill yesterday; bubo noticed last night. Temperature 104·2°. Pulse 120. Respiration 30. 2.30 p.m.—General condition fair. Heart and lungs clear. Temp. 105·2°. Pulse 132. Respiration 28. Distinct bubo in right groin. Pain complained of in left inguinal region. Small glands felt. Spleen could not be felt. Tongue furred, dry. 20 *c.c. inoculated* into left flank. 5 p.m. —Temp. 104°. Pulse 144. Respiration 36. **29.12.99.**—7 a.m.—Temp. 103·4°. Pulse 132. Respiration 28. 9.30 a.m. —Temp. 103·4°. Pulse 120. Respiration 32. No enlargement of glands or pain felt in the left groin; right bubo unchanged. General condition fair. 20 *c.c. inoculated.* 11 a.m.—Temp. 104°. Pulse 148. Respiration 32. 2 p.m.—Temp. 103·4°. Pulse 118. Respiration 32. 3.30 p.m.—Temp. 105·2°. Pulse 132; weak, and very hard to count. Respiration 32. 5 p.m.—Temp. 105°. Pulse 156. Respiration 32. **30.12.98.**—7a.m.—Temp. 101·2°. Pulse 134. Respiration 36. 9 a.m.—Temp. 103°. Pulse 128. Respiration 36. Dull, slightly delirious. Pulse very small. 20 *c.c. inoculated.* 3.30 p.m. —Temp. 105°. Pulse 156. Respiration 36. 5 p.m.—Temp. 102·4°. Pulse 110. Respiration 38. **31.12.98.**— Violently delirious all night. 6 a.m. —Died.

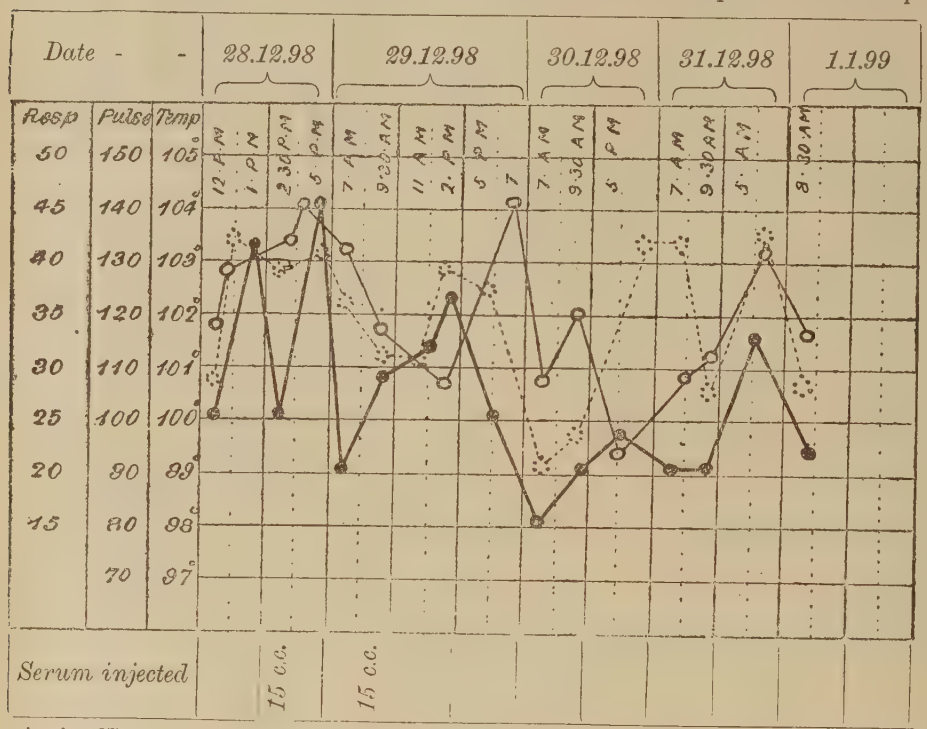


CASE No. XVIII. (Admitted on 7th day of the disease.)

Muriamah. Age 60. Female. Admitted **28.12.98.** Fever for six days. Temperature 102·8°. Pulse 108. Respiration 28. 2.30 p.m.— General condition very bad. Sensible but very weak. Tongue brown and dry, stuffed the roof of the mouth. Temp. 103·6°. Pulse 144. Respiration 40. Shallow. Pulse very small but regular. Bubo in left groin. No wound could be found. Heart normal, but sounds very weak. Lungs congested at the bases. 20 *c.c. of serum inoculated* into left flank. Practically moribund. 5 p.m.—Temp. 102·2°. Pulse 130. Respiration 48.

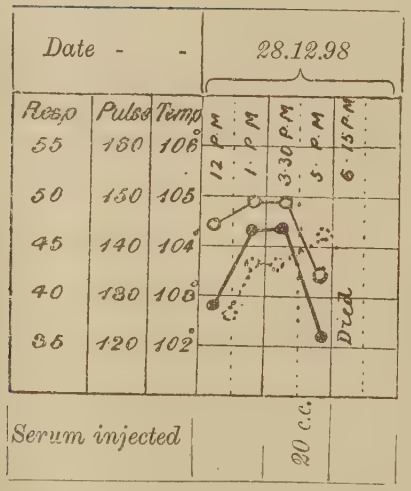


Case No. XIX. (Admitted on 6th day of the disease.)



Coopoo Sawmy. Age 11. Male. Admitted **28.12.98.**—12 p.m. Fever for five days. Temperature 100°. Pulse 118. Respiration 28. 1 p.m.—Temp. 103·4°. Pulse 128. Respiration 42. 2.30 p.m.—General condition good. Heart and lungs normal. Spleen could not be felt. Quite sensible. Bubo in left femoral glands. No wound could be found. Temp. 100°. Pulse 134. Respiration 40. 15 *c.c. inoculated* into left flank. 5 p.m.—Temp. 104°. Pulse 140. Respiration 42. **29.12.98.**—7 a.m.—Temp. 99°. Pulse 132. Respiration 36. 9.30 a.m.—Temp. 100·8° Pulse 118. Respiration 32. 15 *c.c. inoculated.* General condition good. Bubo unchanged. 11 a.m.—Temp. 101·6°. Pulse 112. Respiration 32. 2 p.m.—Temp. 102·4°. Pulse 108. Respiration 40. Quite sensible, feels fairly well. 5 p.m.—Temp. 100°. Pulse 144. Respiration 37. **30.12.98.**—7 a.m.—Temp. 98. Pulse 108. Respiration 22. 9.30 a.m.—Temp. 99°. Pulse 120. Respiration 24. Feels quite well. Not inoculated. Bubo still present. 5 p.m.—Temp. 99·8°. Pulse 94. Respiration 44. **31.12.98.**—7 a.m.—Temp. 99°. Pulse 108. Respiration 44. 9.30 a.m.—Temp. 99°. Pulse 112. Respiration 28. 5 p.m.—Temp. 101·8°. Pulse 133. Respiration 44. **1.1.99.**—8.30 a.m.—Temp. 99·2°. Pulse 116. Respiration 28.

Case No. XX. (Admitted on 6th day of the disease.)

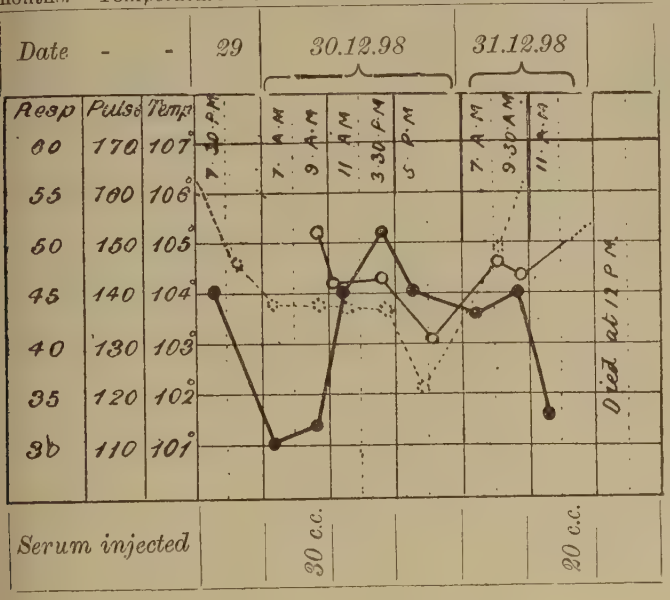


Hanmantha. Age 35. Male. Admitted **28.12.98.**—12 p.m. Fever for four or five days. Bubo for three days. Temperature 102·8°. Pulse 144. Respiration 38. 1 p.m.—Temp. 104·2°. Pulse 148. Respiration 44. 3.30 p.m.—General condition bad. Very dull and apathetic, but answering rationally when spoken to. Quiet, lying still. Tongue very furred, white. Bubo in right femoral region. No wound found. Spleen could not be felt. Temp. 104·2°. Pulse 148. Respiration 44. 20 *c.c. of serum inoculated* into left flank. 5 p.m.—Temp. 102·2°. Pulse 132. Respiration 46.

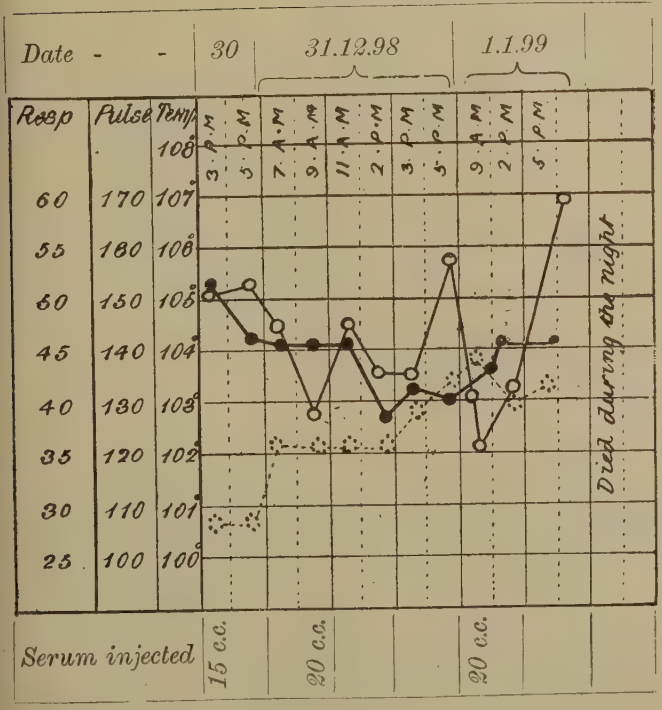
28.12.98.—One patient was admitted at the same time as cases Nos. XVI. to XX., but died almost immediately afterwards, and was not seen by me.

CASE No. XXI. (Admitted on 8th day of the disease.)

Nursamah. Age 25. Female. Admitted **29.12.98.**—7.30 p.m. Fever for eight days, and also pain in the left popliteal space. Six days ago swelling noticed in left axilla. Four days ago aborted. Fœtus about four months. Temperature 104°. Pulse uncountable. Respiration 48. **30.12.98.**—7 a.m.—Temp. 101. Pulse uncountable. Respiration 44. 9 a.m.—General condition bad. Tongue very clean considering. Pulse very rapid but fair volume. Buboes in left axilla and left popliteal space. No wound found. No offensive discharge from the vagina or pain on pressing the lower part of the belly. Temperature 101·6°. Pulse 152. Respiration 44. 30 *c.c. of serum inoculated.* 11 a.m.—Temp. 104·4°. Pulse 140. Respiration 44. 3.30 p.m.—Temp. 105·2°. Pulse 144. Respiration 44. Left lung dull on percussion. Bronchial breathing heard over dull area. A preparation stained with fuchsin showed numerous bipolar stained bacilli, also pneumococci and cocci. An agar tube was inoculated. Sputum in small quantities very like ordinary pneumonic sputum, but contained more blood colouring matter. 5 p.m.—Temp. 104°. Pulse 130. Respiration 35. **31.12.98.**—7 a.m.—Temp. 103·6°. Pulse 148. Respiration 48. 9.30 a.m.—Temp. 104°. Pulse 44. Respiration 56. No sputum brought up. 20 *c.c. inoculated* 11 a.m.—Temp. 101·6°. Pulse running.



CASE No. XXII. (Admitted on 2nd day of the disease.)

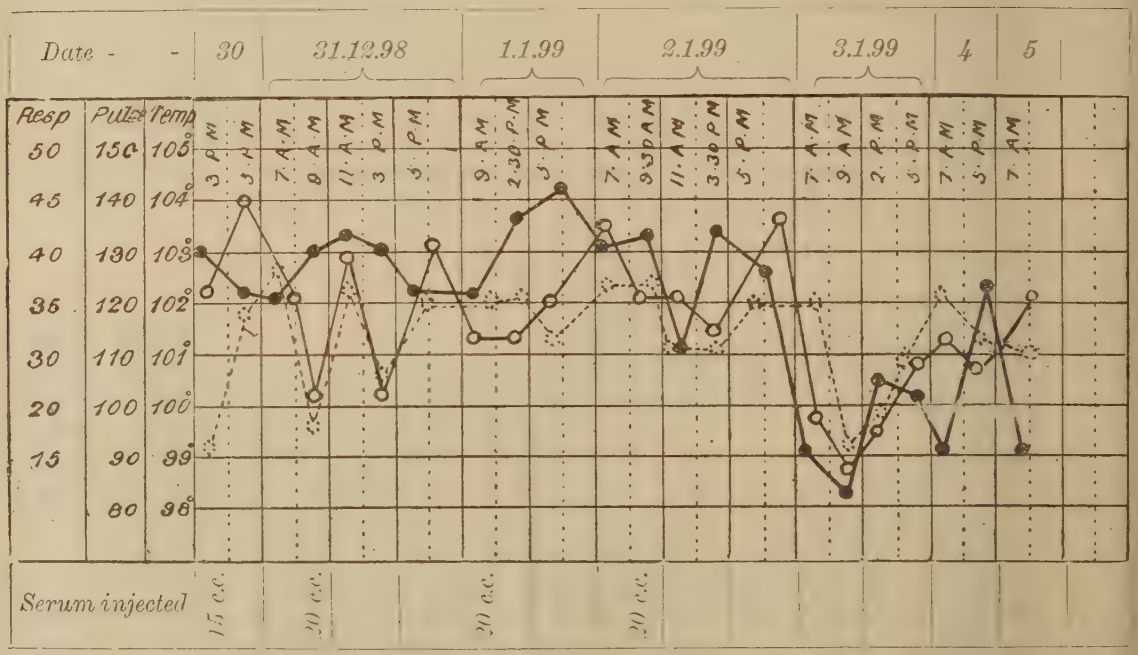


Ummanee. Age 11. Female. Admitted **30.12.98.**—2 p.m. Fever came on yesterday. Bubo appeared during the night. Temperature 105·4°. Pulse 152. Respiration 28. 3 p.m.—Very dull and apathetic. Heart and lungs clear. Tongue could not be seen. Bubo in left axilla. No wound. 15 *c.c. inoculated.* 5 p.m.—Temp. 104·2°. Pulse 154. Respiration 28. **31.12.98.**—7 a.m.—Temp. 104. Pulse 144. Respiration 36. 9 a.m.—Temp. 104°. Pulse 128. Respiration 36. 20 *c.c. inoculated.* 11 a.m.—Temp. 104°. Pulse 144. Respiration 36. 2 p.m.—Temp. 102·8°. Pulse 136. Respiration 36. 3 p.m.—Temp. 103·2°. Pulse 132. Respiration 40. 5 p.m.—Temp. 103°. Pulse 156. Respiration 42. **1.1.99.**—9 a.m.—Temp. 103·6°. Pulse 120. Respiration 44. 20 *c.c. inoculated.* 2 p.m.—Temp. 104. Pulse 132. Respiration 40. 5 p.m.—Temp. 104. Pulse 170. Respiration 42.

CASE No. XXIII. (Admitted on 5th day of the disease.)

Janakiammah. Age 13. Female. Admitted **30.12.98.**—2 p.m. Four days ago fever and bubo. 3 p.m.—General condition bad. Very restless and delirious. Bubo beneath left sterno mastoid. Tongue furred, white and dry. Tonsil could not be seen. Heart and lungs clear. Temp. 103·8°. Pulse 128. Respiration 36. 20 *c.c. inoculated* after much struggling. 5 p.m.—Temp. 104°. Pulse 144. Respiration 35. **31.12.98.**—7 a.m.—Temp. 101°. Pulse 104. Respiration 32. 9 a.m.—Temp. 101·4°. Pulse 136.—Respiration 36. General condition very bad. 20 *c.c. inoculated.* Very delirious; quieter. Pulse very weak. 11 a.m.—Temp. 102·4°. Pulse 100. Respiration 32. 2 p.m.—Temp. 104·4°. Pulse 132. Respiration 44. 3 p.m.—Very delirious, trying to get out of bed. Temp. 104·8°. Pulse 120. Respiration 36. 30 grs. of Potassi. Bromid. ordered. 5 p.m.—Temp. 105°. Pulse 148. Respiration 46.

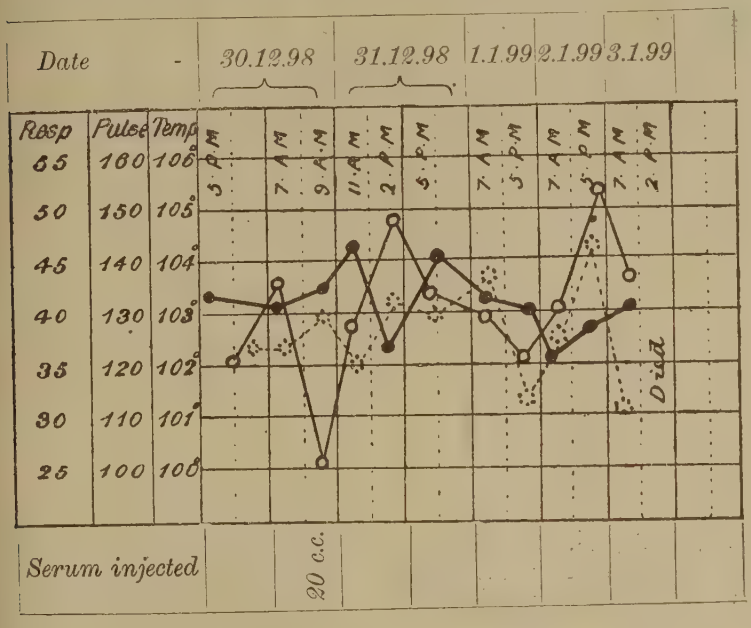
CASE No. XXIV. (Admitted on 2nd day of the disease.)



Munanee Amal. Aged 9. Fever. Sister of Case No. XXIII. Admitted **30.12.98.**—2 p.m. Fever for one day. 3 p.m.—Dull, apathetic. No bubo. Heart and lungs clear. Tongue, white fur. Temp. 103°. Pulse 122. Respiration 20. 15 *c.c. inoculated.* 5 p.m.—Temp. 102·4°. Pulse 140. Respiration 35 **31.12.98.**—7 a.m.—Temp. 102°. Pulse 120. Respiration 38. 9 a.m.—Temp. 103°. Pulse 104. Respiration 24. Bubo on right side of neck beneath the upper part of sterno mastoid. Tongue fairly clean. Still dull. 20 *c.c. inoculated.* 11 a.m.—Temp. 103·2°. Pulse 120. Respiration 36. 3 p.m.—Temp. 103°. Pulse 104. Respiration 28. Sensible. but dull. 5 p.m.—Temp. 102·4°. Pulse 132. Respiration 36. **1.1.99.**—9 a.m.—Temp. 102°. Pulse 116. Respiration 36. 20 *c.c. inoculated.* Seems better. Bubo in right axilla. 2.30 p.m.—Temp. 103·6°. Pulse 116. Respiration 36. Much brighter. 5 p.m.—Temp 104·2°. Pulse 120. Respiration 32. **2.1.99.**—7 a.m. Temp. 103°. Pulse 132. Respiration 36. 9.30 a.m.—Temp. 103·2°. Pulse 120. Respiration 36. Better. 20 *c.c. inoculated.* 11 a.m. Temp. 101°. Pulse 120. Respiration 30. 3.30 p.m.—Temp. 103·4°. Pulse 116. Respiration 30. Condition about the same. no worse. 5 p.m.—Temp. 102·8°. Pulse 136. Respiration 36. **3.1.99.**—7 a.m.—Temp. 99°. Pulse 98. Respiration 36. 9 a.m.—Temp. 98·4°. Pulse 88. Respiration 20. Not inoculated. 2 p.m.—Temp. 100·8°. Pulse 96. Respiration 24. 5 p.m.—Temp. 100·4°. Pulse 108. Respiration 20. **4.1.99.**—7 a.m.—Temp. 99. Pulse 112. Respiration 36. 5 p.m.—Temp. 102·4°. Pulse 108. Respiration 32. **5.1.99.**—7 a.m.—Temp. 99·2°. Pulse 120. Respiration 30.

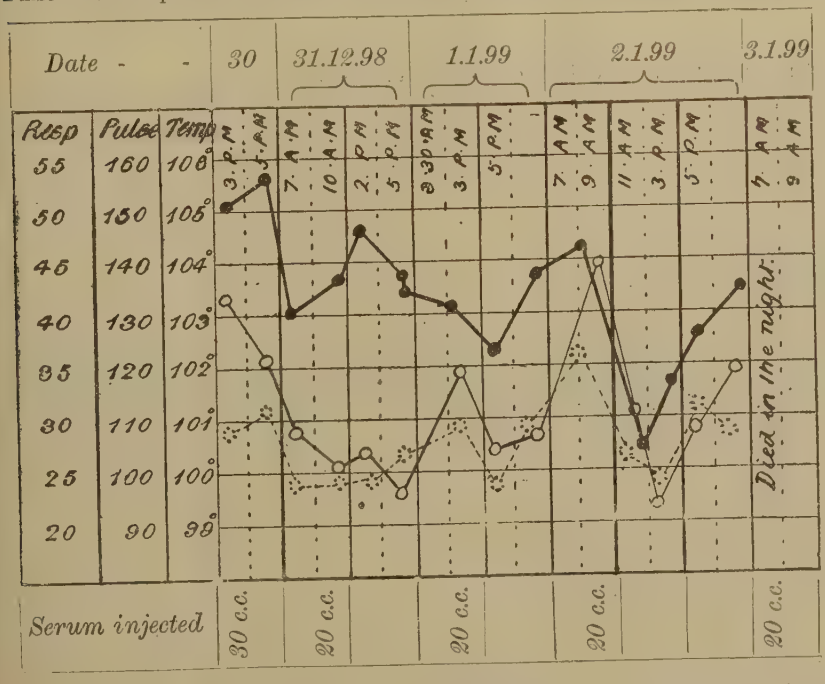
30.12.98.—Two other cases were admitted about this time, one a small child with a suppurating bubo, the other a man with a normal temperature, who complained of pains all over, which had been present for 10 days.

CASE No. XXV. (Admitted on 6th day of the disease.)



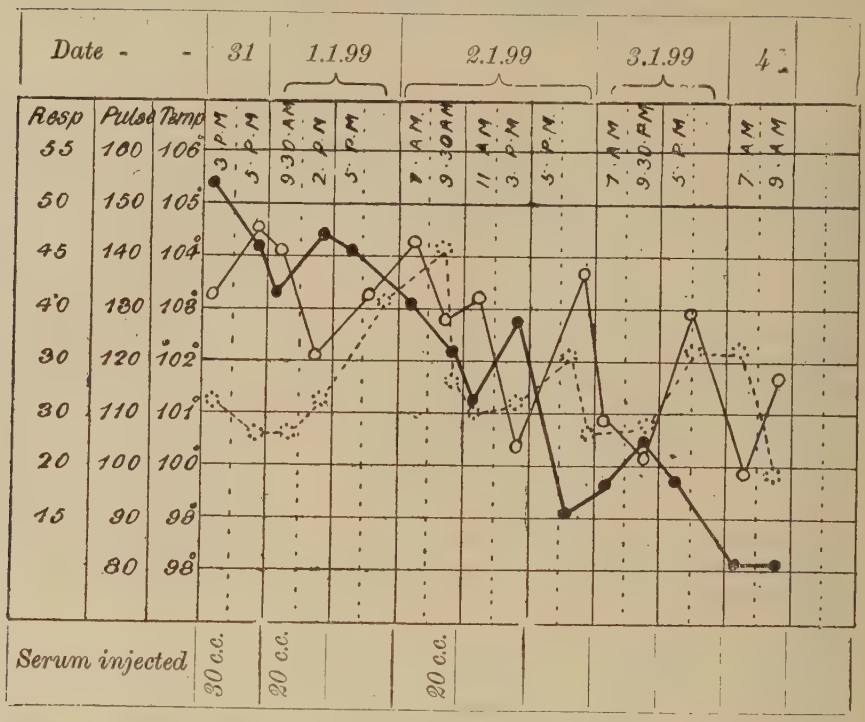
Santhiamal. Age 25. Female. Admitted **30.12.98.**—12 p.m. Illness for five days. 3 p.m.—Cold in the head. Heart normal. Râles, rhonchi, and whistling over both lungs. Most marked at left base. No sputum. 5 p.m.—Temperature 103·2°. Pulse 120 Respiration 36. **31.12.98.**—7 a.m.—Temp. 103°. Pulse 122. Respiration 36. 9 a.m.—Temp. 103·4°. Pulse 100. Respiration 40. 20 *c.c. inoculated.* 11 a.m.—Temp. 104·2°. Pulse 128. Respiration 34. 2 p.m.—Temp. 102·6°. Pulse 148. Respirations 42. 5 p.m.—Temp. 104. Pulse 136. Respiration 40. **1.1.99.**—7 a.m.—Temp. 103·2°. Pulse 130. Respiration 44. 5 p.m.—Temp. 103°. Pulse 120. Respiration 32. This case does not seem at all like a plague case, there being no marked symptoms of depression, not inoculated in consequence. **2.1.99.**—7 a.m.—Temp. 102°. Pulse 130. Respiration 36. 5 p.m.—Temp. 102·8°. Pulse 156. Respiration 46. Does not look very serious, pulse good, although fast; vomited a round worm. **3.1.99.**—7 a.m.—Temp. 103°. Pulse 132. Respiration 30. Still coughing, râles and rhonchi in lungs. Not so well.

CASE No. XXVI. (Admitted on 2nd day of the disease.)



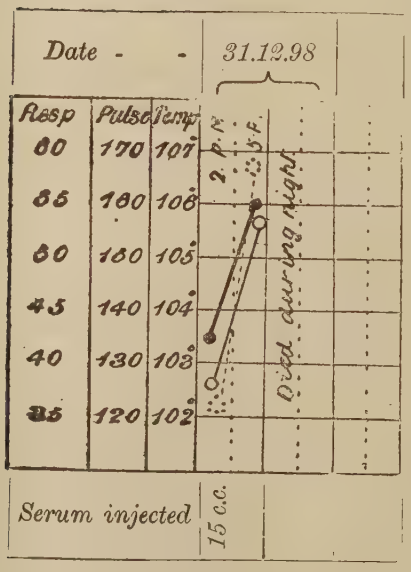
Chumappu. Age 27. Male. Admitted **30.12.98.**—1 p.m. Yesterday evening fever and bubo in left groin. 3 p.m.—Dull, quiet. Heart and lungs clear. Bubo in left groin. Tongue furred, white. Temperature 105. Pulse 132. Respiration 28. 30 *c.c. inoculated.* 5 p.m.—Temp. 105·6°. Pulse 120. Respiration 32. **31.12.98.**—7 a.m.—Temp. 103°. Pulse 108. Respiration 24. 10 a.m.—Temp. 103·8°. Pulse 100. Respiration 24. General condition improved. 20 *c.c. inoculated.* 11 a.m.—Temp. 103·8°. Pulse 94. Respiration 28. 2 p.m.—Temp. 104·8°. Pulse 104. Respiration 24. 3 p.m.—Temp. 103·6°. Pulse 96. Respiration 26. 5 p.m.—Temp. 103·2°. Pulse 120. Respiration 30. **1.1.99.**—8.30 a.m.—Temp. 102·6°. Pulse 104. Respiration 24. 20 *c.c. inoculated.* 3 p.m.—Temp. 103·8°. Pulse 108. Respiration 28. Very restless, has to be tied into bed. 5 p.m.—Temp. 104·2°. Pulse 140. Respiration 36. **2.1.99.**—7 a.m.—Temp. 100·2°. Pulse 110. Respiration 26. 9 a.m.—Temp. 101·6°. Pulse 92. Respiration 24. Much quieter, very weak, rapidly losing flesh. 20 *c.c. inoculated.* 11 a.m.—Temp. 102·6°. Pulse 108. Respiration 30. 3 p.m.—Temp 103·4°. Pulse 120. Respiration 28. Delirious, but not violent. **3.1.99.**—9 a.m.—Very bad, pulse not perceptible at the wrist. About 160. Respiration sighing, slow. Temp. 102°. 20 *c.c. inoculated.* 2 p.m.—Still living, but moribund.

CASE No. XXVIII. (Admitted on 4th day of the disease.)



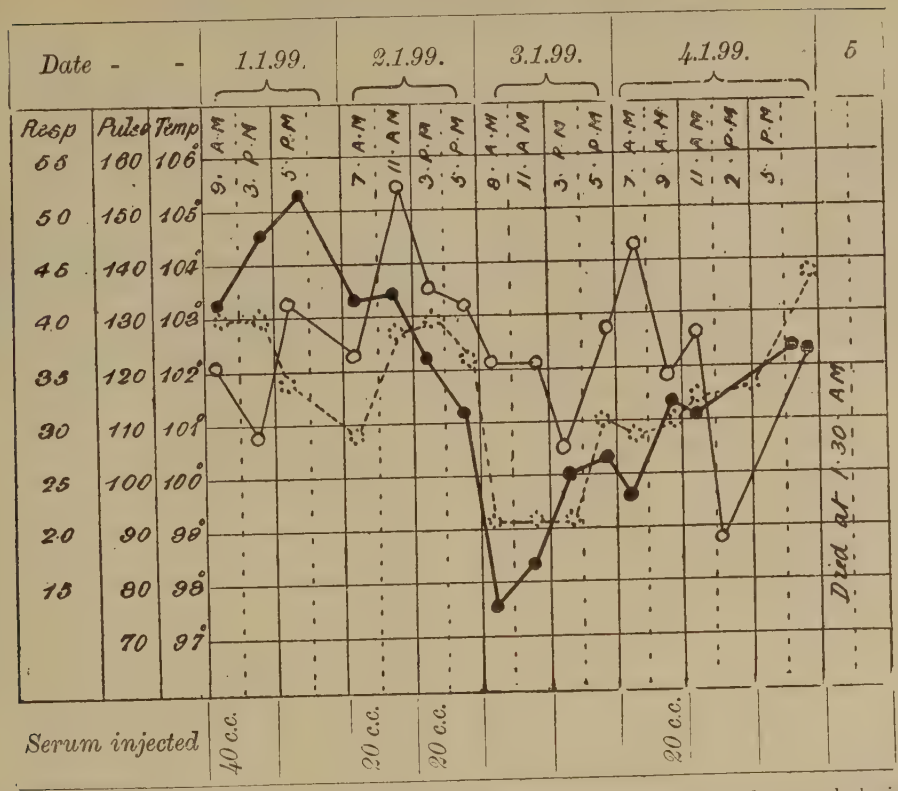
Ramabai. Age 25. Female. Admitted **31.12.98.**—1 p.m. Fever for three or four days. Bubo for two days. 3.0 p.m.—Tongue furred, white. General condition fair, but rather restless. Heart and lungs clear. Bubo in right axilla. Temp. 105·3°. Pulse 132. Respiration 32. 30 *c.c. inoculated.* 5.0 p.m.—Temp. 104·2. Pulse 144. Respiration 28. **1.1.99.**—9.30 a.m.—Temp. 103·2. Pulse 140. Respiration 28. Complains of much pain in bubo. 20 *c.c inoculated.* 2.0 p.m.—Temp. 104·4°. Pulse 120. Respiration 32. General condition very fair. 5.0 p.m.—Temp. 104°. Pulse 134. Respiration 42. Slightly delirious. **2.1.99.**—7.0 a.m.—Temp. 103°. Pulse 144. Respiration 48. 9.30 a.m.—Temp. 102·2°. Pulse 128. Respiration 34. General condition good; complains of much pain in the bubo. 20 *c.c. inoculated* (under protest). 11.0 a m.—Temp. 101·4°. Pulse 132. Respiration 32. 3.0 p.m.—Temp. 102·8°. Pulse 104. Respiration 32. Seems better. 5.0 p.m.—Temp. 99°. Pulse 136. Respiration 36. **3.1.99.**—7.0 a.m.—Temp. 99·8°. Pulse 108. Respiration 28. 9.30 a.m.—Temp. 100·4°. Pulse 104. Respiration 28. Not inoculated; much better; bubo still painful. 2.0 p.m.—Sleeping quietly. 5.0 p.m.—Temp. 99·8°. Pulse 130. Respiration 36. **4.1.99.**—7.0 a.m.—Temp. 98°. Pulse 98. Respiration 36. 9.0 a.m.—Temp. 98°. Pulse 116. Respiration 24.

CASE No. XXIX. (Admitted on ? day of the disease.)



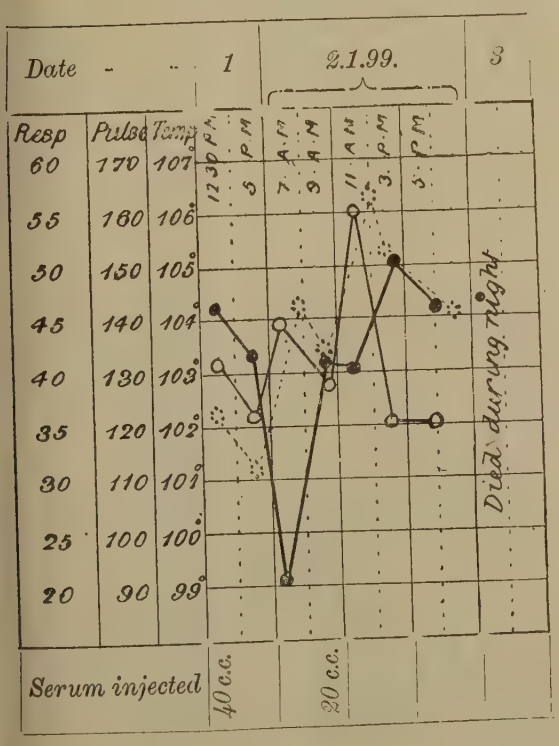
Kavariamah. Aged 2. Female. Admitted **31.12.98.**—10.30 a.m. History.—None. Temp. 103·2°. Pulse 124. Respiration 36. General condition bad, constantly shaking her head, and grinding teeth. 2.0 p.m.—15 *c.c. inoculated* into buttock. 5.0 p.m.—Temp. 106°. Pulse 156. Respiration 58.

CASE No. XXX. (Admitted on 5th day of the disease.)



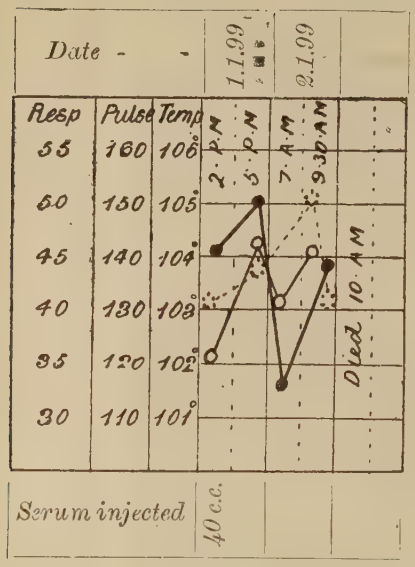
Kupram Rajoo. Aged. Male. Admitted **1.1.99.**—9 a.m. Fever for four days. Two days ago bubo in right groin. One day ago bubo on left side of the neck. General condition, very bad indeed. Pulse very weak and irregular, 120. Temperature 103·4°. Respiration 40. Never still, tendons at wrist continually twitching. Low muttering delirium. Might die at any time. 40 *c.c. injected.* 3 p.m.—Temp. 104·4°. Pulse 108. Respiration 40. Pulse stronger. 5 p.m.—Temp. 105·2°. Pulse 132. Respiration 34. **2.1.99.**—7 a.m.—Temp. 103·4. Pulse 122. Respiration 28. 9.30 a.m.—Rather better. 20 *c.c. inoculated.* 11 a.m.—Temp. 103·6°. Pulse 156. Respiration 38. 3 p.m.—Temp. 102·2°. Pulse 136. Respiration 40. Condition much the same; not sensible, but quiet. 20 *c.c. inoculated.* 5 p.m.—Temp. 101·2°. Pulse 132. Respiration 36. **3.1.99.**—8 a.m.—Temp. 97·8°. Pulse 120. Respiration 20. Very much better; pulse much stronger; patient exceedingly feeble. Not inoculated. 11 a.m.—Temp. 98·4°. Pulse 120. Respiration 20. 3 p.m.—Temp. 100°. Pulse 104. Respiration 20. Very weak, but sensible; pulse better. 5 p.m.—Temp. 100·2°. Pulse 128. Respiration 30. **4.1.99.**—7 a.m.—Temp. 99·6°. Pulse 144. Respiration 28. 9 a.m.—Temp. 101·6°. Pulse 108. Respiration 30. Not quite so well. 20 *c.c. inoculated.* 11 a.m.—Temp. 101°. Pulse 128. Respiration 32. 2 p.m.—Temp. 101·8. Pulse 88. Respiration 34. 5 p.m.—Temp. 102·4. Pulse 124. Respiration 44.

CASE No. XXXI. (Admitted on 6th day of the disease.)



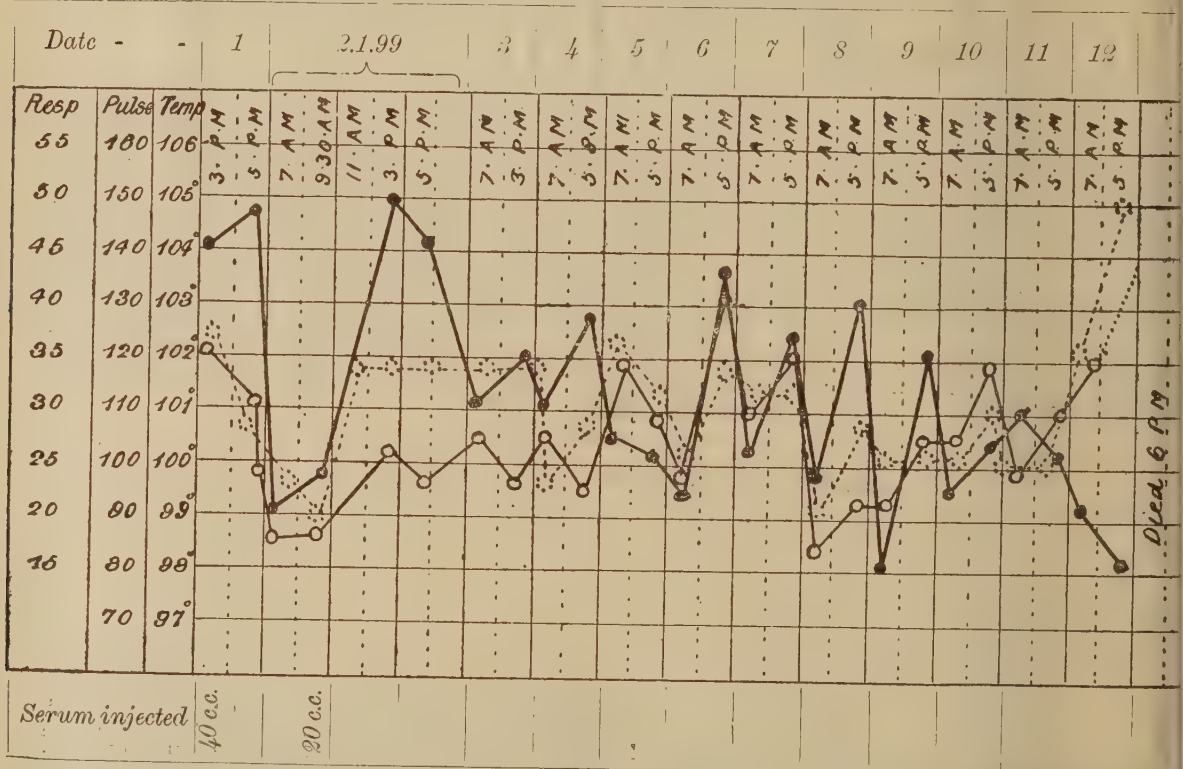
Mooniswamy. Age 18. Male. Admitted **1.1.99.**—12.30 p.m. Fever for three days. Cough for four days. Temperature 104·2°. Pulse 132. Respiration 36. 3 p.m.—General condition not good. Small wound on right forearm. Bubo in right epitrochlear glands. Lungs: Left lung diminished resonance, increased vocal vibrations, and bronchial breathing. Right lung practically normal; a few râles heard at base. 40 *c.c. inoculated.* 5 p.m.—Temp. 103·6°. Pulse 120. Respiration 30. **2.1.99.**—7 a.m.—Temp. 99°. Pulse 140. Respiration 46. 9 a.m.—Temp. 103·2°. Pulse 128. Respiration 42. Right lung involved in disease, marked bronchial breathing and coarse râles. No sputum obtained. 20 *c.c. inoculated.* 11 a.m.—Temp. 103°. Pulse 160. Respiration 56. 3 p.m.—Temp. 105·2°. Pulse 120. Respiration 52. Very bad. 5 p.m.—Temp. 104·2°. Pulse 120. Respiration 45.

CASE No. XXXII. (Admitted on 6th day of the disease.)



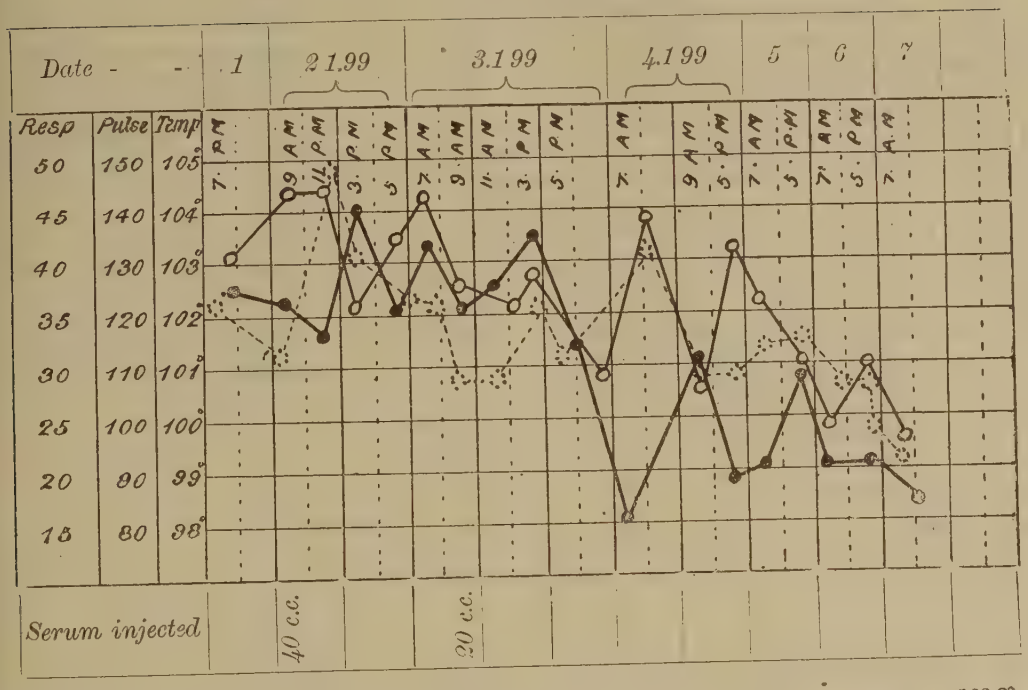
Thinakah. Age 35. Female. Admitted **1.1.99.** Fever for 5 days, and pain in left groin for the same time. 2 p.m.—General condition fair. Heart and lungs normal. 40 *c.c. inoculated.* Very small bubo in left femoral region. Temperature 104°. Pulse 120. Respiration 40. 5 p.m.—Temp. 105°. Pulse 144. Respiration 44. **2.1.99.**—7 a.m.—Temp. 101·6°. Pulse 130. Respiration 50. 9.30 a.m.—Temp. 103·8°. Pulse 140, not perceptible at the wrist. Respiration 40. Moribund.

CASE No. XXXIII. (Admitted on 1st day of the disease.)



Perrinhavahma. Age 55. Mother of XXIII. and XXIV. Admitted 3 p.m.—**1.1.99.** Has been nursing her children in hospital. This afternoon vomited twice, no rigor. Complains of headache. Tongue furred. No bubo or pain in site of any set of glands. Temperature 104°. Pulse 120. Respiration 36. 40 *c.c. inoculated.* 5 p.m.—Temp. 104·6°. Pulse 110. Respiration 28. **2.1.99.**—7 a.m.—Temp. 99°. Pulse 88. Respiration 24. 9.30 a.m.—Temp. 99·8°. Pulse 88. Respiration 20. 20 *c.c. inoculated.* 11 a.m.—Temp. 102·6°. Pulse 96. Respiration 36. 3 p.m.—Temp. 105°. Pulse 104. Respiration 36. No bubo. 5 p.m.—Temp. 104·2°. Pulse 98. Respiration 36. **3.1.99.**—7 a.m.—Temp. 101·2°. Pulse 108. Respiration 36. 5 p.m.—Temp. 102. Pulse 98. Respiration 36. **4.1.99.**—7 a.m.—Temp. 101°. Pulse 108. Respiration 24. 5 p.m.—Temp. 102·8°. Pulse 98. Respiration 28. **5.1.99.**—7 a.m.—Temp. 100·8°. Pulse 120. Respiration 36. Feels quite well. 5 p.m.—Temp. 100°. Pulse 108. Respiration 32. **6.1.99.**—7 a.m.—Temp. 99·4°. Pulse 96. Respiration 26. 5 p.m.—Temp. 103·8°. Pulse 132. Respiration 35. **7.1.99.**—7 a.m.—Temp. 100·2°. Pulse 108. Respiration 30. 5 p.m.—Temp. 102·6°. Pulse 120. Respiration 32. **8.1.99.**—7 a.m.—Temp. 99·8°. Pulse 84. Respiration 22. 5 p.m.—Temp. 103°. Pulse 96. Respiration 28. **9.1.99.**—7 a.m.—Temp. 98°. Pulse 96. Respiration 25. 5 p.m.—Temp. 102·2°. Pulse 108. Respiration 26. **10.1.99.**—7 a.m.—Temp. 99·6°. Pulse 108. Respiration 26. 5 p.m.—Temp. 100·2°. Pulse 120. Respiration 30. **11.1.99.**—7 a.m.—Temp. 101°. Pulse 96. Respiration 25. 5 p.m.—Temp. 100·2°. Pulse 110. Respiration 25. **12.1.99.**—7 a.m.—Temp. 99·2°. Pulse 120. Respiration 30. From the 5th to this date, although patient had had some fever every night, she always stated that she felt quite well. Quinine had been administered, but in no way affected the temperature. When seen at 9 a.m., patient was breathing rapidly and laboriously, râles and rhonchi were heard over both lungs; in the afternoon patient's condition was much worse, she was, however, quite conscious, dulness was not complete on percussing the chest. 5 p.m.—Temp. 98·2. Pulse running. Respiration 50. No sputum could be obtained.

CASE No. XXXIV. (Admitted on 4th day of the disease.)

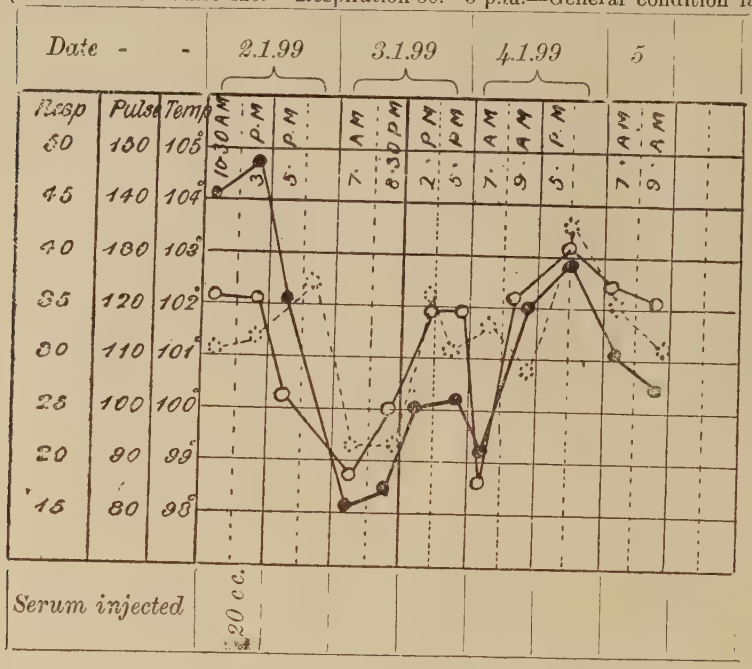


Runga. Age 14. Male. Admitted **1.1.99.** evening. Ill for three or four days. Temperature 102·8°. Pulse 130. Respiration 36. **2.1.99.**—7 a.m.—Temp. 102·4°. Pulse 144. Respiration 32. General condition fair. Heart and lungs normal. No bubo found. 40 *c.c. inoculated.* 11 a.m.—Temp. 101·6°. Pulse 144. Respiration 48. 3 p.m.—Temp. 104°. Pulse 120. Respiration 40. Complains of a pain in the belly. ? inoculation. 5 p.m. —Temp. 102°. Pulse 136. Respiration 36. **3.1.99.**—7 a.m.—Temp. 103·4°. Pulse 144. Respiration 36. 9 a.m. —Temp. 102°. Pulse 120. Respiration 28. 20 *c.c. inoculated.* No bubo. Slight cough. Sputum mucopus. 11 a.m.—Temp. 102·6°. Pulse 120. Respiration 28. 2.30 p.m.—Temp. 103·4°. Pulse 128. Respiration 36. General condition good. 5 p.m.—Temp. 101·2°. Pulse 108. Respiration 32. **4.1.99.**—7 a.m.—Temp. 98°. Pulse 136? Respiration 42. 9 a.m.—Temp. 101·2°. Pulse 116. Respiration 28. 5 p.m.—Temp. 98·8°. Pulse 132. Respiration 28. 5.1.99.—7 a.m.—Temp. 99°. Pulse 122. Respiration 32 5 p.m.—Temp. 100·8°. Pulse 108. Respiration 32. **6.1.99.**—7 a.m.—Temp. 99°. Pulse 93. Respiration 26. 5 p.m.—Temp. 99°. Pulse 110. Respiration 28. **7.1.99.**—7 a.m.—Temp. 98·4°. Pulse 96. Respiration 24.

1.1.99.—Two other cases admitted. One had had an abortion four days ago, and now had a slight temperature. The other was a very old woman, who had no bubo, and nothing to indicate plague in any way. Died.

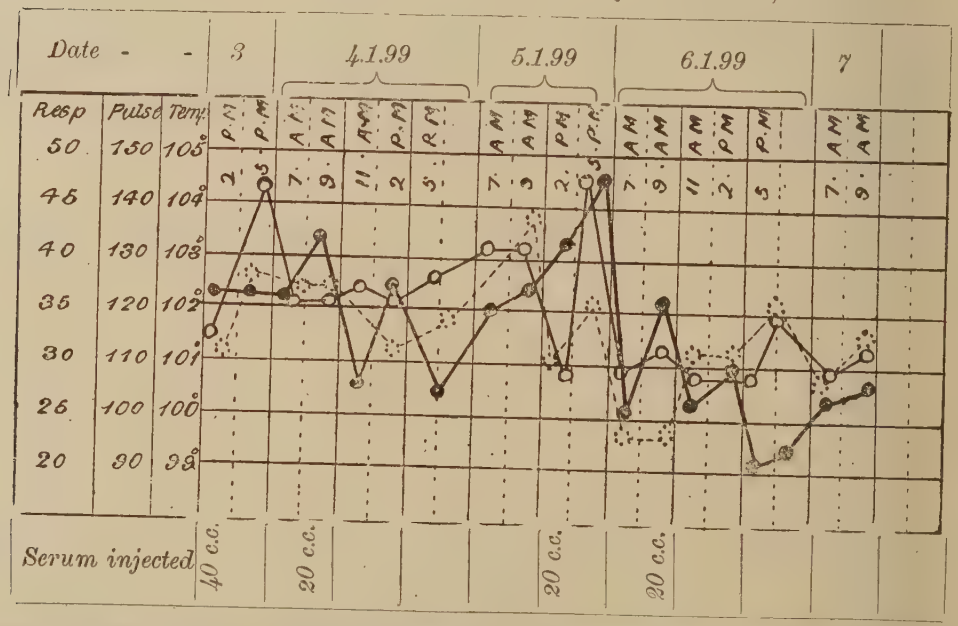
CASE No. XXXV. (Admitted on 3rd day of the disease.)

Ramalingam. Age 19. Admitted **2.1.99.**—10.30 a.m. Fever for two days. Bubo for one day. Temperature 104°. Pulse 120. Respiration 30. 3 p.m.—General condition fair. Tongue furred. Bubo in right groin. No wound found. Temperature 104·8°. Pulse 120. Respiration 32. 20 *c.c. inoculat* 5 p.m.—Temp. 102°. Pulse 1 Respiration 36. **3.1.99.**—7 a.m. Temp. 98°. Pulse 88. Respiration 8.30 a.m.—Temp. 98·4°. Pulse 1 Respiration 22. Much better. Bu in left axilla. 2 p.m.—Temp. 10 Pulse 120. Respiration 36. 5 p. —Temp. 100°. Pulse 120. Respir tion 30. **4.1.99.**—7 a.m.—Tem 99·2°. Pulse 88. Respiration 3 9 a.m.—Temp. 102°. Pulse 12 Respiration 28. Buboes very painf 5 p.m.—Temp. 103°. Pulse 1 Respiration 42. **5.1.99.**—7 a.m. Temp. 101°. Pulse 124. Respirati 35. 9 a.m.—Temp. 100·8°. Pulse 12 Respiration 30. **6.1.99.**—Remove to another ward to have the bubo opened.



2.1.99.—One case admitted with suppurating bubo in the morning and one in the afternoon.

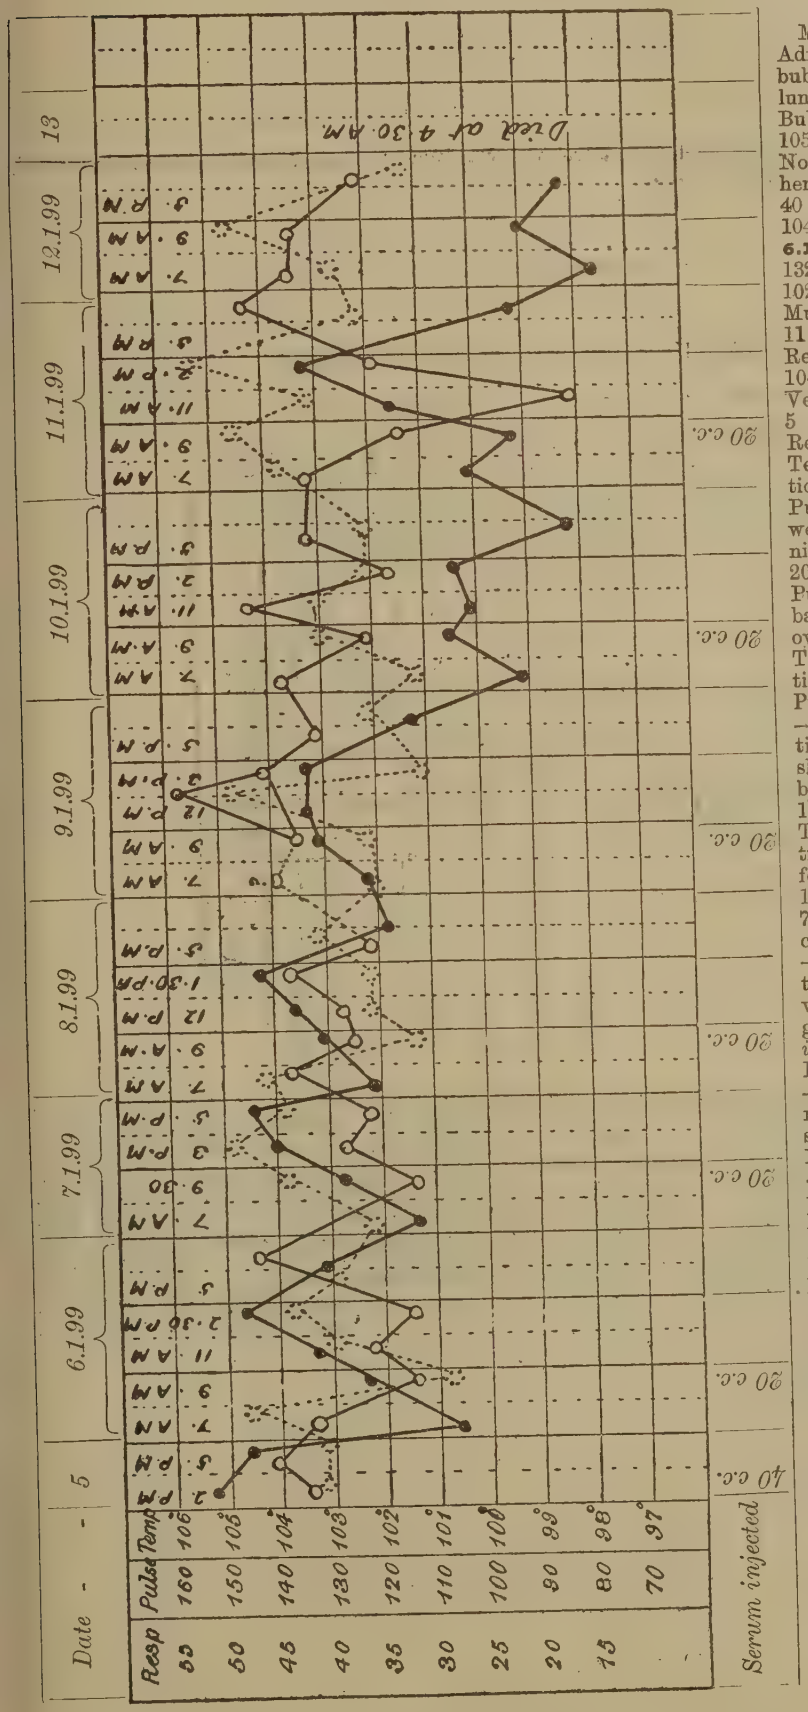
CASE No. XXXVI. (Admitted on 7th day of the disease.)



Mersamah. Age 25. Female. Admitted **3.1.99.**—2 p.m. Fever and bubo for six days. General condition fair; somewhat dull, and slightly delirious. Heart normal. Lungs: a few squeaks heard in both. Bubo in left groin. Temperature 102·2°. Pulse 114. Respiration 32. 40 *c.c. inoculated.* 5 p.m.—Temp. 102·2°. Pulse 144. Respiration 36. **4.1.99.**—7 a.m.—Temp. 102°. Pulse 120. Respiration 36. 9 a.m.—Temp. 103·4°. Pulse 120. Respiration 36. 20 *c.c. inoculated.* General condition a little worse, still slightly delirious. 11 a.m.—Temp. 100·6°. Pulse 124. Respiration 32. 2 p.m.—Temp. 102·6. Pulse 120. Respiration 40. Delirious. Bronchial breathing (modified) over the front of right lung, but resonance fair, although diminished. 5 p.m.—Temp. 100·6°. Pulse 126. Respiration 34. **5.1.99.**—7 a.m.—Temp. 102. Pulse 132. Respiration 40. 9 a.m.—Temp. 102·2°. Pulse 132. Respiration 44. 2 p.m.—Temp. 103·2°. Pulse 108. Respiration 32. 20 *c.c. serum.* 5 p.m.—Temp. 104·8. Pulse 144. Respiration 36. **6.1.99.**—7 a.m.—Temp. 100°. Pulse 108. Respiration 24. 9 a.m.—Temp. 102·2°. Pulse 112. Respiration 24. 20 *c.c. inoculated.* Lungs clear; breathing more natural. 11 a.m.—Temp. 100·2°. Pulse 108. Respirations 32. 2 p.m.—Temperature 101°. Pulse 108. Respiration 30. Complains of pain on swallowing. 5 p.m.—Temperature 99·2°. Pulse 120. Respiration 36. **7.1.99.**—7 a.m.—Temp. 100·4°. Pulse 108. Respiration 28. 9 a.m.—Temp. 100·6°. Pulse 112. Respiration 32.

5.1.99.—One case admitted suffering from a diffuse swelling of the whole thigh (left), removed to another hospital.

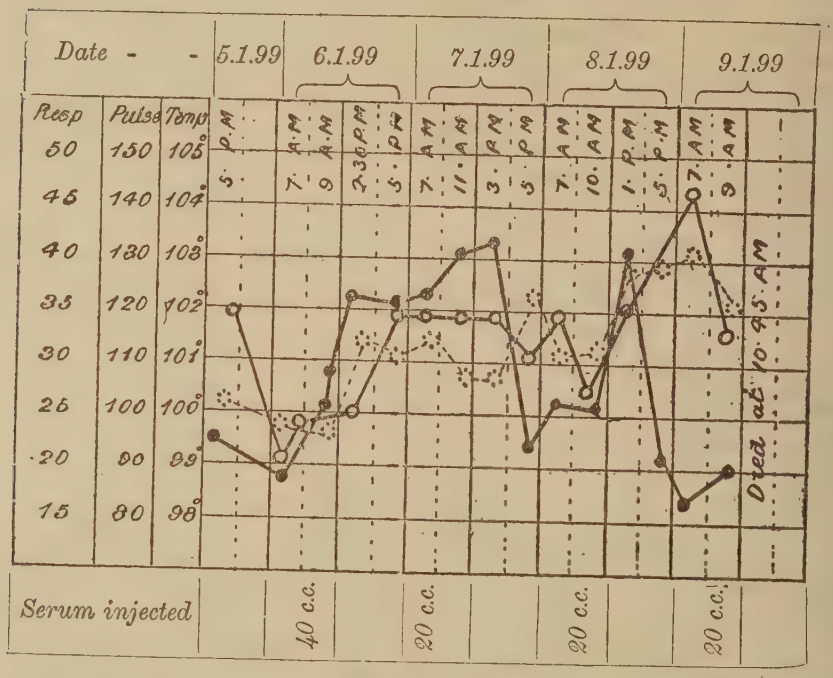
CASE No. XXXVII. (Admitted on 4th day of the disease.)



Mooniamah. Age 30. Female. Admitted **5.1.99.**—1 p.m. Fever and bubo for 3 days. 2 p.m.—Heart and lungs normal. General condition fair. Bubo in left groin. Temperature 105·2°. Pulse 132. Respiration 42. No wound, but states that she hurt her foot with a nail 3 or 4 days ago. 40 *c.c. inoculated.* 5 p.m.—Temp. 104·8°. Pulse 140. Respiration 40. **6.1.99.** 7 a.m.—Temp. 100·2°. Pulse 132. Respiration 48. 9 a.m.—Temp. 102·2°. Pulse 112. Respiration 28. Much better. 20 *c.c. inoculated.* 11 a.m.—Temp. 103·2°. Pulse 124. Respiration 40. 2.30 p.m.—Temp. 104·8°. Pulse 116. Respiration 44. Very delirious; condition worse. 5 p.m.—Temp. 103°. Pulse 144. Respiration 40. **7.1.99.**—7 a.m.—Temp. 101·2°. Pulse 122. Respiration 36. 9.30 a.m.—Temp. 102·8°. Pulse 112. Respiration 44. Pulse weak; very delirious during the night; now quiet, but very apathetic. 20 *c.c. serum.* 3 p.m.—Temp. 104°. Pulse 128. Respiration 48. Very bad. Lungs: sibilant râles heard over the front of both. 5 p.m.—Temp. 104·4°. Pulse 122. Respiration 44. **8.1.99.**—7 a.m.—Temp. 102°. Pulse 136. Respiration 45. 9 a.m.—Temp. 103°. Pulse 124. Respiration 32. 20 *c.c. serum.* Looks slightly better, but condition still bad. 12 p.m.—Temp. 103·6°. Pulse 126. Respiration 36. 1.30 p.m.—Temp. 104·2°. Pulse 136. Respiration 36. Condition very bad; pulse feeble. 5 p.m.—Temp. 101·8. Pulse 120. Respiration 42. **9.1.99.**—7 a.m.—Temp. 102°. Pulse (was uncountable). Respiration 35. 9 a.m.—Temp. 103°. Pulse 132. Respiration 36. Patient very wasted; pulse very bad. **9.1.99.**—Seems to be getting worse day by day. 20 *c.c. inoculated.* 12 p.m.—Temp. 103·2°. Pulse 156. Respiration 48. 3 p.m.—Temp. 103·2°. Pulse 140. Respiration 30. Very bad; pulse very small. 5 p.m.—Temp. 101·6°. Pulse 130. Respiration 36. **10.1.99.**—7 a.m.—Temp. 99°. Pulse 136. Respiration 30. 9 a.m.—Temp. 100·6°. Pulse 120. Respiration 40. Still exceeding weak. 20 *c.c. serum.* 11 a.m.—Temp. 100°. Pulse 144. Respiration 40. 2 p.m.—Temp. 100·2°. Pulse 116. Respiration 36. Pulse stronger; slightly better. 5 p.m.—Temp. 98·2°. Pulse 132. Respiration 36. **11.1.99.**—7 a.m.—Temp. 100°. Pulse 132. Respiration 44. 9 a.m.—Temp. 99·4°. Pulse 116. Respiration 48. Lungs: many râles. 20 *c.c. serum.* 11 a.m.—Temp. 101·6°. Pulse 80. Respiration 40. 2 p.m.—Temp. 103·2. Pulse 120. Respiration 52. 5 p.m.—Temp. 99·2°. Pulse 144. Respiration 36. **12.1.99.**—7 a.m.—Temp. 97·6°. Pulse 132. Respiration 38. 9 a.m.—Temp. 99°. Pulse 132. Respiration 48. 5 p.m.—Temp. 98·2°. Pulse 120. Respiration 32.

5.1.99.—One case admitted with normal temperature, who was found in a street seeming insensible, he had, however, drunk an unknown quantity of alcohol.

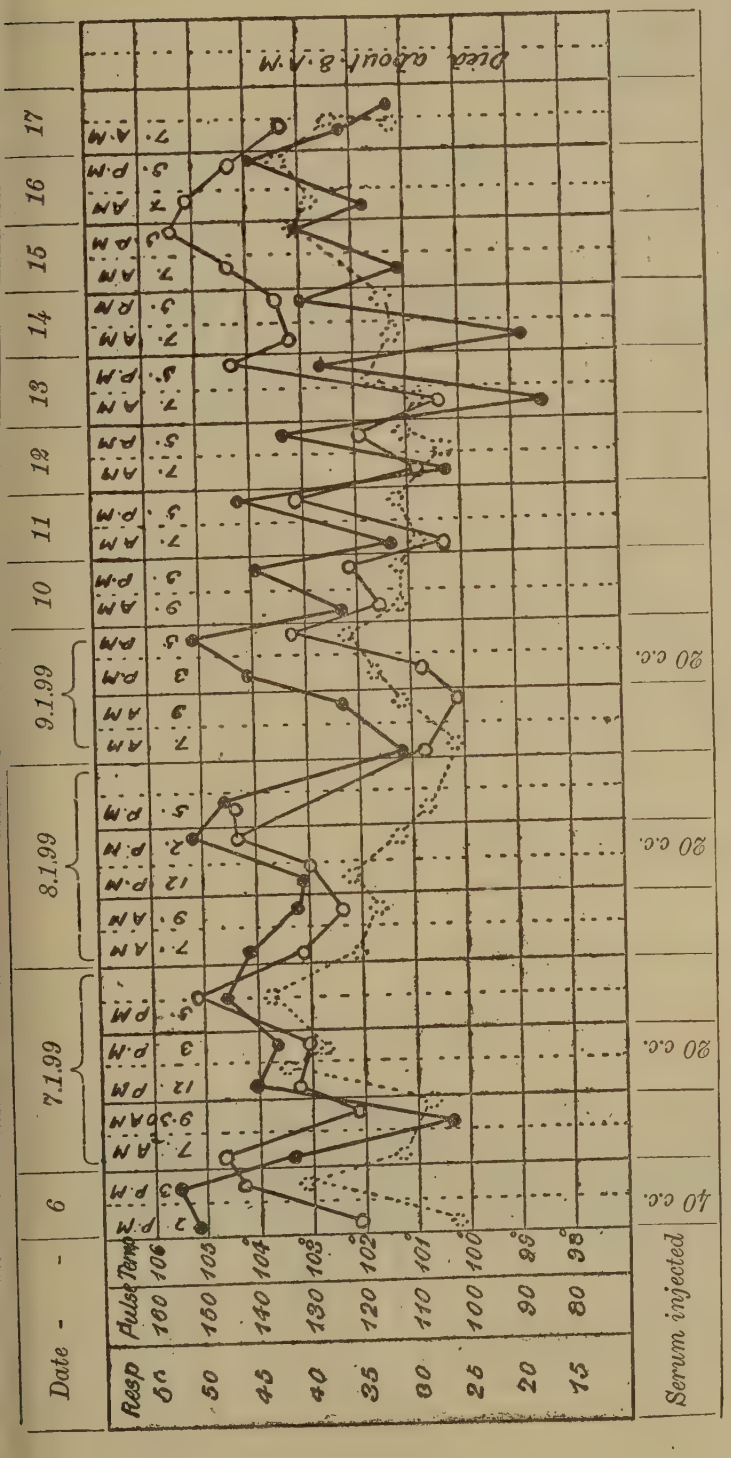
Case No. XXXVIII. (Admitted on 1st day of the disease.)



Anthony. Age 60. Male. Admitted **5.1.99.**—4 p.m. Taken ill yesterday (day of admission). Pain in the groin came on last night (5 and 6). Temp. 99·4°. Pulse 120. Respiration 26. **6.1.99.**—7 a.m.—Temp. 98·8°. Pulse 90. Respiration 24. 9 a.m.—Temp. 100·8°. Pulse 96. Respiration 24. A small painful bubo in left groin. Heart and lungs clear. Tongue very foul fur. General condition good. 40 *c.c. inoculated.* 2.20 p.m. —Temp. 102·6°. Pulse 100. Respiration 32. Some headache. 5 p.m.—Temp. 102·2°. Pulse 120. Respiration 30. **7.1.99.**—7 a.m.—Temp. 102·2°. Pulse 120. Respiration 32. 9 a.m.—20 *c.c. inoculated.* 11 a.m.—Temp. 103°. Pulse 120. Respiration 28. 3 p.m.—Temp. 103·2°. Pulse 120. Respiration 28. General condition fair. 5 p.m.—Temp. 99·4°. Pulse 110. Respiration 36. **8.1.99.**—7 a.m.—Temp. 100·4°. Pulse 120. Respiration 30. 10 a.m.—Temp. 100·2°. Pulse 104. Respiration 34. 1 p.m.—Temp. 103·2°. Pulse 120. Respiration 38. 20 *c.c. serum.* 5 p.m.—Temp. 99·2°. Pulse 128. Respiration 40. **9.1.99.**—7 a.m.—Temp. 98·4°. Pulse 144. Respiration 42. 9 a.m.—Condition very bad, extremely weak, pulse very small. Temp. 99°. Pulse 116. Respiration 36. 20 *c.c. serum.*

6.1.99.—One case of tetanus admitted, but transferred to another hospital.

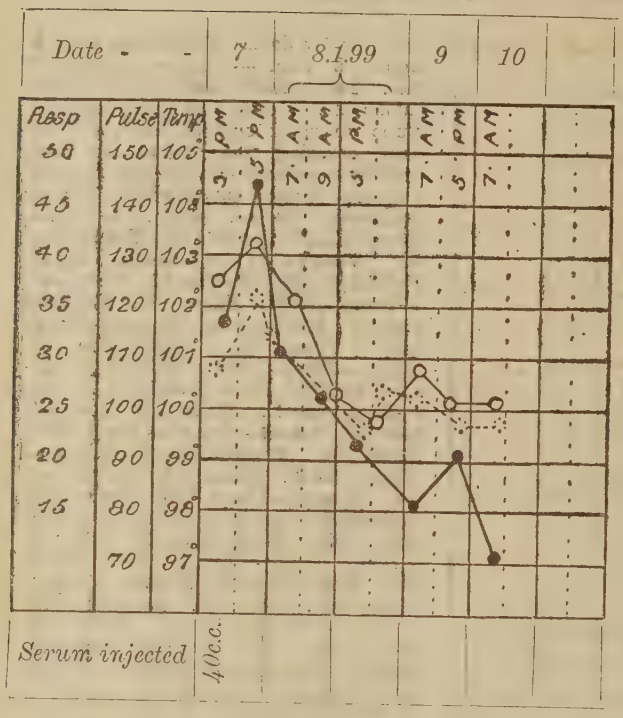
Case No. XXXIX. (Admitted on 6th day of the disease.)



Soomana. Aged 15. Female. Admitted **6.1.99.**—1 p.m. Pain in the neck for five days. Fever came on last night. 2 p.m. — General condition fair. Temp. 105°. Pulse 120. Respiration 26. Heart and lungs normal. Bubo on right side of neck, on the skin covering the bubo are four vesicles somewhat like 4th day vaccinia vesicles. Tongue furred white. Fauces reddened. 40 *c.c. serum.* 5 p.m.—Temp. 105·2°. Pulse 144. Respiration 40. **7.1.99.**—7 a.m.—Temp. 103.4°. Pulse 148. Respiration 32. 9.30. a.m. —Temp. 100·6°. Pulse 120. Respiration 28. Much better. 12 p.m.—Temp. 104°. Pulse 132. Respiration 42. 3 p.m.—Temp. 103·8°. Pulse 120. Respiration 38. 20 *c.c. inoculated.* 5 p.m. —Temp. 104·4°. Pulse 150. Respiration 44. **8.1.99.**—7 a.m.—Temp. 104°. Pulse 130. Respiration 35. 9 a.m.—Temp. 103·2°. Pulse 124. Respiration 34. 12 p.m.—Temp. 103°. Pulse 130. Respiration 36. 2 p.m.—Temp. 105·2°. Pulse 144. Respiration 32. 20 *c.c. serum.* 5 p.m.—Temp. 104·6°. Pulse 144. Respiration 28. **9.1.99.**—7 a.m.—Temp 101°. Pulse 108. Respiration 26. 9 a.m. — Temp. 102·2°. Pulse 100. Respiration 32. General condition better. Bubo extends from the middle line of the neck and fills up the whole of the submaxillary region. 3 p.m.—Temp. 104°. Pulse 108. Respiration 34. 20 *c.c. serum.* 5 p.m.—Temp. 105·2°. Pulse 132. Respiration 36. **10.1.99.**—9 a.m.—Temp. 102·2°. Pulse 116. Respiration 32. Bubo softening and showing signs of suppuration. Removed to another ward to have it opened. Bubo opened freely but no pus let out. 5 p.m.—Temp. 104°. Pulse 122. Respiration 32. **11.1.99.**—7 a.m. —Temp. 101·4°. Pulse 104. Respiration 28. 5 p.m.—Temp. 104·2°. Pulse 132. Respiration 32. **12.1.99.**—7 a.m. Temp. 100·2°. Pulse 108. Respiration 26. 5 p.m.—Temp. 103·4°. Pulse 120. Respiration 32. **13.1.99.**—7 a.m.—Temp. 98·4°. Pulse 104. Respiration 28. 5 p.m.—Temp. 102·8°. Pulse 144. Respiration 34. **14.1.99.**—7 a.m.—Temp. 98·8°. Pulse 132. Respiration 32. 5 p.m.—Temp. 103°. Pulse 134. Respiration 34. **15.1.99.**—7 a.m.—Temp. 101°. Pulse 144. Respiration 36. 5 p.m.—Temp. 103°. Pulse 156. Respiration 40. **16.1.99.**—7 a.m.—Temp. 101·8°. Pulse 152. Respiration 38. 5 p.m.—Temp. 104°.—Pulse 144. Respiration 42. **17.1.99.**—7 a.m.—Temp. 101·6°. Pulse 132. Respiration 36. On **16.1.99.** patient suddenly became much worse the breathing becoming laboured, signs of pneumonia rapidly developed, and she died on the morning of **17.1.99.**

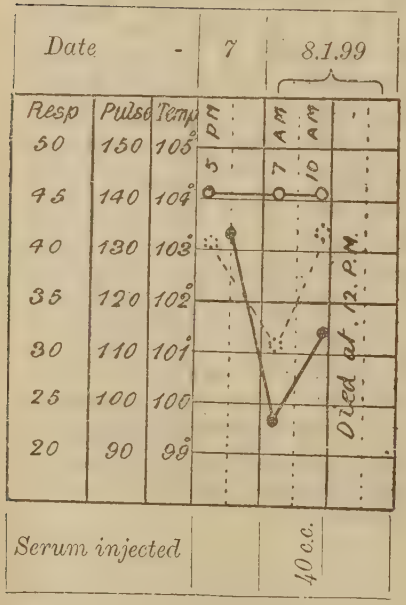
7.1.99.—One case admitted, ? acute rheumatism.

CASE No. XL. (Admitted on 4th day of the disease.)



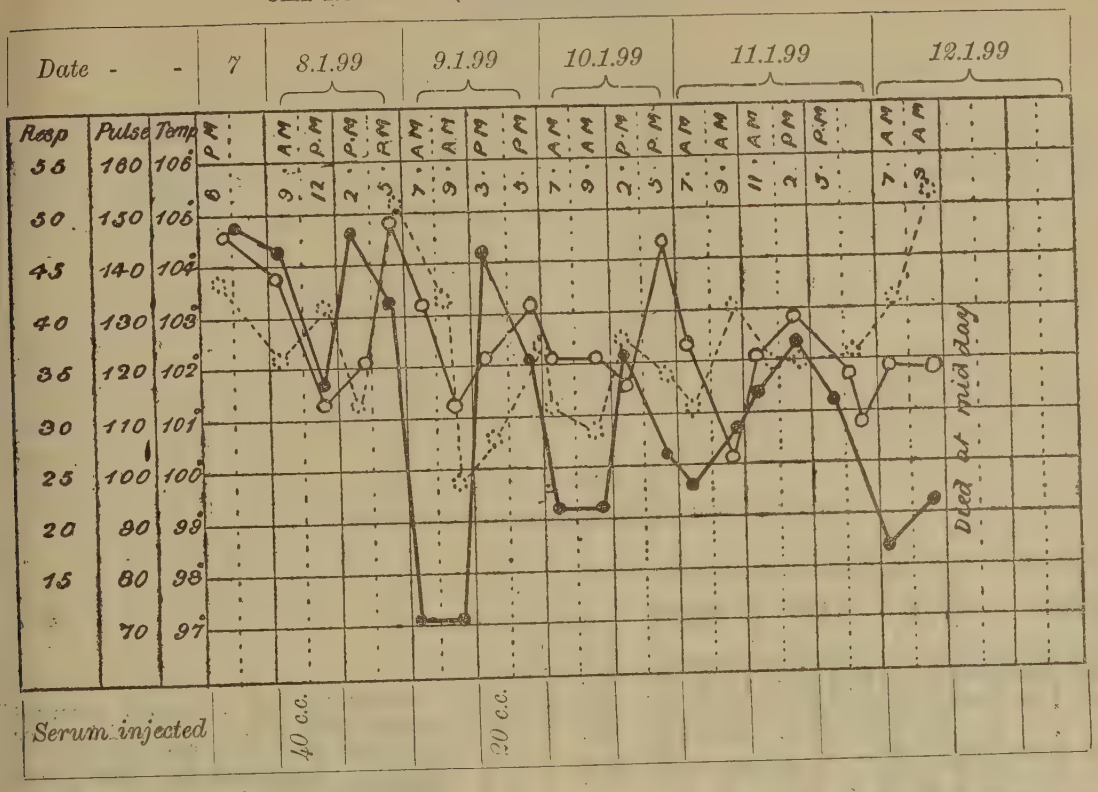
Venketamah. Age 20. Female. Admitted **7.1.99.**—11.30 a.m. Three days fever, two days bubo. 3.0 p.m.—General condition fair. Heart and lungs clear. Bubo in left axilla. Temperature 101·6°. Pulse 124. Respiration 28. 40 *c.c. inoculated.* 5.0 p.m.—Temp. 104·4°. Pulse 132. Respiration 36. **8.1.99.**—7.0 a.m.—Temp. 101°. Pulse 120. Respiration 32. 9.0 a.m.—Temp. 100·2°. Pulse 100. Respiration 28. Very much better. 5.0 p.m.—Temp. 99·2°. Pulse 98. Respiration 24. **9.1.99.**—7.0 a.m.—Temp. 98°. Pulse 108. Respiration 26. Feels quite well. 5.0 p.m.—Temp. 99·2°. Pulse 98. Respiration 24. **10.1.99.**—7.0 a.m.—Temp. 97°. Pulse 98. Respiration 24.

CASE No. XLI. (Admitted on 4th day of the disease.)



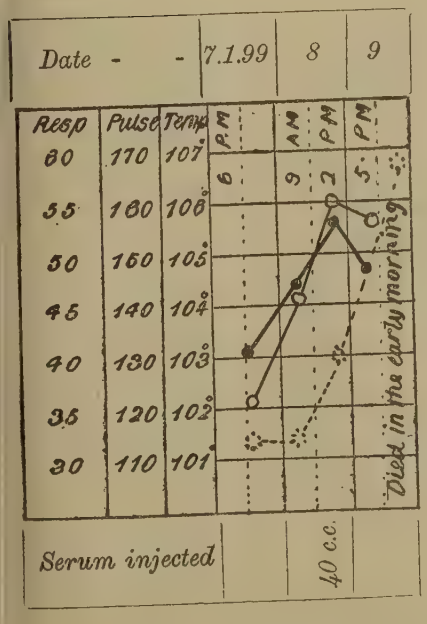
Annamaly. Age 50. Male. Admitted **7.1.99.**—5.0 p.m. Fever for three or four days. Temp. 103·4°. Pulse 140. Respiration 40. **8.1.99.**—7.0 a.m.—Temp. 99·8°. Pulse 140. Respiration 30. 10.0 a.m.—Very delirious. General condition very bad, moribund. Bubo in . Pulse very bad, 140. Respiration laboured, 44. Resonance over both lungs poor. Prolonged expiration heard over both lungs. Temp. 101·4°. 40 *c.c. inoculated.*

CASE No. XLII. (Admitted on 5th day of the disease.)



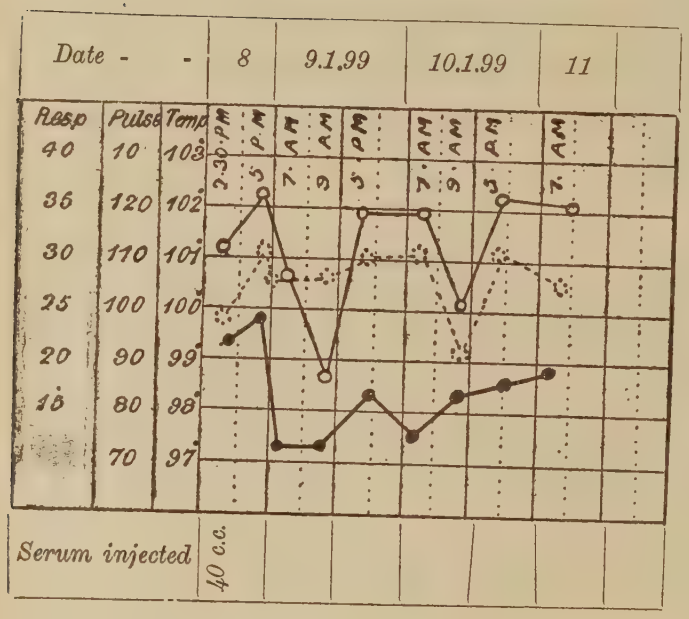
Pragasum. Age 35. Female. Admitted **7.1.99.**—6 p.m. Fever and bubo, four days. Temperature 104·8°. Pulse 148. Respiration 44. **8.1.99.**—9 a.m.—General condition indifferent. Heart and lungs normal. Bubo in right groin. Pregnant six months. Temp. 104·2°. Pulse 138. Respiration 36. 40 *c.c. serum.* 12 p.m.—Temp. 101·6°. Pulse 112. Respiration 42. 2 p.m.—Temp. 104·6°. Pulse 120. Respiration 32. 5 p.m.—Temp. 103·4°. Pulse 146. Respiration 50. **9.1.99.**—7 a.m.—Temp. 97°. Pulse 132. Respiration 42. 9 a.m.—Temp. 97. Pulse 112. Respiration 24. 3 p.m.—Temp. 104·2°. Pulse 120. Respiration 28. 20 *c.c. serum*, 5 p.m. Temp. 102°. Pulse 132. Respiration 36. **10.1.99.**—7 a.m.—Temp. 99·2°. Pulse 120. Respiration 30. 9 a.m.—Temp. 99·2°. Pulse 120. Respiration 28. Aborted last night. Complains of much pain in the bubo. 2 p.m.—Temp. 102·2°. Pulse 116. Respiration 36. 5 p.m.—Temp. 100·4°. Pulse 144. Respiration 34. **11.1.99.**—7 a.m.—Temp. 99·8°. Pulse 122. Respiration 30. 9 a.m.—Temp. 100·6°. Pulse 100. Respiration 40. 11 a.m.—Temp. 101·2°. Pulse 120. Respiration 34. 2 p.m.—Temp. 102·4°. Pulse 128. Respiration 36. Condition not so good. 5 p.m.—Temp. 100·2°. Pulse 108. Respiration 36. **12.1.99.**—7 a.m.—Temp. 98·4°. Pulse 120. Respiration 42. 9 a.m.—Temp. 99·4°. Pulse 120. Respiration 52. Condition bad, breathing very rapid, laboured; nothing discovered in lungs.

CASE No. XLIII. (Admitted on 2nd day of the disease.)



Arokin. Age 20. Female. Admitted **7.1.99.**—6 p.m. Taken ill yesterday. No bubo noticed. Temperature 103°. Pulse 120. Respiration 32. **8.1.99.**—9 a.m.—General condition indifferent. Heart and lungs normal. Tongue furred white, papillae very prominent. No spleen could be felt. Temp. 104·6°. Pulse 140. Respiration 32. 2.30 p.m.—Temp. 105·6°. Pulse 160. Respiration 40. General condition worse. Pulse small. Tenderness and slight enlargement of right cervical glands. 40 *c.c. of serum.* 5 p.m.—Temp. 104·8°. Pulse 156. Respiration 58.

CASE No. XLIV. (Admitted on 3rd day of the disease.)



Sodambah. Age . Female. Admitted **8.1.99.**—10.30 a.m. Fever and bubo for three days. 2.30 p.m.—Temperature 99·4°. Pulse 112. Respiration 24. General condition good. Bubo in right axilla. Heart and lungs normal. 40 *c.c. of serum.* 5 p.m. —Temp. 99·8°. Pulse 122. Respiration 32. **9.1.99.**—7 a.m.—Temp. 97·4°. Pulse 108. Respiration 28. 9 a.m.—Temp. 97·4°. Pulse 88. Respiration 28. Feels quite well. 5 p.m.—Temp. 98·4°. Pulse 120. Respiration 30. **10.1.99.**—7 a.m.—Temp. 97·6°. Pulse 120. Respiration 30. 9 a.m.—Temp. 98·4°. Pulse 100. Respiration 20. 5 p.m. —Temp. 98·6°. Pulse 124. Respiration 32. **11.1.99.**—7 a.m.—Temp. 98·8. Pulse 120. Respiration 28.

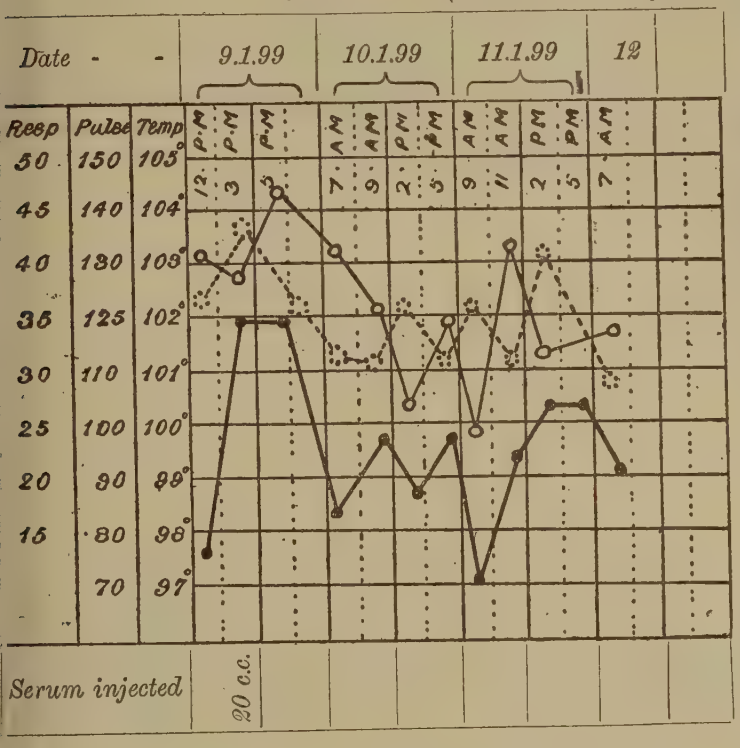
CASES OF PLAGUE

TREATED WITH

SERUM ANTI-PESTEUX FROM PASTEUR INSTITUTE. (HORSE No. 31.)

9.1.99.—One child, about three, admitted whose temperature fell to normal soon after admission, and who was, therefore, not inoculated.
One woman admitted who died almost directly after admission, and was not seen by me.

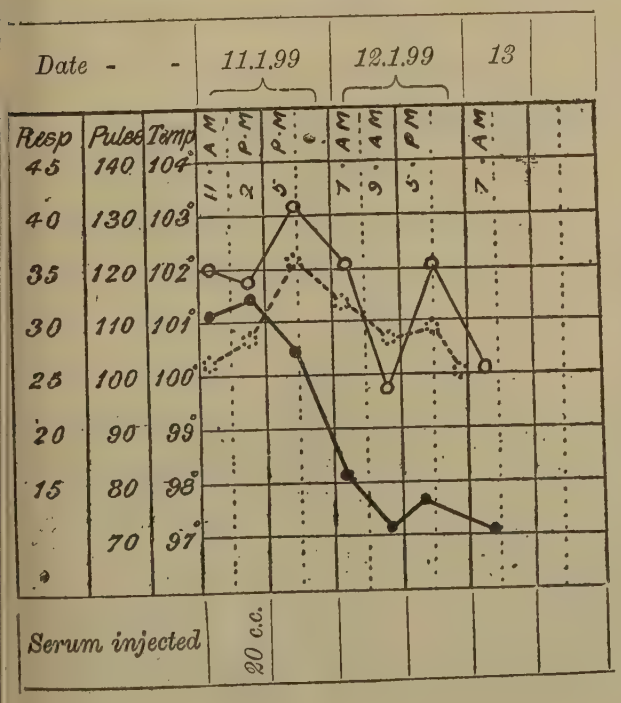
CASE No. I. A. (Admitted on 3rd day of the disease.)



Venkoba. Age 3. Male. Admitted **9.1.99.**—12.0 p.m. Fever for two days. Temp. 97·8°. Pulse 132. Respiration 36. 3.0 p.m.—General condition indifferent. Dull and apathetic. Bubo in right axilla. Temp. 102°. Pulse 128. Respiration 44. Heart and lungs clear (double cataract). 20 *c.c. serum inoculated.* 5.0 p.m.—Temp. 102°. Pulse 144. Respiration 36. **10.1.99.**—7.0 a.m.—Temp. 98·4°. Pulse 132. Respiration 32. 9.0 a.m.—Temp. 99·6°. Pulse 120. Respiration 30. Sleepy, but much better. 2.0 p.m.—Temp. 98·8°. Pulse 104. Respiration 36. Condition much improved. 5.0 p.m. Temp. 99·6°. Pulse 120. Respiration 30. **11.1.99.**—9.0 a.m.—Temp. 97.° Pulse 98. Respiration 36. 11.0 a.m.—Temp. 99·2°. Pulse 132. Respiration 30. 2.0 p.m.—Temp. 100·4°. Pulse 112. Respiration 40. Condition good. 5.0 p.m.—Temp. 100·4°. **12.1.99.**—7.0 a.m.—Temp. 99°. Pulse 116. Respiration 28. Bubo suppurated.

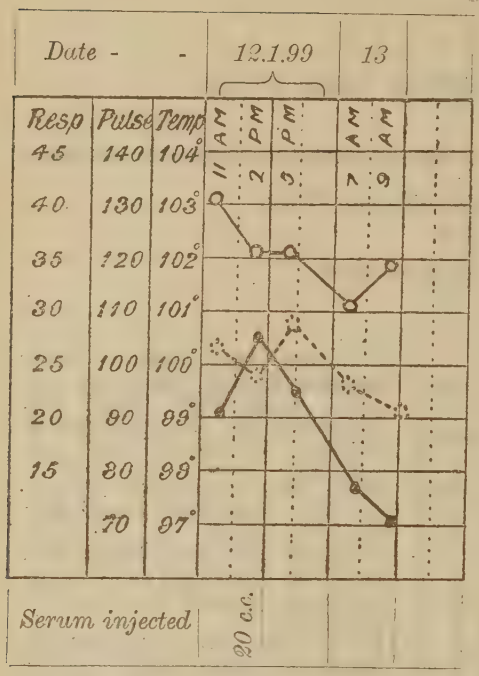
11.1.99.—Two cases admitted, but died before they were seen.

CASE No. II. A. (Admitted on 5th day of the disease.)



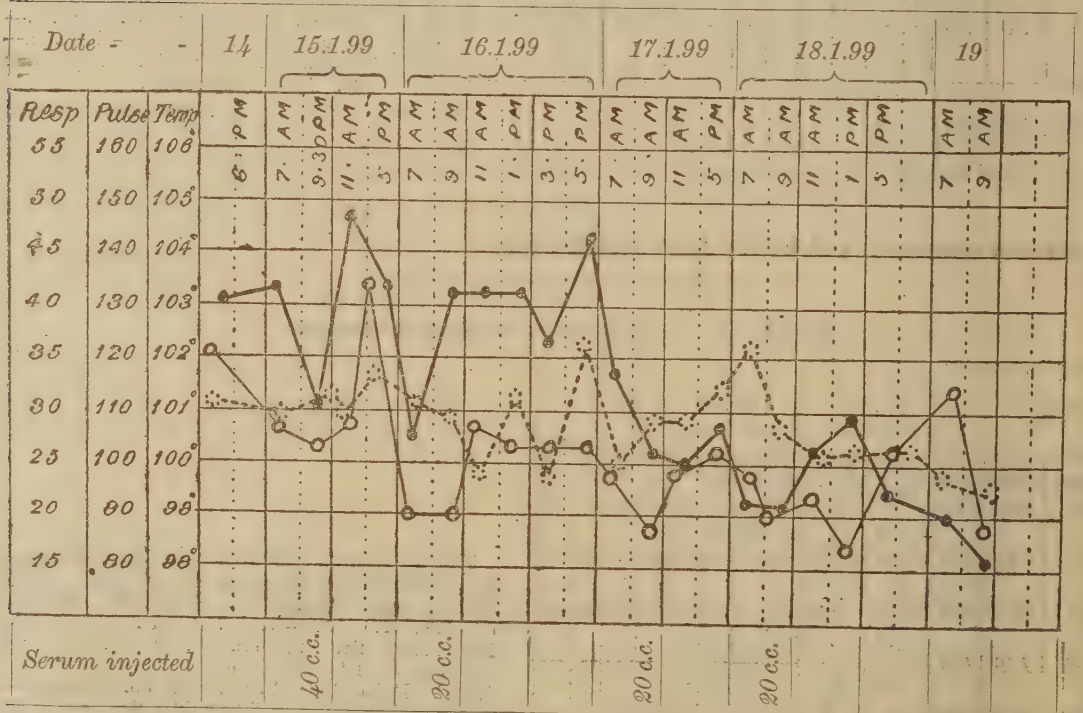
Thaiaro. Age 13. Female. Admitted **11.1.99.**—11.0 a.m.—Pain in the neck for six days. Fever for four days. Temp. 101°. Pulse 120. Respiration 26. 2.0 p.m.—Temp. 101·4°. Pulse 116. Respiration 28. 20 *c.c. serum.* Very small swelling on left side of neck. 5.0 p.m.—Temp. 100·4°. Pulse 132. Respiration 36. **12.1.99.**—7.0 a.m.—Temp. 98°. Pulse 120. Respiration 32. 9.0 a.m.—Temp. 97·2°. Pulse 96. Respiration 28. Practically well. 5.0 p.m.—Temp. 97·8°. Pulse 120. Respiration 30. **13.1.99.**—7.0 a.m.—Temp. 97°. Pulse 100. Respiration 26.

CASE No. III. A. (Admitted on 4th day of the disease.)



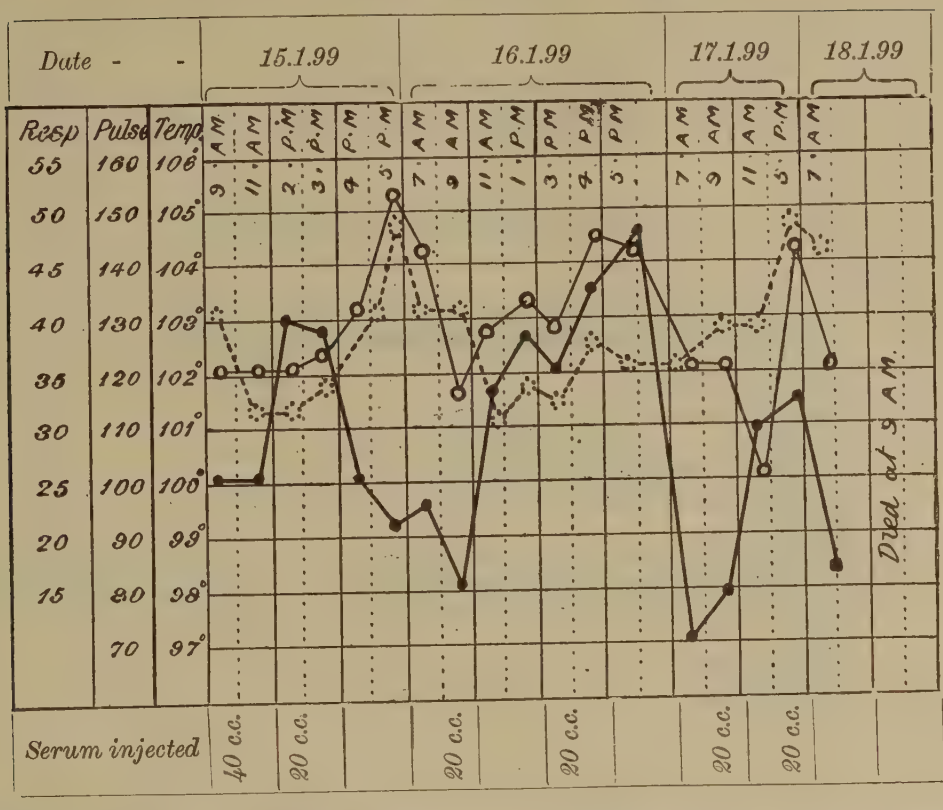
Mary. Age 2½. Female. Admitted **12.1.99.**—11 a.m. Bubo and fever three days. Temperature 99°. Pulse 130. Respiration 26. 2 p.m.—General condition good. Bubo in left groin. Heart and lungs normal. Temperature 100·6°. Pulse 120. Respiration 24. 20 *c.c. serum.* 5 p.m.—Temp. 99·6°. Pulse 120. Respiration 28. **13.1.99.**—7 a.m.—Temp. 97·8°. Pulse 110. Respiration 24. 9 a.m.—Temp. 97°. Pulse 120. Respiration 20. Practically well.

CASE No. IV. A. (Admitted on 4th day of the disease.)



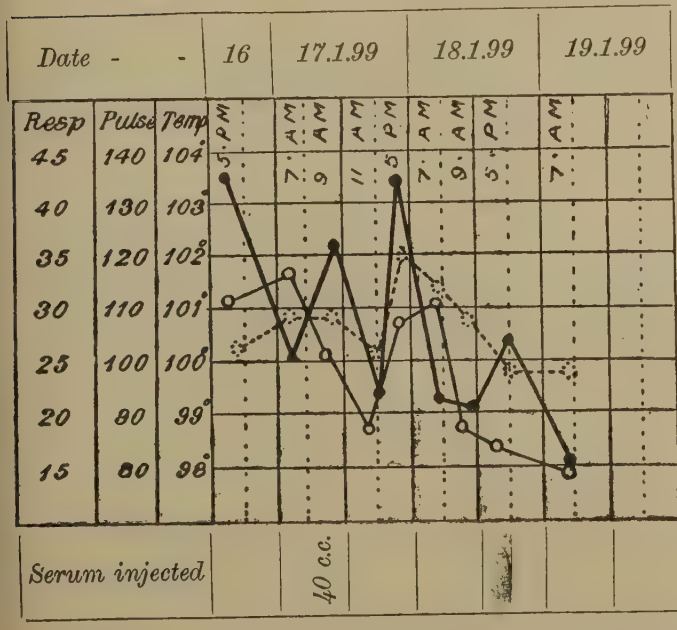
Pir. Khan. Age 35. Male. Admitted **14.1.99.**—6 p.m.—Bubo and fever for three days. Temperature 103°. Pulse 120. Respiration 30. **15.1.99.**—7 a.m.—Temp. 103·4°. Pulse 108. Respiration 28. 9.30 a.m.—Temp. 101°. Pulse 104. Respiration 32. General condition fair. Bubo in left groin. Heart and lungs natural. 40 *c.c. serum.* 11 a.m.—Temp. 104·8°. Pulse 108. Respiration 30. 5 p.m.—Temp. 103·4°. Pulse 136. Respiration 34. **16.1.99.**—7 a.m.—Temp. 100·4°. Pulse 90. Respiration 28. 9 a.m.—Temp. 103·2°. Pulse 90. Respiration 30. Pulse good. Sensible. 20 *c.c. serum.* 11 a.m.—Temp. 103·2°. Pulse 108. Respiration 24. 1 p.m.—Temp. 103·2°. Pulse 104. Respiration 32. Complains of pain in left epitrochlear region. 3 p.m.—Temp. 102·4°. Pulse 104. Respiration 24. 5 p.m.—Temp. 104·4°. Pulse 104. Respiration 36. **17.1.99.**—7 a.m.—Temp. 101·8°. Pulse 98. Respiration 24. 9 a.m.—Temp. 100·4°. Pulse 88. Respiration 28. 20 *c.c. serum.* Slightly delirious. 11 a.m.—Temp. 100. Pulse 100. Respiration 28. 5 p.m.—Temp. 100·8°. Pulse 104. Respiration 32. **18.1.99.**—7 a.m.—Temp. 99·4. Pulse 98. Respiration 36. 9 a.m.—Temp. 99·2°. Pulse 92. Respiration 28. Talkative; rather incoherent. 20 *c.c. serum.* 11 a.m.—Temp. 100·4°. Pulse 96. Respiration 26. 1 p.m.—Temp. 101°. Pulse 84. Respiration 26. 5 p.m.—Temp. 99·6°. Pulse 104. Respiration 26. **19.1.99.**—7 a.m.—Temp. 99°. Pulse 116. Respiration 24. 9. a.m.—Temp. 98·4°. Pulse 84. Respiration 22. Much better. Tongue cleaning. Bubo painful. Epitrochlear tenderness disappeared. Bubo in left groin looked as if would suppurate.

CASE No. V. A. (Admitted on 4th day of the disease.)



Muragasum. Age 21. Male. Admitted **15.1.99.**—9 a.m. Ill for three or four days. General condition very bad Delirious, very restless, constantly picking at the bed-clothes. Eyes very injected. Temperature 100°. Pulse 120. Respiration 40. Bubo on left side of neck. 40 *c.c. serum.* 11 a.m.—Temp. 100°. Pulse 120. Respiration 32. 2 p.m.—Temp. 103°. Pulse 120. Respiration 32. 20 *c.c. serum* intravenous. 3 p.m.—Temp. 102·8°. Pulse 124. Respiration 34. 4 p.m.—Temp. 100°. Pulse 132. Respiration 40. 5 p.m.—Temp. 99·4°. Pulse 156. Respiration 48. **16.1.99.**—7 a.m.—Temp. 99·8°. Pulse 144. Respiration 40. 9 a.m.—Temp. 98°. Pulse 108. Respiration 40. General condition unchanged, still the same delirium, never still, always talking. 20 *c.c. serum* sub-cute. 11 a.m.—Temp. 101·8°. Pulse 128. Respiration 30. 1 p.m.—Temp. 102·6°. Pulse 132. Respiration 34. 3 p.m.—Temp. 102°. Pulse 128. Respiration 32. 20 *c.c. serum* intravenous. 4 p.m.—Temp. 103·4°. Pulse 144. Respiration 38. 5 p.m.—Temp. 104·4°. Pulse 144 Respiration 36. **17.1.99.**—7 a.m.—Temp. 97°. Pulse 120. Respiration 36. 9 a.m.—Temp. 98°. Pulse 120. Respiration 40. General condition, no better. 20 *c.c. serum.* 11 a.m.—Temp. 101°. Pulse 100. Respiration 40. 2 p.m.—Quieter evidently from exhaustion. Muttering. 20 *c.c.* sub-cute. Cultivation from blood made. No plague bacilli. 5 p.m.—Temp. 101·4°. Pulse 144. Respiration 48. **18.1.99.**—7 a.m.—Temp. 98·4°. Pulse 120. Respiration 46.

CASE No. VI. A. (Admitted on 5th day of the disease.)



Mooniappab. Age 50. Male. Admitted **16.1.99.**—5 p.m. Ill four days. Bubo four days. 5 p.m.—Temperature 103·6°. Pulse 110. Respiration 26. **17.1.99.**—7 a.m.—Temp. 100°. Pulse 118. Respiration 28. 9 a.m.—Temp. 102·2°. Pulse 100. Respiration 28. General condition good. Heart and lungs normal. Bubo in left groin. 40 *c.c. serum.* 11 a.m.—Temp. 99·4°. Pulse 88. Respiration 24. 5 p.m.—Temp. 103·4°. Pulse 108. Respiration 36. **18.1.99.**—7 a.m.—Temp. 99·4°. Pulse 110. Respiration 30. 9 a.m.—Temp. 99°. Pulse 88. Respiration 28. Much better. 5 p.m.—Temp. 100·4°. Pulse 84. Respiration 24. **19.1.99.**—7 a.m.—Temp. 98°. Pulse 80. Respiration 24.

ABSTRACT OF STATISTICS AT BANGALORE.

Cases admitted into South Camp Hospital before December 25th, 686.
Deaths, 403.
Percentage of deaths, 58·7.

Total cases admitted from 25.12.98 to 12.1.99, 73.
Deaths, 35.
Percentage of deaths, 47·9.

Total bubonic cases during same period, 39.
Deaths, 20.
Percentage, 51·3.

Total non-bubonic cases during same period, 34.
Deaths, 15.
Percentage of deaths, 44·1.

Total cases treated with Roux serum from 25.12.98 to 16.1.99, 49.
Deaths, 31.
Percentage, 63·26.

Total cases admitted into North Camp from September 15th to November 19th, 365.
Deaths, 275.
Percentage of deaths, 75·13.

Total cases from December 25th to January 12th, 54 cases.
Total deaths, 29.
Percentage of deaths, 53·7.

Total bubonic cases, 14.
Deaths among bubonic cases, 10.
Percentage, 71·42.

APPENDIX No. LXXX.

NOTES

OF

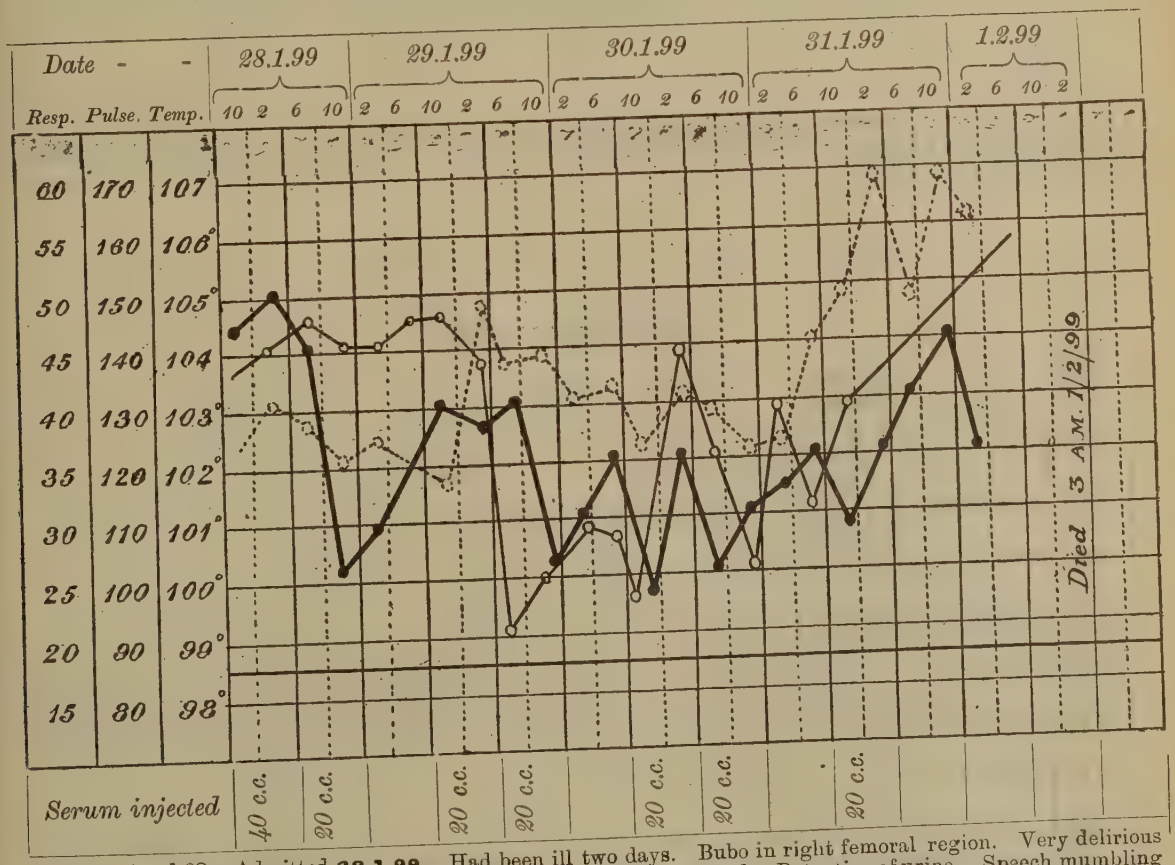
CASES TREATED WITH ROUX' SERUM AT MODI KHANA HOSPITAL, BOMBAY, WITH AN EQUAL NUMBER OF CONTROLS,

BY

LIEUT. S. R. DOUGLAS, I.M.S.
On Special Duty with the Indian Plague Commission.

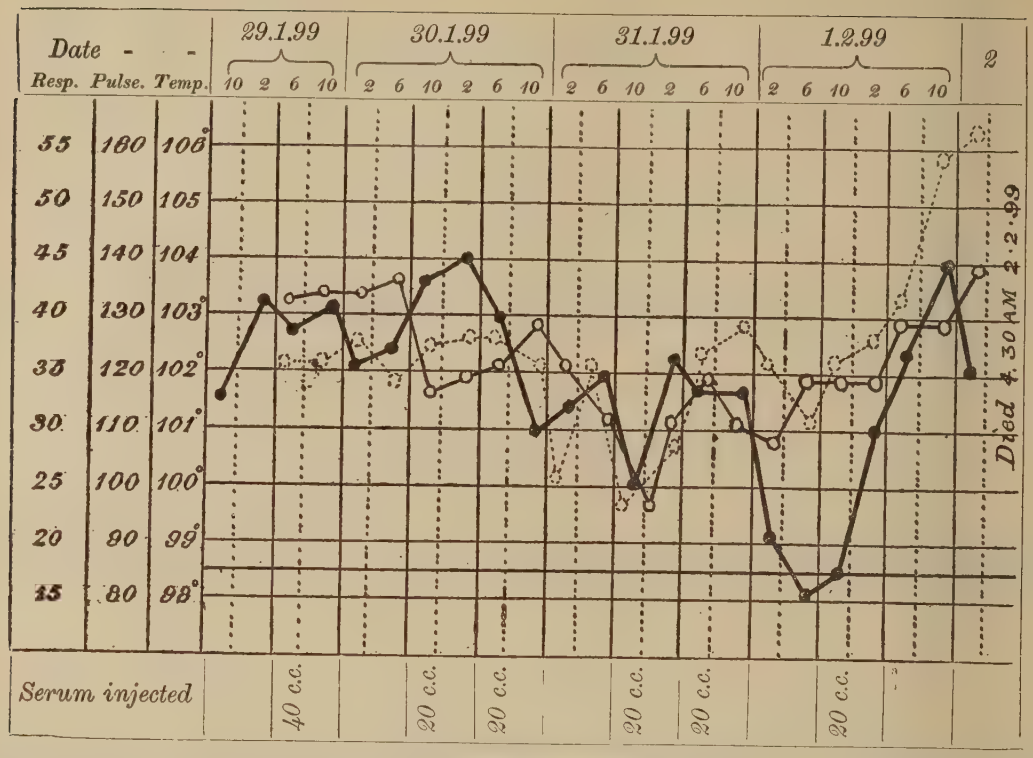
NOTE.—The numbers in brackets are the numbers of the cases in the Register at the Modi Khana Hospital. Observations in cases treated with Roux' serum are made every 4 hours, at 2, 6, and 10 a.m., and at 2, 6, and 10 p.m. The thick black line indicates the temperature, the thin black line the pulse, and the dotted line the respiration.

CASE No. I. (No. 1654.)



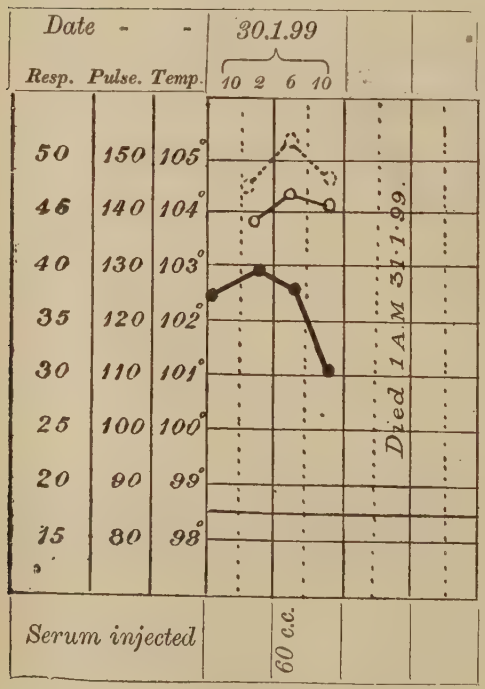
Male. Aged 28. Admitted **28.1.99.** Had been ill two days. Bubo in right femoral region. Very delirious Much bruised about the face. Heart and lungs, no abnormalities found. Retention of urine. Speech mumbling indistinct. **29.1.99.**—Slightly better apparently, still delirious. Bubo has more infiltration round it. **30.1.99** —Has developed a corneal ulcer. **31.1.99.**—Quiet, seemingly exhausted. Bubo softer and has extended upwards.

CASE No. II. (No. 1669.)



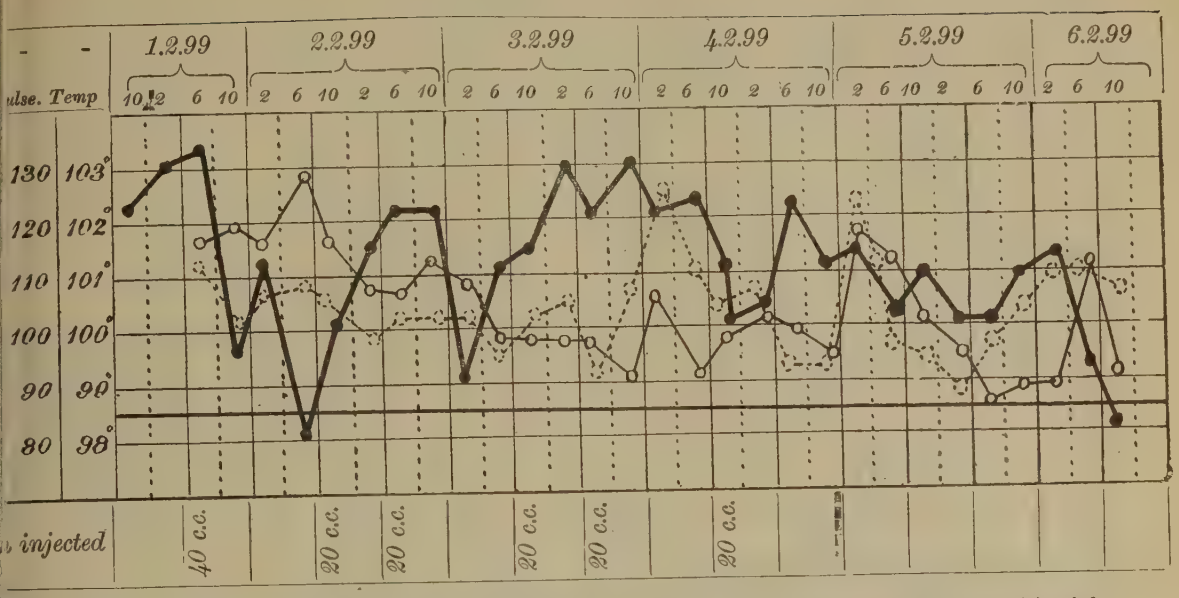
Male. Aged 35. Ill three days before. Bubo in left groin. Patient is conscious. Heart and lungs, nothing abnormal found. **30.1.99.**—Rather delirious. Speech very indistinct. **31.1.99.**—Slept well, not so delirious. **1.2.99.**—Worse, very delirious.

CASE No. III. (No. 1680.)



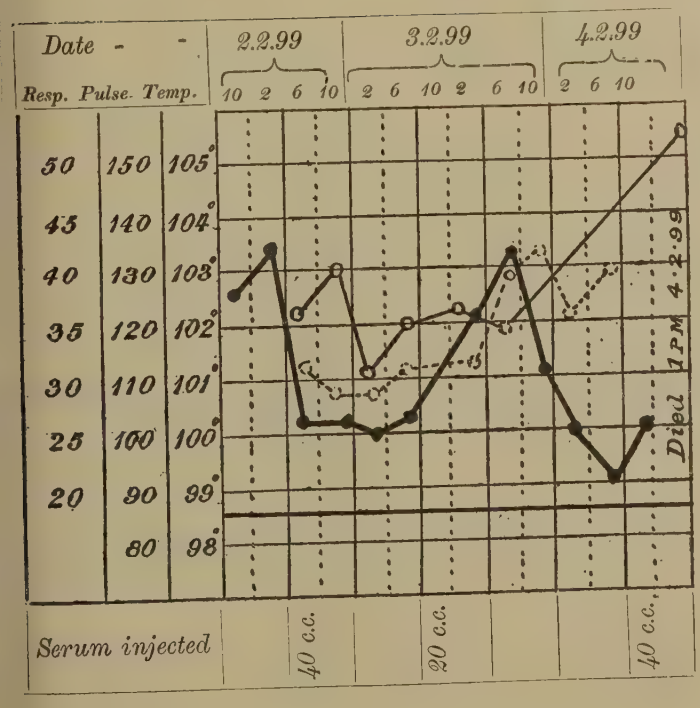
Male. Age 28. Admitted **30.1.99.** Ill for two days. Bubo in left groin. Unconscious. Quiet, but rather restless. Blood drawn off. (Culture made; many colonies of bacilli.)

CASE No. IV. (No. 1700.)



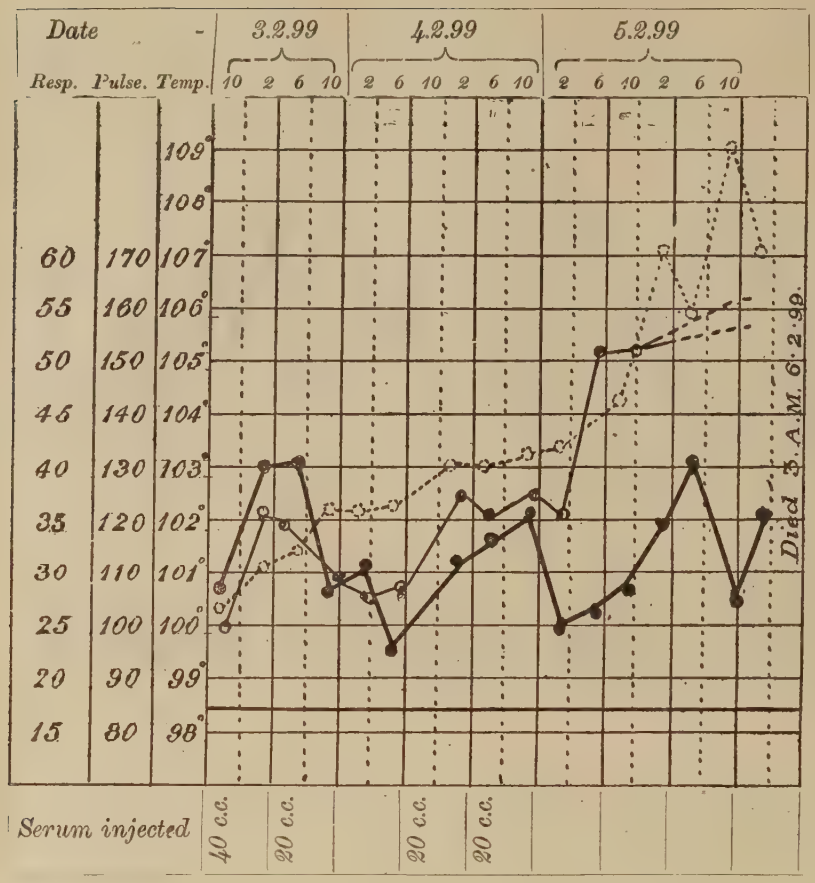
Male. Age 30. Admitted **1.2.99.** Ill for two days. Bubo in left groin. Has cough; râles in rhonchi in right ng. **2.2.99.**—Slept well. Pulse good. **3.2.99.**—Gland less painful. Pulse fair. **4.2.99.**—Eyes rather ected. Pulse good. **5.2.99.**—No serum given. Patient improving. Very weak. **6.2.99.**—Bubo incised. pus, but some necrosed gland removed. **17.3.99.**—Patient discharged.

CASE No. V. (No. 1712.)



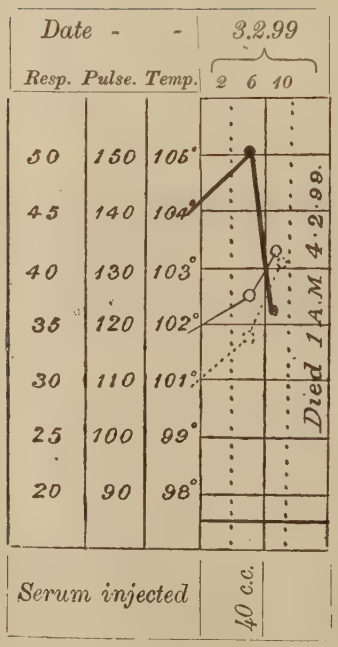
Male. Age 40. Admitted **2.2.99.** Ill for two days. Bubo in left inguinal region. Speech indistinct. Prolonged expiration and rhonchi over both lungs. **3.2.99.**—No sleep. Gurgling respiration. Eyes injected. **4.2.99.**—Limbs cold. Pulse running.

CASE No. VI. (No. 1722.)



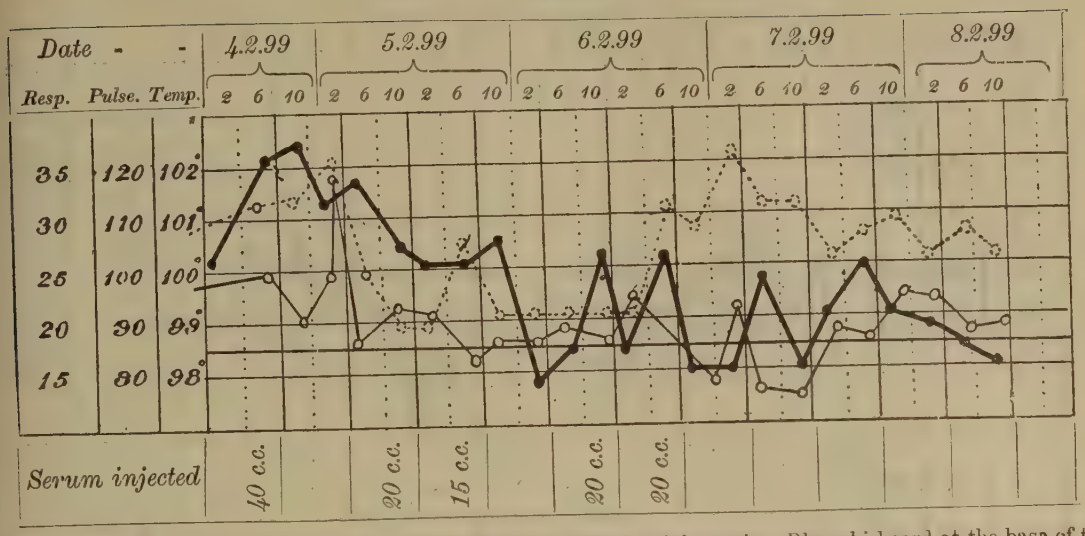
Male. Age 30. Admitted **3.2.99.** Ill for three days. Bubo in right submaxillary region. Very large. Eyes injected. Has difficulty in swallowing. **4.2.99.**—Muttering delirium. No sleep. Swelling round bubo has increased. **5.2.99.** — Respiration very rapid. Pulse running.

CASE No. VII. (No. 1730.)



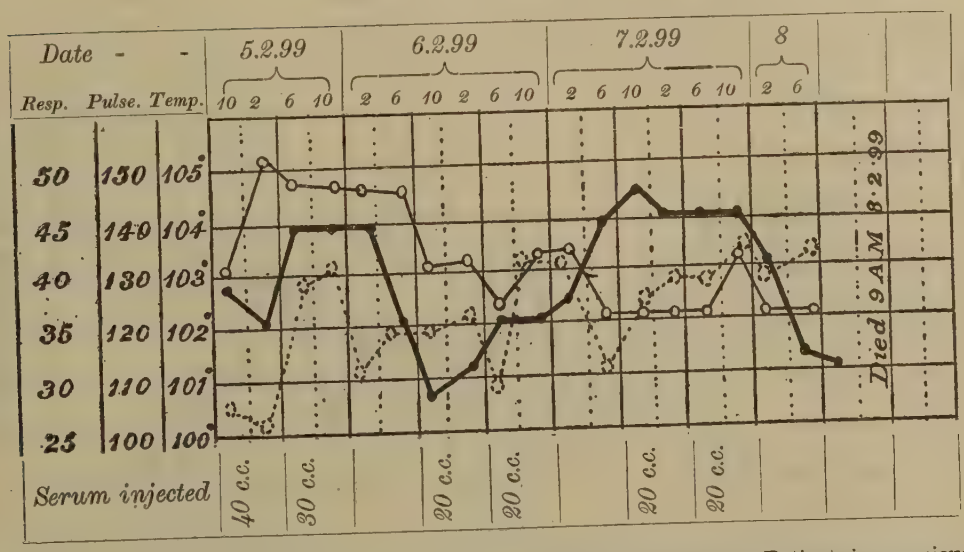
Male. Age 30. Admitted **3.2.99.** Ill for four days. Bubo in left femoral region. Lungs not affected. Speech very indistinct. Limbs cold.

CASE No. VIII. (No. 1743.)



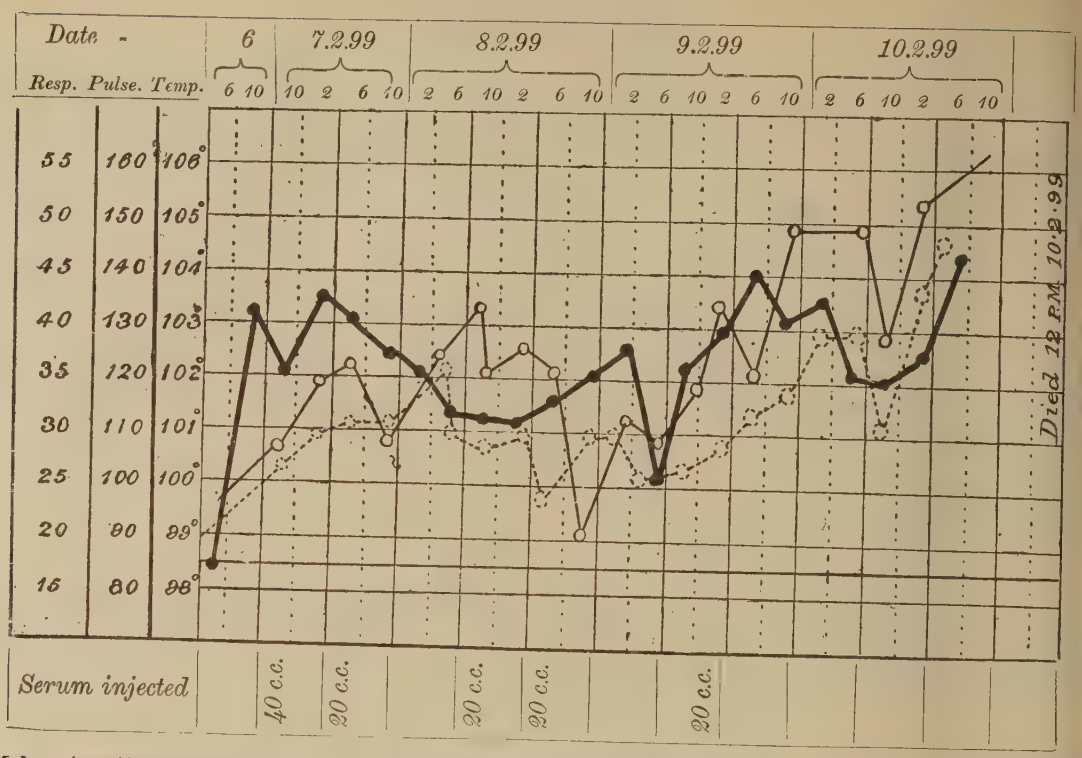
Male. Aged 25. Admitted **4.2.99.** Ill for four days. Bubo in right groin. Rhonchi heard at the base of the right lung. Speech indistinct. **5.2.99.**—Condition unchanged. Slept well. 6.2.99.—Gland still hard, slight improvement. **7.2.99.**—Serum discontinued. improvement continues. 10.2.99.—Bubo incised, some pus and broken down gland escaping. **15.3.99.**—Discharged.

CASE No. IX. (No. 1747.)



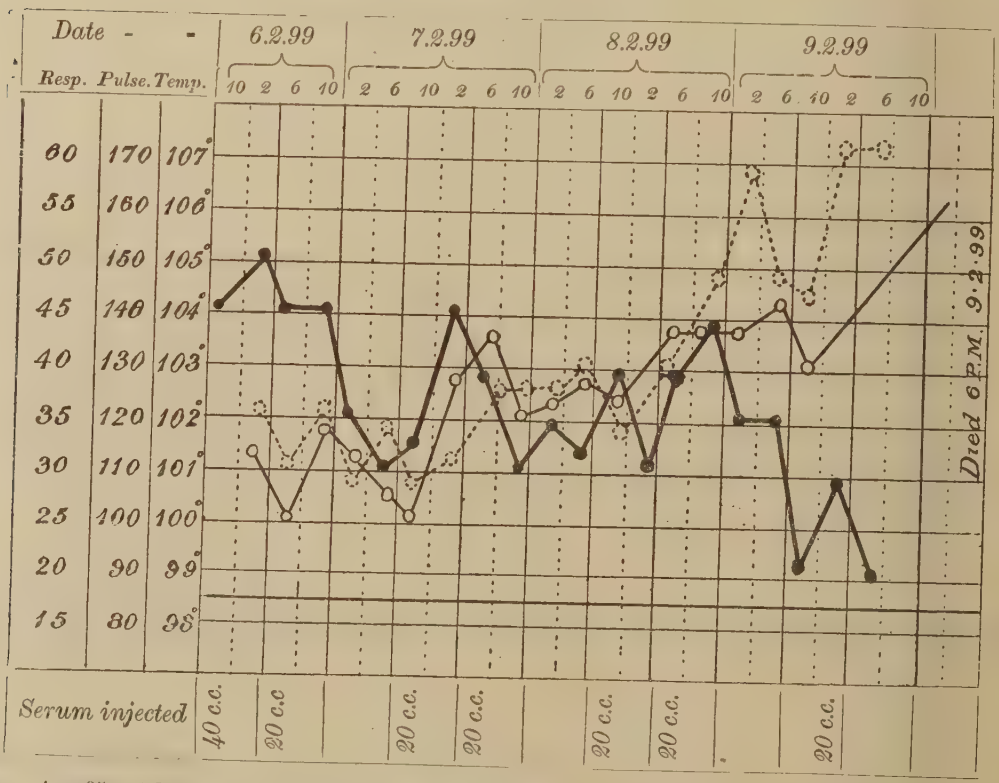
Male. Aged 24. Admitted **5.2.99.** Ill for four days. Bubo in right axilla. Patient is conscious. Heart and lungs clear. **7.2.99.**—Quiet all night. Eyes very injected. **8.2.99**—Respiration shallow. Extremities cold.

CASE No. X. (No. 1763.)



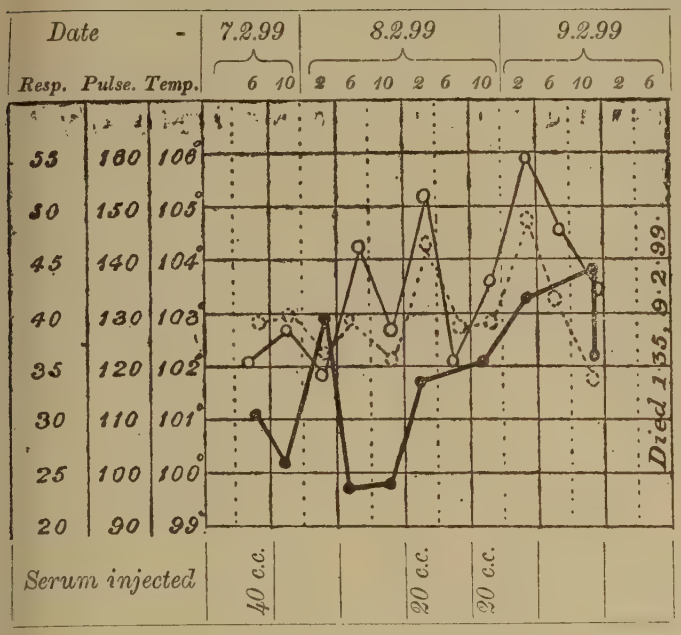
Male. Age 40. Admitted **6.2.99.** Ill for three days. Bubo in left axilla. **7.2.99.**—Râles and rhonchi heard over both lungs. Is very delirious. **8.2.99.**—Very delirious. Pulse very bad. **9.2.99.**—Condition unchanged. **10.2.99.**—Speech very indistinct. Pulse running. Extremities cold.

CASE No. XI. (No. 1766.)



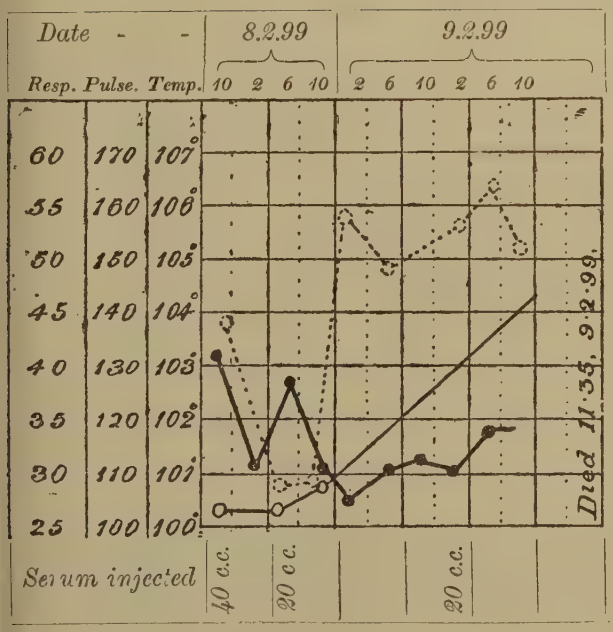
Male. Age 25. Admitted **6.2.99.** Ill for two days. Bubo in right femoral region. Conscious. Heart and lungs unaffected. **7.2.99.**—Slept well. Has retention of urine. **8.2.99.**—Has another gland in left groin, retention of urine continues. **9.2.99.**—Violently delirious. Respiration very rapid. Pulse running.

CASE No. XII. (No. 1783.)



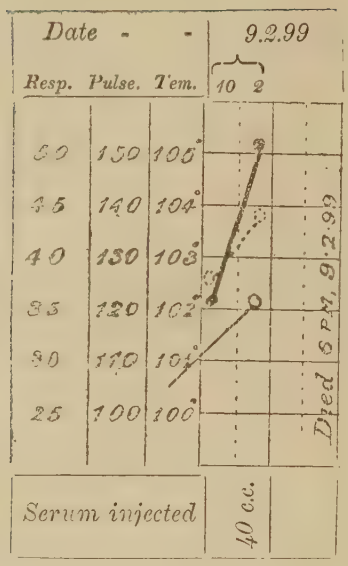
Male. Age 24. Admitted **7.2.99.** Ill for two days. Bubo in left axilla. Conscious. Sibilant rhonchi over both lungs. **8.2.99.**—Quiet, but general condition worse. Pulse rapid. **9.2.99.**—Very delirious.

CASE No. XIII. (No. 1788.)



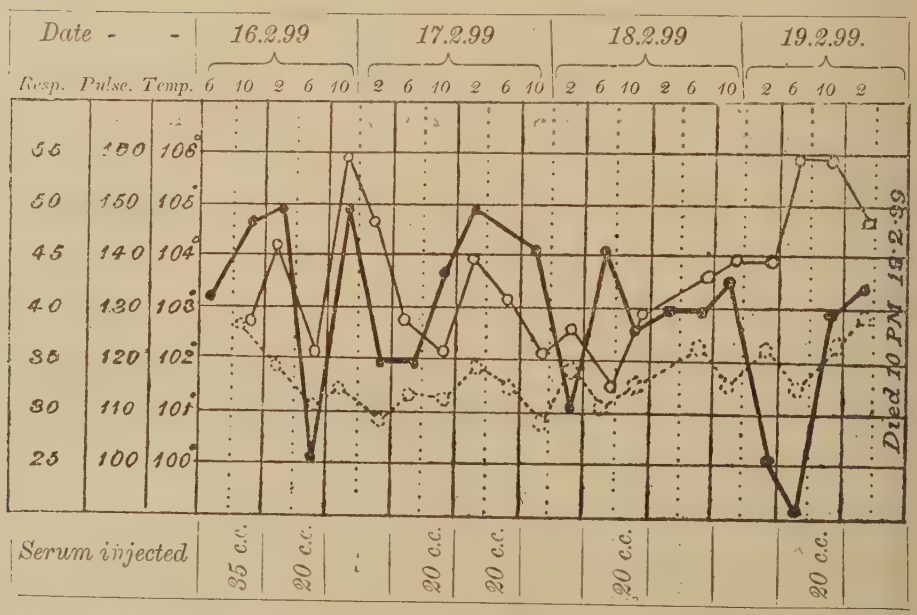
Male. Age 30. Admitted **8.2.99.** Ill for two days. Bubo in right groin. Lungs not affected. **9.2.99.**—Breathing has become very rapid. Pulse running.

CASE No. XIV. (No. 1805.)



Male. Aged 25. Admitted **9.2.99.** Ill for three days. Bubo in right groin. Bronchial breathing heard over the whole of the left lung.

CASE No. XV. (No. 1864.)

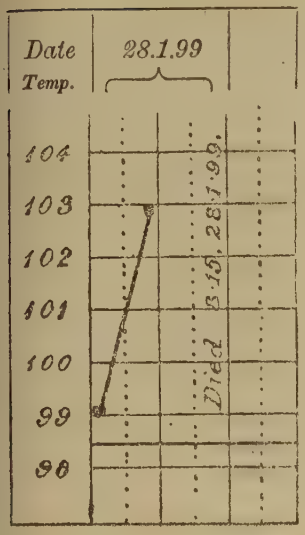


Male. Aged 25. Admitted **15.299.** Ill for two days. Bubo in right femoral region. Patient conscious. Lungs, prolonged expiration at both bases, with rhonchi at the end of expiration. **16.2.99.**—Rather restless. Pulse weak. **17.2.99.**—Condition unchanged, rather worse if anything. **18.2.99.**—Becoming weaker, pulse rapid, very soft. **19.2.99.**—Delirious during night. Now exhausted.

CONTROLS.

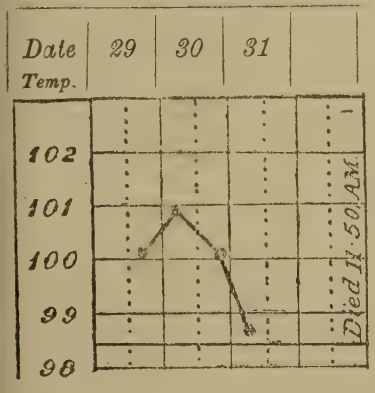
NOTE.—The charts of control cases show the temperature only, observed in the morning and evening each day.

CASE No. I. c. (No. 1652.)



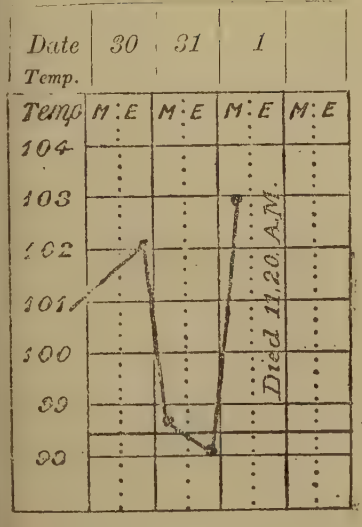
Male. Age 20. Admitted **28.1.99.** Ill two days. Bubo in right femoral region.

CASE No. II. c. (No. 1673.)



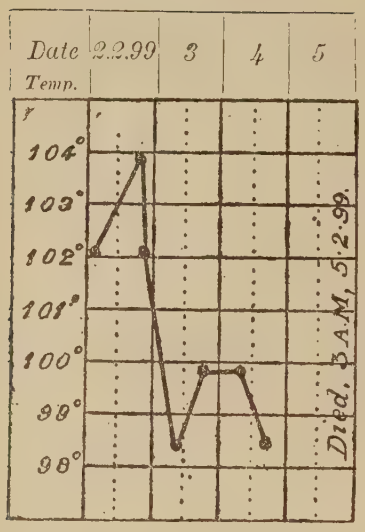
Male. Age 22. Admitted **29.1.99.** Ill three days. Bubo in right axilla.

CASE No. III. c. (No. 1685.)



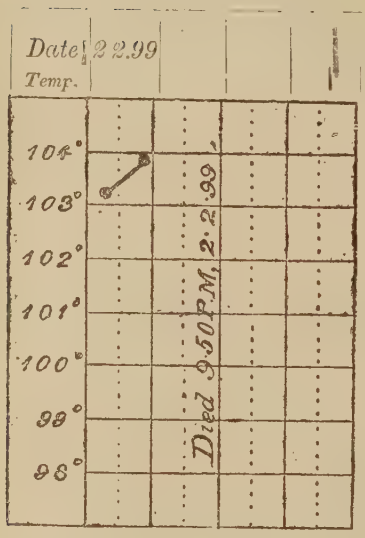
Male. Age 30. Admitted **30.1.99.** Ill two days. Bubo in left popliteal region.

CASE No. IV. c. (No. 1707)



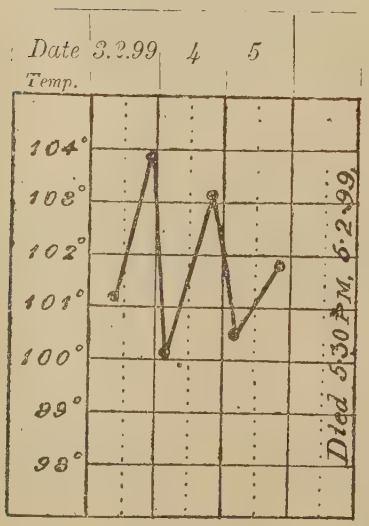
Male. Aged 40. Admission **1.2.99.** Ill six days? Bubo in right groin.

CASE No. V. c. (No. 1714.)



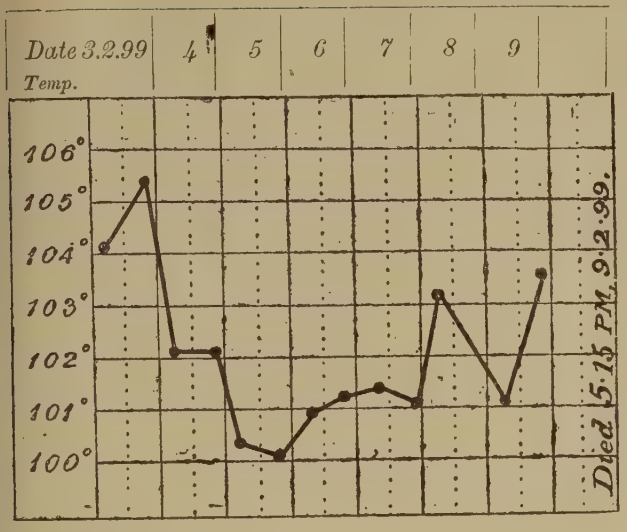
Male. Aged 35. Admitted **2.2.99.** Ill three days. Bubo right femoral region.

CASE No. VI. c. (No. 1725.)



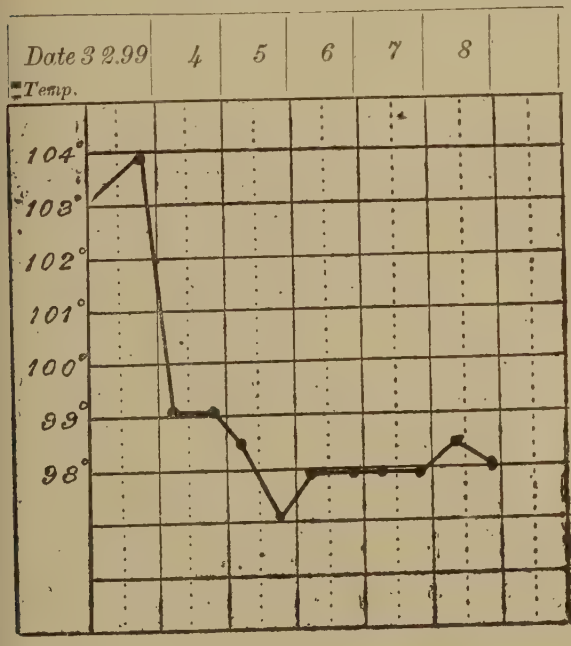
Male. Aged 50. Admitted **3.2.99.** Ill three days. Bubo in right femoral region.

CASE No. VII. c. (No. 1729.)



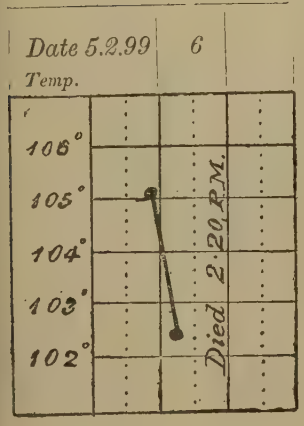
Male. Age 20. Admitted **3 2.99.** Ill for four days. Bubo left groin.

CASE No. VIII. c. (No. 1731.)



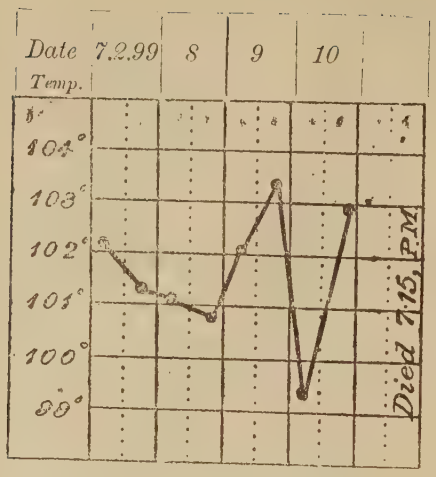
Male. Age 19. Admitted **3.2 99.** Ill for seven days. Bubo in right groin. Discharged cured **13.2.99.** Bubo did not suppurate.

CASE No. IX. c. (No. 1753.)



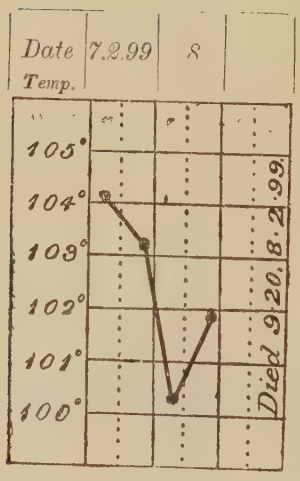
Male. Age 35. Admitted **5.2.99.** Ill for three days. Bubo in right groin.

CASE No. X. c. (No. 1774.)



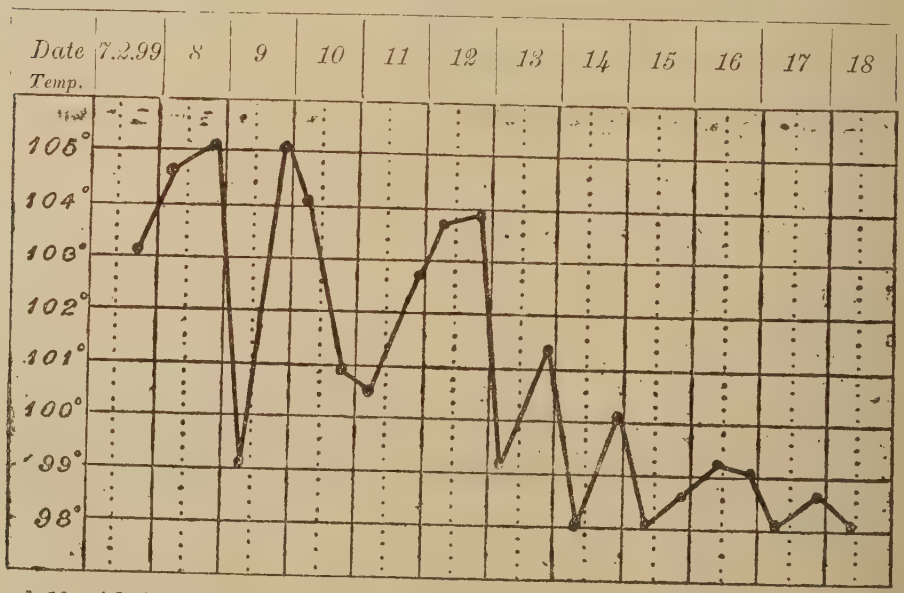
Male. Aged 18. Admitted **7.2.99.** Ill for two days. Bubo in right groin.

CASE No. XI. c. (No. 1777.)



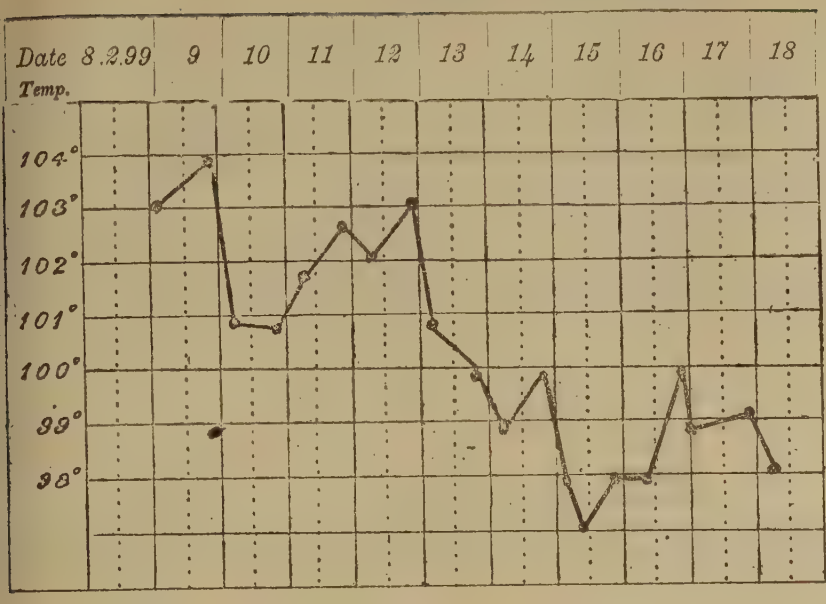
Male. Aged 25. Admitted **7.2.99.** Ill for two days. Bubo in right femoral region.

CASE No. XII. c. (No. 1782.)



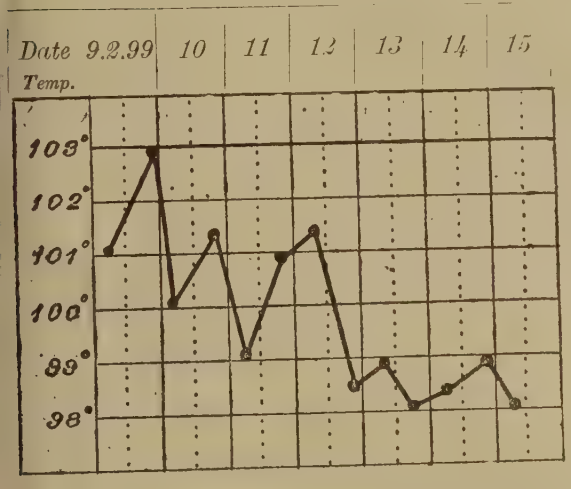
Male. Aged 10. Admitted **7.2.99.** Ill for two days. Bubo left side of neck. Bubo opened **4.3.99.** Developed many (5 or 6) pyæmic abscesses, from which were grown bacilli resembling coli. Discharged well, **23.3.99.**

CASE No. XIII. c. (No. 1901.)



Male. Age 25. Admitted **8.2.99.** Ill three days. Bubo in right femoral region. Bubo opened **16.2.99.** Discharged **23.3.99.**

CASE No. XIV. c. (No. 1807.)



Male. Age 50. Admitted **9.2.99.** Ill for three days. Bubo in left axilla. Bubo opened **24.2.99.** Discharged **17.3.99.**

CASE No. XV. c. (No. ——.)

Notes lost.

Patient died.

Results :—

15 cases treated with serum.
2 recoveries.

15 cases treated without serum.
4 recoveries.

Up to February 7th, 1899, horse 31 serum was used, after that date Horse No. 21.

RECORD OF
PLAGUE PATIENTS AT THE MODI KHANA HOSPITAL, BOMBAY,
TREATED WITH M. ROUX' SERUM,
TOGETHER WITH RECORD OF CONTROL CASES,

by

H. J. WALTON, M.B., F.R.C.S., LIEUT. I.M.S.,
On Special Duty with the Indian Plague Commission.

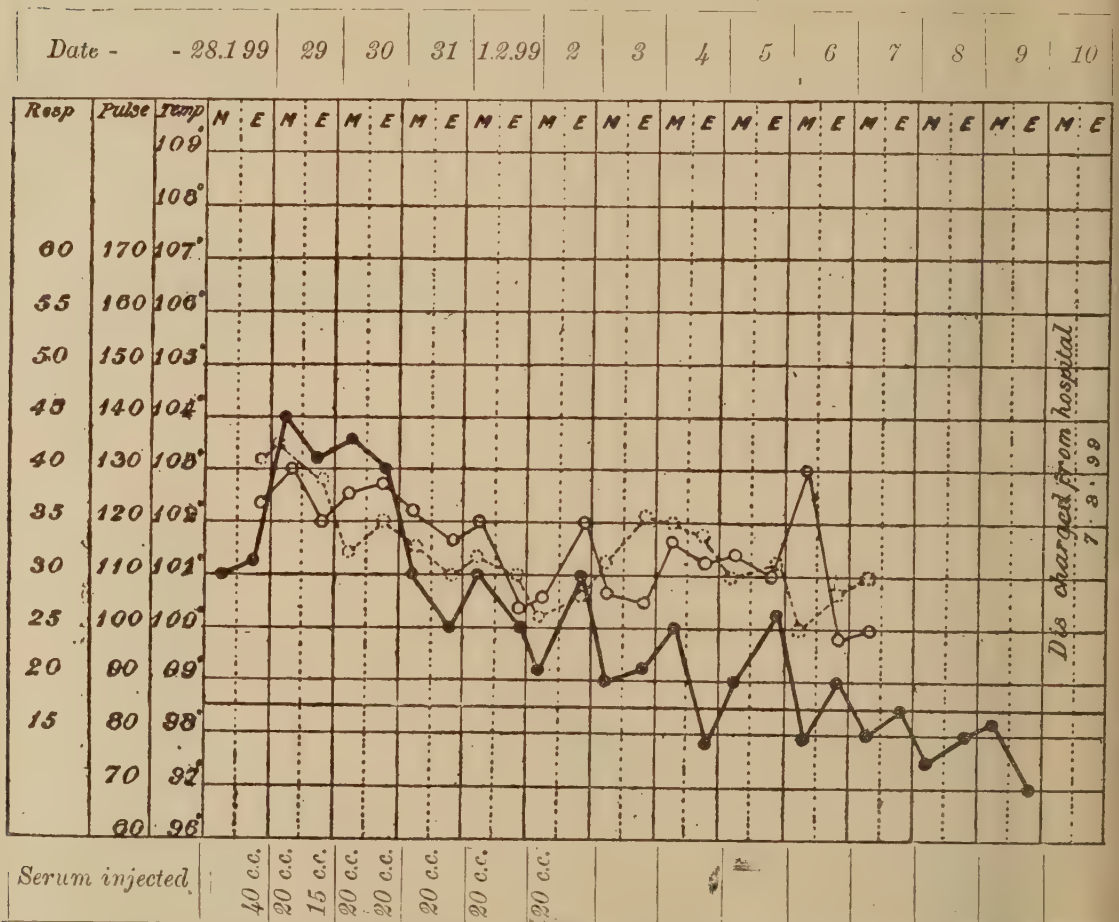
I.

CASES TREATED WITH ROUX' SERUM.

Total number	13
Died	10
Recovered	3
Percentage mortality	76·9

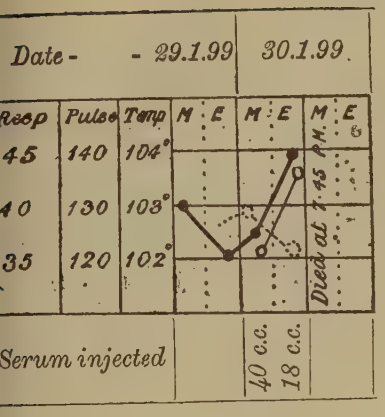
NOTE.—The numbers in brackets at the beginning of each case are those of the Register at the Modi Khana Hospital. The temperature is shown by a thick black line, the pulse by a thin black line, and the respiration by a dotted line.

CASE No. I. (No. 1656 (Control No. 1664).)



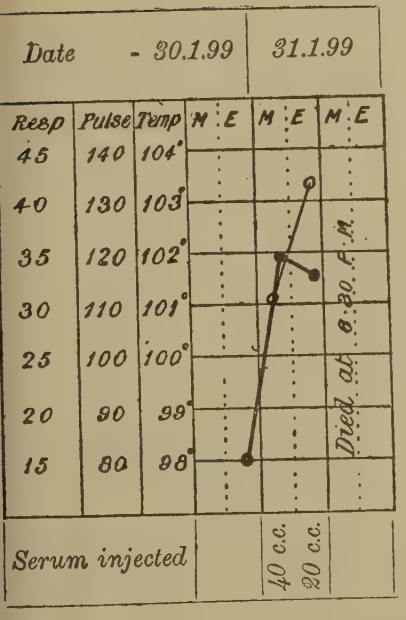
Dhondoo Trimak. Male. Age 23. Brahman. **28.1.99.**—Admitted to hospital with fever and gland in the left axilla. Well developed man. Has been ill for six days. Small tender bubo in left axilla. Is delirious and throwing himself about. Has retention of urine, necessitating catheterisation. 4.30 p.m.—Pulse 128; very poor volume. Temperature 102°. Respiration 32. Tongue thickly coated. Spleen not felt. Liver dulness normal. Heart and lungs normal. A blood film was examined microscopically and blood planted on agar; both gave negative results. 40 *c.c. of serum* in flanks. **29.1.99.**—10 a.m.—Was very delirious all night; quiet and conscious this morning. Pulse 130; better volume. Respiration 42. Temperature 104°. 20 *c.c. of serum*, No. 31. 6 p.m.—Quite quiet and sensible. Heart and lungs again examined and found normal. 15 *c.c. of serum*. **30.199.**—10 a.m.—Quite sensible. Bubo larger. Pulse, fair volume. 20 *c.c. of serum*. 6 p.m.—Condition unaltered. 20 *c.c. of serum*. **31.1.99.**—Quiet and sensible. Volume of pulse steadily improving. Says he feels much better. Tongue cleaning. 20 *c.c. of serum*. **1.2.99.**—Doing very well; talks well. Complains of pain about the bubo. 20 *c.c. of serum*. **2.2.99.**—Slept badly. Retention of urine continues, but passed a small quantity after application of turpentine stupes. Is very weak. 20 *c.c. of serum*. **3.2.99.**—Doing well. Passes urine naturally. Patient gradually improved, and was discharged from hospital on March 7th, 1899.

CASE No. II. (No. 1670 (Control No. 1667).)



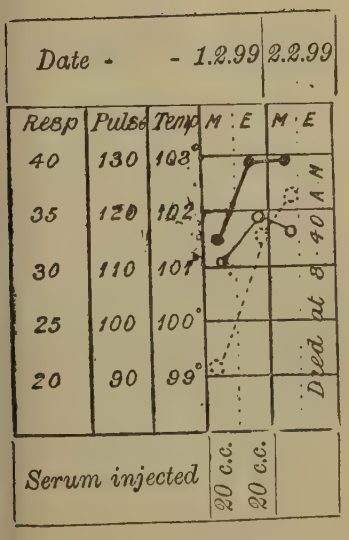
Pandu Mahadu. Male. Age 28. Hindu. Mill hand. **30.1.99.**—10 a.m.—Ill for three days. Small, painful gland in right axilla. Tongue furred at sides, bare in centre. Heart and lungs normal. Quite conscious and talks rationally. Pulse very weak. 40 *c.c. serum.* No. 31. 6 p.m.—Much weaker. 18 *c.c. of serum.*

CASE No. III. (No. 1686 (Control No. 1690).)



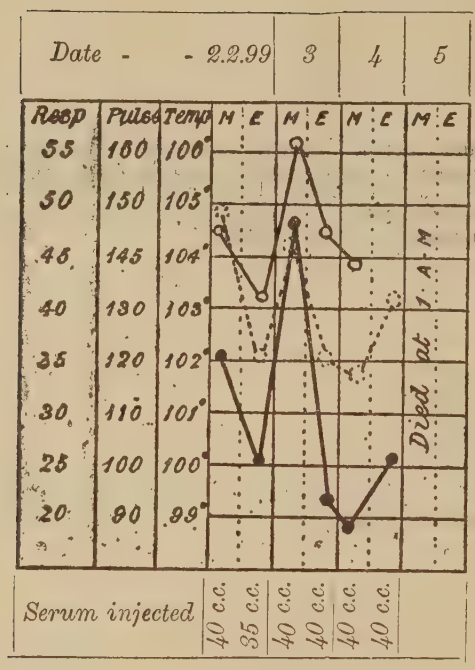
Yanu Paya. Male. Age 40. Hindu. Hamal. **30.1.99.**—Ill for two days. Fever and gland in right femoral region. Is quite conscious and answers questions. Tongue coated. Pulse very compressible and of poor volume. **31.1.99.**—10 a.m.—Small bubo, not very tender. Much œdema around. Heart normal. Lung, râles and rhonchi at both bases behind. Spleen not felt. Liver dulness normal. Conjuctivæ injected. 40 *c.c. of serum,* No. 31. 5 p.m.—Pulse very weak. Patient is semi-conscious. Answers when roused. Alternately drowsy and restless, throwing himself about and picking at the bed clothes. 20 *c.c. of serum* in subcutaneous vein.

CASE No. IV. (No. 1697 (Control No. 1675).)



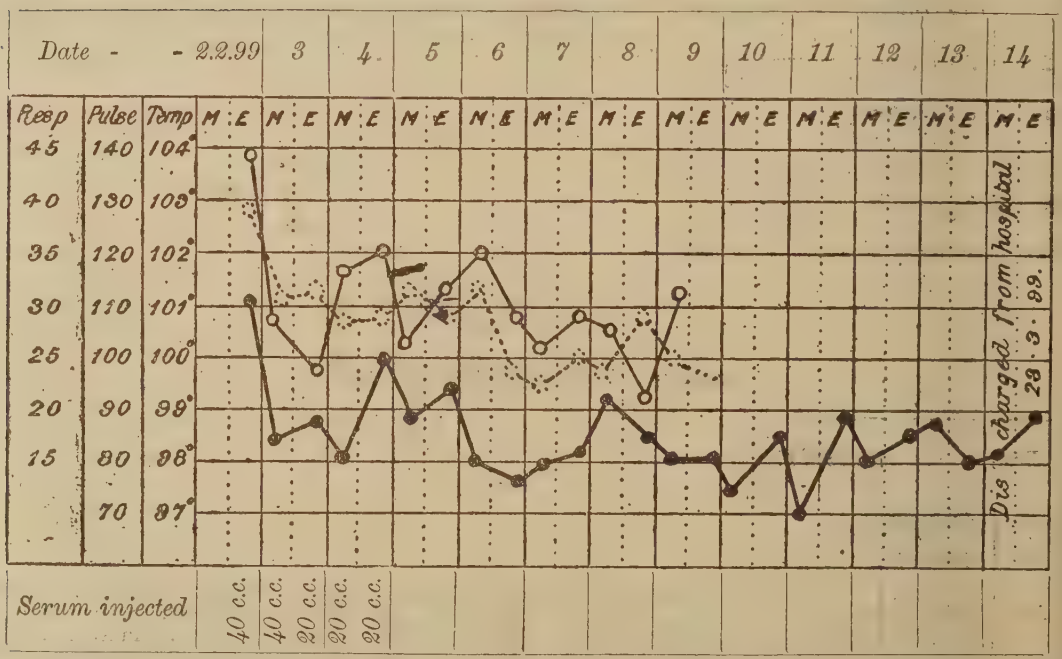
Tatwardas Ramnath. Male. Age 45. Hindu. Mendicant. **1.2.99.**—10 a.m.—Ill for three days. Moderate bubo in left groin. Hard and painful. Eyes injected. Tongue furred all over. Pulse fairly good volume. Heart normal. Lungs. Moist sounds at both bases behind. A few scattered rhonchi, both sides front. Spleen and liver normal. 20 *c.c. of serum,* No. 31. 6 p.m.—General condition fairly good. 20 *c.c. of serum.* **2.2.99.**—Slept fairly well. Pulse became very bad at 6 a.m.

CASE No. V. (No. 1708 (Control No. 1709).)



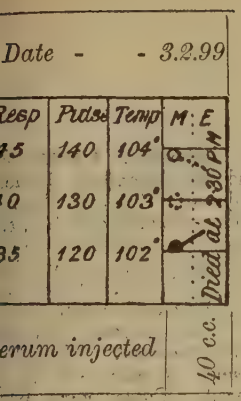
Ghulam Imamdin. Male. Age 18 (?). Muhammadan. Labourer **2.2.99.**—10 a.m.—Admitted with fever and gland in right axil Extremities cold. Shivering. Semi-conscious, but very drows Tongue coated, eyes injected. Too ill to admit of detail examination. 40 *c.c. of serum*, No. 31. 6 p.m.—Pulse sho marked dicrotism. Very drowsy. Can scarcely be roused, a then does not understand what is said to him. 35 *c.c. of seru* **3.2.99.**—10 a.m.—Condition very bad. Noisy delirium, a twitching in limbs and facial muscles. 40 *c.c. of serum.* 6 p.m —Condition unchanged. 40 *c.c. of serum.* **4.2.99.**—10 a.m. Pulse extremely weak. Lips covered with sordes. Extremiti cold. 40 *c.c. of serum.* 5.30 p.m.—Patient appears to moribund. Profuse sweat on forehead. Picks feebly at the be clothes. 40 *c.c. of serum.*

CASE No. VI. (No. 1716 (Control No. 1699).)



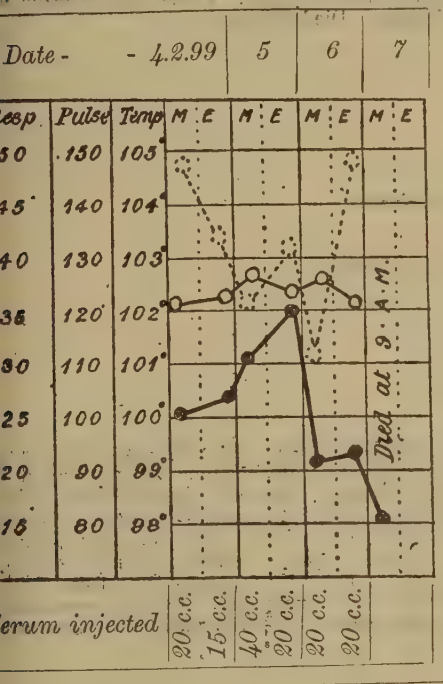
Daji Bobaji. Male. Age 30. Hindu. Labourer. **2.2.99.**—Said to have been ill for eight days. Quite conscious. Eyes injected. Speech slightly affected. Bubo with ulcerated surface in right groin. Râles, rhonchi and bronchial breathing scattered over both lungs. Pulse soft and compressible. 40 *c.c. of serum*, No. 31. **3.2.99.**—10 a.m.—Had a very bad night. Is quite conscious, but very weak this morning. Occasional paroxysms of coughing. Lungs full of râles. Was collapsed for a short time early this morning. 40 *c.c. of serum.* 6 p.m. —General condition bad. Pulse very poor volume. 20 *c.c. of serum.* **4.2.99.**—10 a.m.—Very weak. Cough rather better. Says he feels better than yesterday. 20 *c.c. of serum.* 5.30 p.m.—20 *c.c. of serum.* **5.2.99.**— Distinctly better. Pulse still very weak. **8.2.99.**—Doing well.

CASE No. VII. (No. 1720 (Control No. 1721).)



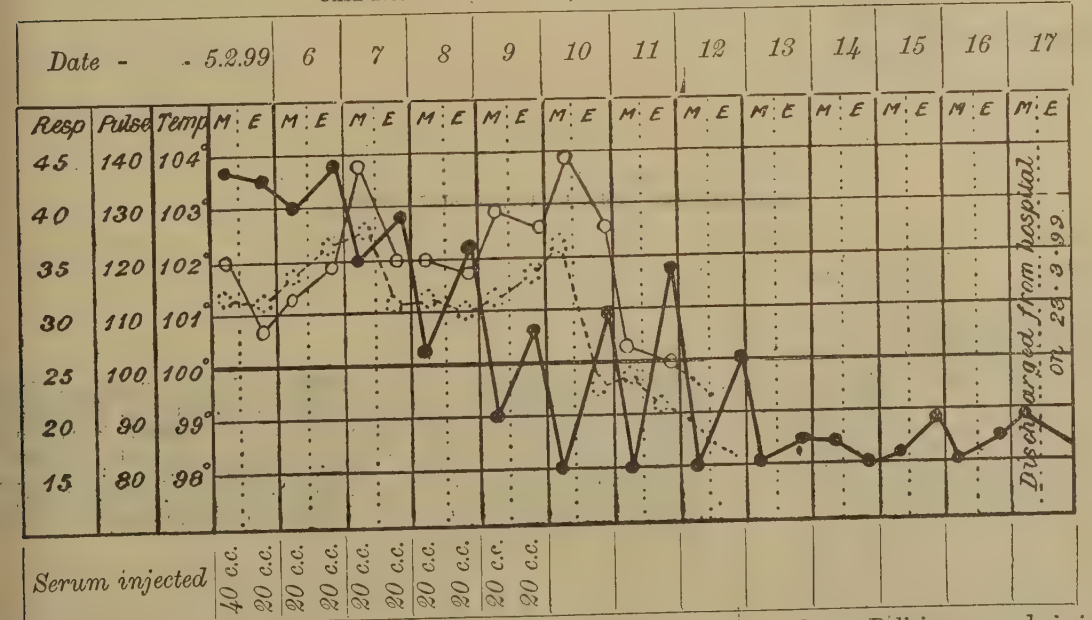
Luxman Rama. Male. Age 35. Hindu. Labourer. **3.2.99.**—About four days ago had a swelling in the right groin, which appeared suddenly, and has been acutely tender since its first appearance. There is a moderate sized bubo in the right groin. Skin has been cauterised over it. Pulse thready. Is conscious, but apparently moribund. Breath and extremities cold. Chest normal. 9.30 a.m.—40 *c.c. of serum.*

CASE No. VIII. (No. 1738 (Control No. 1740).)



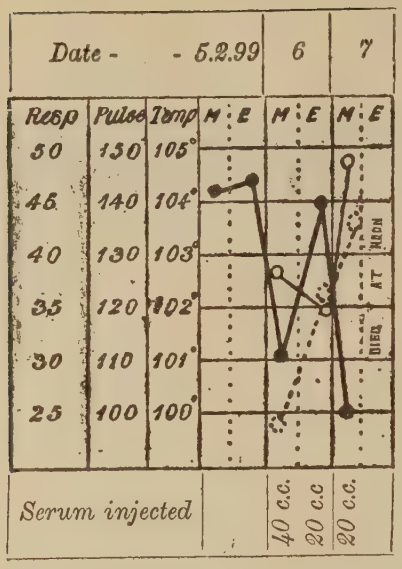
Dhondu Sadu. Male. Age 22. Hindu. Labourer. **4.2.99.**—Admitted with fever and bubo in right femoral region. Has been ill for two days. Eyes not suffused. Is quite conscious. Tongue covered with white fur. Pulse good. Second pulmonary sound, accentuated. Lungs: Patchy, moist sounds, mostly of left side. Much cough. Bubo size of a walnut. Very tender. Spleen not felt. Liver dulness, normal. 10 a.m.—20 *c.c. of serum*, No. 31. 5.30 p.m.—15 *c.c. of serum.* **5.2.99.**—Cough very troublesome. Pulse fair volume. General condition pretty good. 10 a.m.—40 *c.c. of serum.* 10 p.m.—20 *c.c. of serum.* **6.2.99.**—10 a.m.—Patient collapsed with cold extremities, and very feeble pulse. Rallied somewhat after injection of ether and strychnine. Became very bad again at 11 a.m. Much frothy sputum. Chest full of râles. Pulse imperceptible. 20 *c.c. of serum.* 6 p.m.—Moribund. 20 *c.c. of serum.*

CASE No. IX. (No. 1746 (Control No. 1739).)



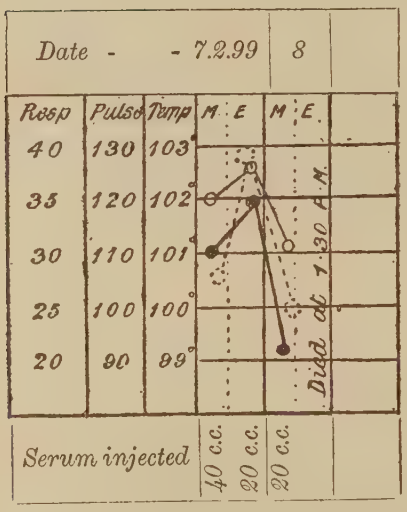
Rama Narayan. Male. Age 29. Hindu. Coolie. **5.2.99.**—Ill for three days. Delirious on admission, emperature 103·8°. Several contusions about face. Pulse, fair volume. Tongue dry, thick yellow fur. reath very fœtid. Eyes not suffused. No enlargement of liver or spleen. Bubo. A string of hard, rather nder glands in left femoral region. Heart and lungs, normal. 10 a.m.—40 *c.c. of serum*, No. 31. 10 p.m.— 0 *c.c. of serum.* **6.2.99.**—Slept fairly well. Conscious this morning. Pulse 120, weak. Has some cough. 0 a.m.—20 *c.c. of serum.* 6 p.m.—20 *c.c. of serum.* **7.2.99.**—Delirious at intervals. Pulse fairly good. 0 a.m.—20 *c.c. of serum.* 6 p.m.—Pulse not so good. 20 *c.c. of serum*, No. 21. **8.2.99.**—Quiet during the ight, but no sleep. Speech very thick. Cough and expectoration. Râles both sides of chest. 10 a.m.— 0 *c.c. of serum*, No. 21. 6 p.m.—Semi-conscious. 20 *c.c. of serum.* **9.2.99.**—Condition better. 10 a.m.— 0 *c.c. of serum*, 6 p.m.—20 *c.c. of serum.* **23.3.99.**—Convalescence slow.

CASE No. X. (No. 1762 (Control No. 1765).)



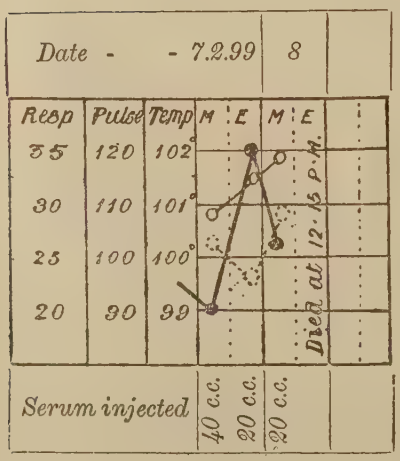
Dhondoo Bhanji. Male. Age 30. Hindu. Labourer. **5.2.99.**—Ill for two days. Admitted with fever and gland in right axilla. Patient is quite conscious. Tongue coated. Eyes injected. Speech slightly affected. **6.2.99.**—Patient is conscious. Speech markedly affected, the ends of words being much prolonged. Tongue tip protruded to left of mid line. No ocular or other paralysis. When talking, from time to time, there is a sort of spasm of the orbicularis oris, which stops his speech. Pulse, poor volume. Bubo in right axilla about size of walnut, very tender. Spleen not felt. Liver normal. Lungs: patches of pneumonia, both bases behind. Heart normal. When left alone, patient mutters incoherently to himself. 10 a.m.—40 *c.c. of serum*, No. 31. 6 p.m.—Condition unaltered. Pulse, very poor volume. 20 *c.c. of serum*. **7.2.99.**—Quiet all through the night. Delirious this morning. Condition very bad. Pulse, imperceptible at wrist. 10 a.m.—20 *c.c. of serum*. Died at noon.

CASE No. XI. (No. 1775 (Control No. 1776).)



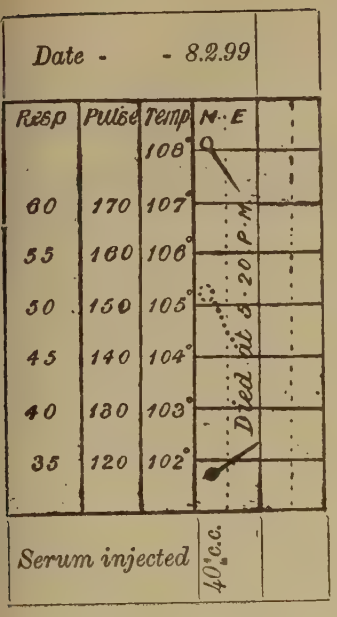
Narayan Ooma. Male. Age 14. Hindu. Peon. **7.2.99.**—Ill for six days. Fever and hard painful gland in left groin. Tongue coated in patches with dry yellow fur. Eyes not suffused. Speech slightly thick. Quite conscious. Heart, spleen, and liver, normal. Lungs. Patches of moist sounds posteriorly in both lungs. Pulse of poor volume. Bubo, size of a walnut. 11 a.m.—40 *c.c. of serum*, No. 31. 6 p.m.—Very weak. 20 *c.c. of serum*, No. 21. **8.2.99.**—No sleep. Very delirious all night. This morning is exhausted. Pulse imperceptible at wrist. Running in brachial artery. Extremities cold. 10 a.m.—20 *c.c. of serum*, No. 21.

CASE No. XII. (No. 1773 (Control No. 1752).)



Kalloo Parbutti. Male. Age 25. Hindu. Labourer. **7.2.99.**—Ill for two days. Admitted with fever and gland in right axilla. Dorsum of tongue covered with dry brown fur. Eyes injected. Speech not affected. Is quite conscious. Pulse poor volume, but regular. Heart, lungs, spleen, and liver normal. Much œdema around the bubo. 11 a.m. —40 *c.c. of serum*, No. 31. 6 p.m.—Pulse very poor. 20 *c.c. of serum*, No. 21. **8.2.99.**—Noisy delirium. Pulse almost imperceptible. 10 a.m. —20 *c.c. of serum*, No. 21.

CASE No. XIII. (No. 1786 (Control No. 1787).



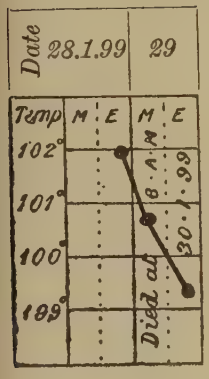
Sakharam Krishna. Male. Age 12. Hindu. Labourer. **8.2.99.**—Four days ill. Bubo, left axilla. Tongue coated. Speech not affected. Eyes somewhat injected. Heart normal. Lungs. Harsh breathing over whole of left chest. Liver and spleen, normal. Pulse, running about 180. 11 a.m. —40 *c.c. of serum*, No. 21. 5 p.m.—Had a short convulsive fit.

II.

CONTROL CASES, to those TREATED WITH ROUX' SERUM.

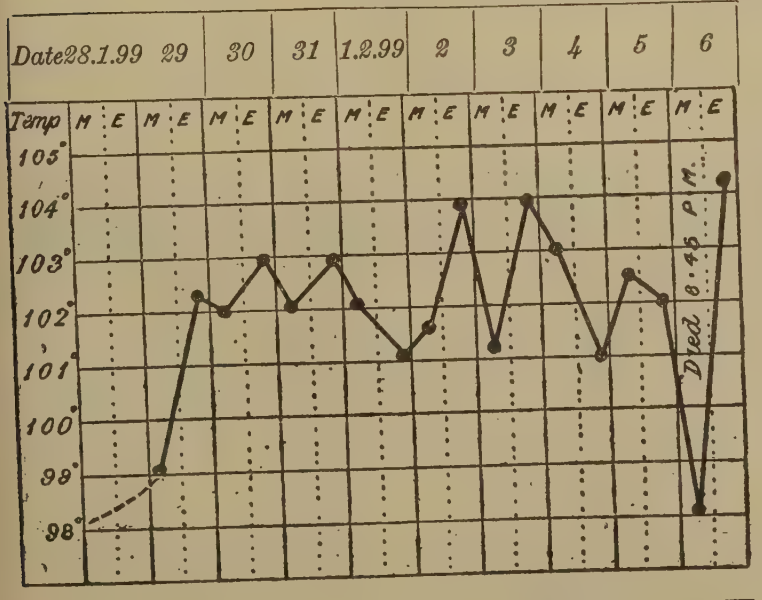
Total number - - -	13
Died - - - -	13
Percentage mortality -	100

CASE No. I. c. (No. 1664 (Control to No. 1656).)



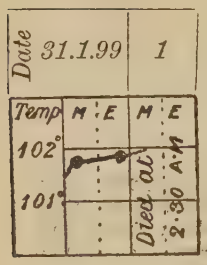
Anandroo Gennoo. Male. Age 20. Hindu. Labourer. **28.1.99.**—Ill for two days. Right femoral bubo. Tongue coated. Pulse very feeble. **29.1.99.**—Slept well. Pulse very feeble and rapid.

CASE No. II. c. (No. 1667 (Control to No. 1670).)



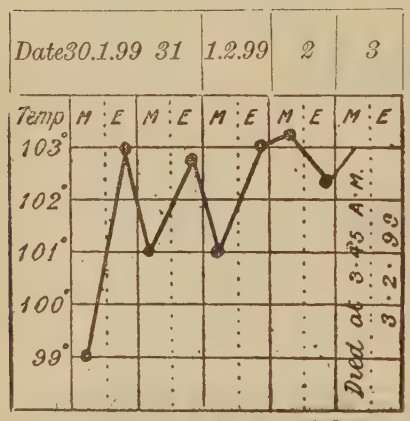
Luxman Yessoo. Male. Age 18. Hindu. Carpenter. **28.1.99.**—Ill for two days with fever, and painless hard swelling on the right side of the neck; says that the swelling is of long duration. **30.1.99.**—The swelling in the neck is becoming painful. Tongue coated. Eyes red. **1.2.99.**—Bubo about the same, still hard. **2.2.99.**—Small glands have appeared in both femoral regions. Patient very restless. **3.2.99.**—Had a fairly good night. Condition fairly good. **4.2.99.**—Is delirious this morning. Pulse of good volume. Cervical bubo incised, very little pus. **6.2.99.** —No sleep. Eyes much injected. Pulse fairly good in the morning.

CASE No. III. c. (No. 1690 (Control to No. 1686).)



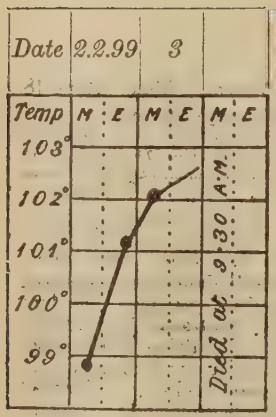
Dhondu Narayan. Male. Age 18. Hindu. Labourer. **31.1.99.**—Admitted to hospital with fever and gland in the right axilla. Semi-conscious. Speech affected. Tongue coated. Pulse very weak.

CASE No. IV. c. (No. 1675 (Control to No. 1697).)



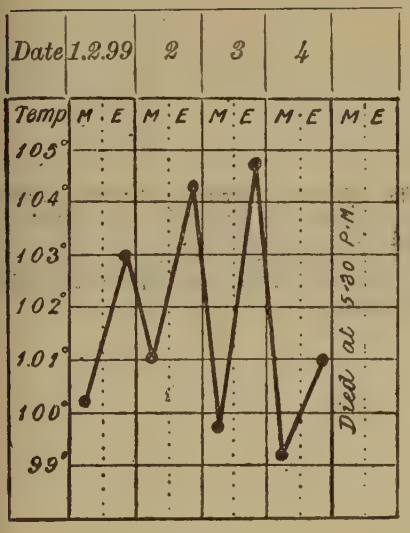
Madhoo Rama. Male. Age 25. Hindu. Polisher. **30.1.99.**—Ill for four days. Speech slightly affected. Small gland in right groin. Not tender. **31.1.99.**—Gland more prominent. **1.2.99.**—Delirious last night. Extremities rather cold. Tongue furred. Very noisy. **2.2.99.**—Slept well. Is quiet this morning. Pulse weak. Respiration hurried.

CASE No. V. c. (No. 1709 (Control to No. 1708).)



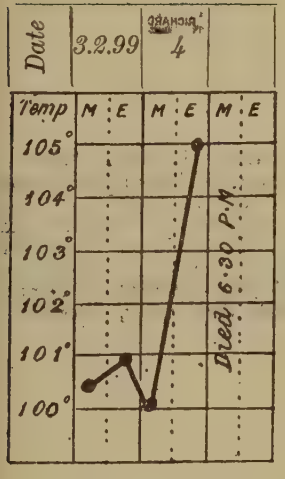
Barbosa. Male. Age 30. Christian. Servant. **2.2.99.**—Ill for six days. Admitted with fever and gland in left femoral region. Skin over the bubo is ulcerated. Tongue coated, eyes suffused. Bowels constipated. Speech somewhat affected. Pulse rapid and soft. **3.2.99.**—Pulse very feeble. Extremities cold. Very restless. Cannot swallow.

CASE No. VI. c. (No. 1699 (Control to No. 1716).)



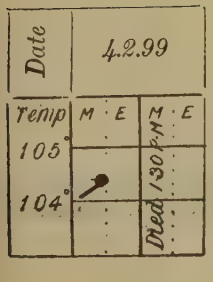
Takaram Babaji. Male. Age 40. Hindu. Carpenter. **1.2.99.**—Ill for two days. Has a cough, which he says is of long standing. Fever dates from two days ago. Tongue slightly coated. Has a chronic glandular enlargement in the right groin. **2.2.99.**—The glands are more painful. Pulse fair. **3.2.99.**—Restless during the night. Gland decidedly more painful and bigger. Pulse fair. **4.2.99.**—Cough troublesome. Delirious during the night. Pulse still fairly good.

CASE No. VII. c. (No. 1721 (Control to No. 1720).)



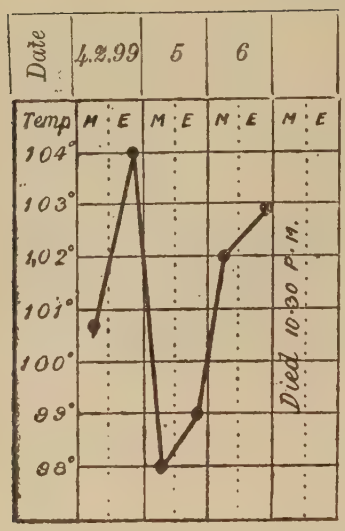
Bhaja Visram. Male. Age 15. Hindu. Labourer. **3.2.99.**—Ill for eight days. A swelling, in the right groin, appeared eight days ago, without fever. Was not painful at first. Four days ago, had fever, with slight shivering. Is now restless and delirious. Eyes injected. Tongue coated. Pulse very soft. Extremities cold. **4.2.99.**—Had no sleep. Pulse fairly strong. Tongue very coated. Appears to be more conscious.

CASE No. VIII. c. (No. 1740 (Control to No. 1738).)



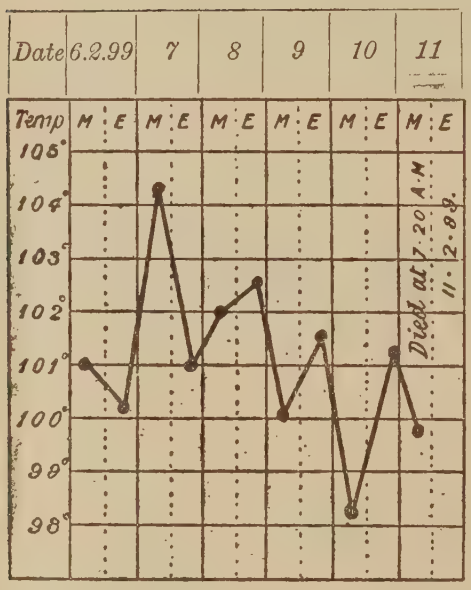
Ganoo Rawji. Male. Age 40. Hindu. Labourer. **4.2.99.**—Ill for six days. Admitted with fever and bubo in right axilla. Tongue coated. Eyes injected. Pulse feeble. Respiration hurried. Speech not affected. Slight hæmoptysis. Ecchymosis over chest and abdomen.

CASE No. IX. c. (No. 1739 (Control to No. 1746).)



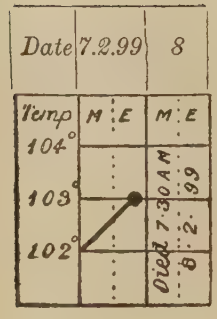
Dhakoo Bhikoo. Male. Age 25. Hindu. Labourer. **4.2.99.**—Ill for three days. Admitted with fever and bubo in left axilla. Is conscious. Tongue coated. Speech not affected. Eyes somewhat injected. Says that his fever began with rigors, and that he noticed the gland on the same day. Pulse rapid, but of fair volume. **6.2.99.**—Was noisy and delirious all night. No sleep. Pulse rapid and of poor volume.

CASE No. X. c. (No. 1765 (Control to No. 1762).)



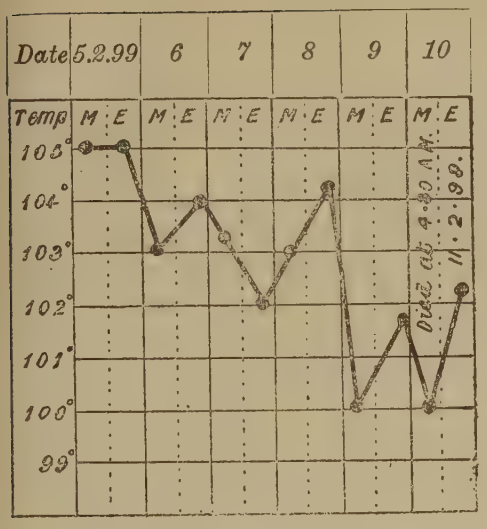
Takhoram Bhagu. Male. Age 9. Hindu. Labourer. **6.2.99.**—Ill for three days. Admitted for fever and bubo in right groin. There are two small glands, which are very tender. Speech somewhat thick. Pulse, soft and compressible. **7.2.99.**—Had no sleep. Delirious this morning. Very thirsty. Pulse very feeble. **8.2.99.**—Very restless and noisy, but slept up to 7.0 a.m. Pulse feeble. **9.2.99.**—More quiet to-day. **10.2.99.**—Was noisy and restless until midnight. Pulse very weak, extremities rather cold.

CASE No. XI. c. (No. 1776 (Control to No. 1775).)



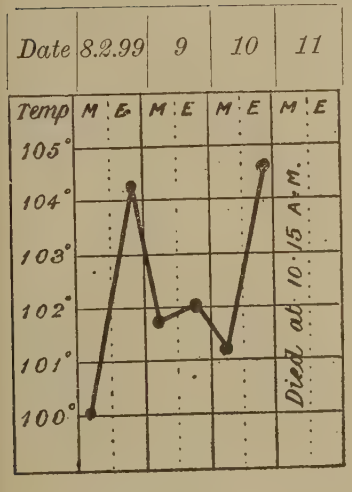
Dhanu Joti. Male. Age 40. Hindu. Labourer. **7.2.99.**—Ill for two days. Fever and gland in right groin. Tongue coated. Eyes injected. Some cough. Pulse soft and rapid. Bubo consists of three small painful glands.

CASE No. XII. c. (No. 1752 (Control to No. 1773).)



Ram Chandra Essoo. Male. Age 24. Hindu. Labourer. **5.2.99.**—Has been ill for three days. Fever commenced with shivering. Speech markedly affected. Is conscious. Spleen normal. **6.2.99.**—Tongue furred. Condition fairly good. **7.2.99.**—Complains of pain in the right groin, where there is a small bubo. Tongue coated. Pulse rapid and soft. **8.2.99.**—Noisy at times. Pulse weak. **9.2.99.**—Pulse bad. **10.2.99.**—Slept a little, but was restless during the past night. Pulse rapid and weak.

CASE No. XIII. c. (No. 1787 (Control to No. 1786).)



Korida Kristoo. Male. Age 18. Christian. Clerk. **8.2.99.**—Ill for two days. Fever and bubo in left axilla, which appeared last night, and is very tender. Tongue furred. Lungs clear. There was another plague case in the same house two days ago. Condition good. **9.2.99.**—Says the bubo is less tender. **10.2.99.**—Diffused swelling around the bubo. Tongue much coated. Pulse weak and rapid.

Letter No. 260A of 1898.

From W. M. HAFFKINE, Esq., C.I.E., to the SECRETARY TO THE GOVERNMENT of INDIA, Home Department, Simla.

Plague Research Laboratory,
SIR, Mazagaon, Bombay, June 7, 1898.

I HAVE the honour to forward a note by Surgeon Lieut.-Col. Warden, on the work done by him in this laboratory in connexion with the preparation of peptone from goat's meat, by digesting it in acidulated water.

As the result of this work, a preparation now entirely manufactured in the laboratory has been substituted for commercial peptone.

The following is the formula of that preparation:—

1,000 grammes of goat's meat mixed with 2,000 grammes of water and 150 c.c. of hydrochloric acid, and heated for 5½ hours in an autoclave under 2½ kilos of pressure.

The filtrate is mixed with 45 grammes of caustic soda and 75 grammes of common salt, heated further under two kilos of pressure for half an hour, filtered, and the volume of the filtrate brought, by addition of water, up to 3,000 grammes.

For the preparation of the medium in which the plague prophylactic is cultivated, one part of the above solution is mixed with nine parts of neutralised goat's meat extract, obtained by boiling fresh goat's meat in 18 volumes of water. The surface of the liquid is then covered with a thin layer of minute droplets of ghee (clarified butter).

The plague prophylactic is the result of a prolonged fermentation produced in the above medium by the plague bacillus, *plus* the bodies of the bacilli themselves killed by maintaining them for an hour at a temperature of 65° C.

2. Apart from the substitution of peptonised goat's meat for commercial peptone, no modification is, for the present, introduced in the preparation of the plague prophylactic, as adopted after the tests in the Byculla House of Correction and the Umarkhadi Common Jail, in Mora, in Damaon, Bombay, Lonaula, Kirkee, Undhera, and in the Bombay Khoja community.

The observations collected in the above epidemics have demonstrated that the plague prophylactic possesses the two properties which were aimed at in our programme, viz., the power of reducing the number of attacks amongst the inoculated, when compared with uninoculated, and the power of reducing the number of deaths in inoculated attacked, when compared with the attacked uninoculated. The observations have shown that the two effects combined amount to a final reduction of between 80 and 90 per cent. of death in inoculated, when compared with the uninoculated exposed to the same epidemic.

These properties of the plague prophylactic may now be considered as an established fact which is not likely to be shaken by any further tests or experiments; and no sudden alteration in the nature of the drug is desirable. This is because it is impossible to say for certain whether the above results were obtained just in the way I imagined they would, and in answer to the theoretical conjectures which guided me. Future alterations and improvements must be made gradually, and in conformity with those conjectures, which will be confirmed or refuted only by a critical scrutiny of results.

In the course of my observations on the inoculated against cholera I formed the idea that the invasion of an individual by morbid microbes is very effectively controlled by a treatment with preparations made of the bodies of microbes, but that the issue of the disease when invasion has not been prevented is not influenced by such a preparation. On the other hand, the fact that almost in all infectious diseases, studied up to now, the morbid organism remains present in the patient for a long time after recovery, without causing any inconvenience, goes to show that recovery is a phenomenon essentially different from the resistance to microbial invasion, or from the ridding of the body of such microbes after invasion.

The strengthening of the organism for a struggle against morbid symptoms should be sought for in a treatment with preparations made from the products of microbes, not from the bodies of the microbes themselves.

Confirmation or otherwise of these views may result from cautious attempts at improving the results of the plague inoculation.

For the present the plague bacilli introduced into the fermentation medium are permitted to grow there for an average of four weeks; after this they are killed, but left in liquid. The mixture combines at once a large amount of bodies of microbes, corresponding to the vaccines used in cholera, with the products secreted into the liquid, which are not present in the cholera inoculation. In the interest of the last ingredient it is desirable that the fermentation should be maintained as long as possible, much longer than the period given above, and extended, if possible, for months; in the interest of the microbial preparation, on the contrary, the cultivation should be as young and vigorous, and as unaltered by age, as possible.

The method at present used was selected as presenting a great simplicity of execution; and the period of four weeks was taken as being an average not so long as to cause a complete deterioration of the microbes, and yet long enough for the accumulation of a certain amount of fermented products.

The first step for improving this preparation should consist in separating the above two operations, viz., in cultivating fresh microbial vegetation separately, in a way similar to that used in cholera, and in maintaining, apart from this process, a fermentation in liquid media for periods longer than it is possible at present. The mixture of the two materials should be made artificially, and the result of the modification carefully studied in epidemics. The addition of fresh crops of microbes should reduce further the number of cases, while the use of cultures of older age should increase the resistance to the symptoms of the disease.

The problem of reducing the discomfort caused by the preventive inoculation, may possibly be solved by modifying the vaccine. It appears that, of the two elements constituting the present plague prophylactic, the liquid part, filtered or decanted off the solid residue, causes the rise of temperature observed after inoculation; while the solid part suspended in the liquid is responsible for the pain developing in the seat of inoculation. Under the effect of chemical and physical agencies the liquid loses its power of producing fever. On the other hand, it is possible that the solid residue may be modified mechanically or by dissolving it in chemicals, so as to cease to cause the local reaction. Whether such modifications are compatible with the maintaining of the protective power of the prophylactic can be solved only by direct observation, and by cautious and gradual attempts.

Lastly, an important problem in connexion with the manufacture of the prophylactic consists in fixing the pathogenic properties of the microbe so as to ensure uniform and accurately measurable effect. This has not been done up to now, chiefly on account of the difficulties of procuring animals, and in the interest of simplicity in the operations; but as this prophylactic does not contain living microbes, and is a fixed chemical drug, it was sought to compensate the alterations in the fermenting organism by modifying the doses of the drug. The result obtained with the weakest material up to now used amounted to the suppression of 77·9 per cent. of deaths in inoculated compared with the uninoculated, as was observed in the outbreak in the native followers of the Artillery at Kirkee.

Although, therefore, the plague prophylactic admits, and, it is to be hoped, will for a long time continue to admit, of many useful modifications, it may be considered that the question at issue has been, for practical purposes, solved by the experiments and observations made up to now; and I have no hesitation in recommending as wide an encouragement of the adoption of the method as possible, with the understanding that the treatment is optional, and offered as a voluntary substitute for the separation of the sick and healthy, and their removal from the place of habitation.

I have, &c.
Sd. W. M. HAFFKINE.

APPENDIX No. LXXXIII

STATEMENT HANDED IN BY M. HAFFKINE

REGARDING THE

ANTI-PLAGUE PROPHYLACTIC.

(This Statement is published at Mr. Haffkine's desire.)

On the 7th June 1898 I addressed to the Government of India a letter, No. 260A, in which the following three problems were put down in connection with the further development of the inoculation against the plague :—

(1) The first referred to the separation of the manufacturing of the bodies of the plague bacilli and of the metabolic substances, the mixture of which constitutes the plague prophylactic ;

(2) the second to the mitigation of the local effect caused by the inoculation ; and the third to

(3) the fixing of the properties of the plague bacilli so as to permit of a more accurate standardizing of the prophylactic.

The above problems, as well as several others, were early recognised as urgent in the Plague Research Laboratory. Unfortunately, the rapid spread of the epidemic, and the necessity of meeting the demands for prophylactic while the epidemic lasted, entailed such an amount of current work that, up to the present time, I was unable to sufficiently attend to their solution, though many attempts in the above direction have been already made in my Laboratory. I have requested now the Government to kindly give me a senior Assistant, to whom I could delegate the administration of the current Laboratory work, and thus be set free to attend to further inquiries. I have fair reasons to hope that the above request will be granted, and the problems mentioned above will be persistently and carefully pursued.

Among the problems enumerated I have not mentioned the one announced to the public by the Medical Officers at Hyderabad, the reason being that that problem of keeping the material free from common microbes is one that has been always the object of much care in the Laboratory. The Commission, however, knows that to attain that object in a complete form is not always feasible, and that such a state of affairs is not fraught with danger. Thus, for instance, there is no possibility of having a vaccine lymph for small-pox free from foreign microbes. The lymph taken direct from a vesicle of a calf almost without exception contains already extraneous microbes, that can be seen under the microscope and cultivated in nutritive media. When the lympth is squeezed out of the vesicle, it comes further in contact with the surface of the calf's skin, and with all the microbes adherent to it. These microbes cannot be killed in vaccine lymph, which is itself a living matter, as by doing so, the lymph itself is killed. The only thing that can be, and is done, is to prevent the foreign microbes from multiplying in the material, and this is to a great extent obtained, for instance, by the addition of glycerine to the lymph. The result, of course, is perfectly satisfactory. Every one has seen frequently in this country, in villages, batches of 200—300 children at a time, paraded in the streets with their vaccinated arms outstretched before the Inspectors of Vaccination, without a single case of complication due to those common germs being observed.

The plague prophylactic admits of being prepared with a far greater freedom from those common microbes than is the case with the vaccine lymph. To attain, however, this object fully, better conditions of work are required than those that we could command up to late. We had to work in the Laboratory with a staff of subordinates that were not prepared for bacteriological work, and with materials and appliances that we had to buy urgently at Bhendi Bazar, and at Abdul Rahman Street in Bombay. The Government Medical Stores did their utmost to procure for us supplies. At one time, however, they were able to get for us only bottles for which no corks of suitable size could be got; and afterwards, when the corks became plentiful, there were no more bottles in Bombay to suit fittingly the corks. Into a large number of such bottles common microbes penetrated after the material had been corked and sealed, owing to their deficient corking and sealing. In other instances, among the bottles prepared and sterilized for being filled up with the prophylactic there were such as had escaped complete sterilization. For effecting such, it is necessary that the temperature in the steam sterilizer should be raised 10° to 15° C. above the boiling point. Whenever, owing to the defect in the registering apparatus, or to other reasons, the bottles are subject to a lower temperature, complete sterilization is not effected. This, however, is no source of serious risk. Every one knows, for instance, that a surgeon preparing for an operation on a patient is perfectly safe if he keeps his instruments for a quarter of an hour in boiling water. No surgeon ever sterilizes his instruments at a higher temperature. The reason of this is that the temperature of boiling water kills all *pathogenic* microbes, capable of causing diseases ; and though the instruments, when taken out of the water and put into cultivation media, will always show a number of living germs sticking to them and which have escaped the effect of boiling, these germs are harmless, as are harmless all those innumerable microbes that we eat and drink and breathe in our daily life, or as is harmless an apple, or an onion, or a mango, or any other living vegetable or fruit that we eat uncooked.

Whenever, therefore, steam is formed in the sterilizer, and the bottles remain there, be it for a quarter of an hour only, they become safe as to the risk of having in them microbes causing disease ; but if the temperature is not raised high enough *above* that point, there will remain common microbes in those bottles and they may be found subsequently in the prophylactic put into those bottles. Such microbes will be capable of growing when transferred into cultivation media ; as an apple is capable of growing when put into the soil. In a number of cases these microbes will be killed by the ½ per cent. of carbolic acid contained in the prophylactic. There are other microbes that will not be killed by that antiseptic, but their growth and multiplication will be arrested, as glycerine arrests the growth of microbes in vaccine lymph, which is all that is required in the case. But some microbes resist even that effect, and it is the latter that it is desirable to avoid. This can be done sucessfully and very easily in ordinary quiet times, and even in times of urgent and hasty work when the Laboratory gets fully officered, and all the officers get to know their work. During the last epidemics in Hubli, Dharwad, Gadag, Bangalore, those were not the conditions that obtained, and we had to consider whether we were justified in doing our work and supplying urgently those places with prophylactic under the then existing conditions or not. We decided that we were, and I have no doubt every

one will share our view when it is considered how much the facts justified our calculations. This can be easily done from any concrete instance.

The Commission have it on evidence from the medical officers who were in charge of the plague operations at Hubli, during the last epidemic there, that they performed 78,000 injections with the plague prophylactic in that town alone, and that in these operations they observed 12 cases where the injection caused complication in the shape of abscesses. All these 12 abscesses subsequently healed up, and no complications of any other nature have ever occurred —in this respect they were perfectly emphatic. The facts collected in Hubli show that the total number of deaths that took place there during the epidemic was 2,755; but that if no inoculation had been done, and the death-rate in the whole population had been equal to that observed in the uninoculated, 24,899 would have died. The inference is that the inoculation with the plague prophylactic saved 22,144 lives. In adopting the plan of work which the best of our knowledge suggested to us as correct and safe, the officers of the Plague Research Laboratory admitted the risk of causing *one* abscess that subsequently healed up, for each 1,835 lives that they have saved.

I beg, however, the Commission to believe me that we are doing our very utmost to avoid even the possibility of that *one* abscess.

In conclusion, permit me to express my regret, if it so happened that the Hyderabad Medical Officers, who startled the public by their statements and deterred a very large number of unknowing people from taking advantage of inoculation, had the requisite knowledge for estimating the above considerations, but represented the case to the public in an incomplete form. On the other hand, I have no reproach to address to them if they acted when being themselves under a misapprehension.

(Signed) W. M. Haffkine.

APPENDIX No. LXXXVI.

The following abstract of the evidence, which he was prepared to give before the Indian Plague Commission, was submitted by Brigade-Surgeon Lieutenant-Colonel D. D. Cunningham, I.M.S., M.B., F.R.S., C.I.E., and as the witness was unable, through ill-health, to appear for examination, it is published as an Appendix to the Proceedings of the Commission.

I can say little regarding the clinical phenomena presented by the individuals who were supposed to be suffering from plague in Calcutta in the latter part of the year 1896. The number of suspected cases was very limited and the only ones which I saw were some men of the Shropshire Regiment, who were suffering from chronic inguinal and femoral buboes similar to those which were on record as having been of periodic occurrence in the Station Hospital for many years previous, and a case in the Howrah Hospital, which was suspected because the patient had recently returned from Bombay, but which, by observers better qualified to form an opinion regarding it than I was, was regarded as presenting a history and clinical features indicative of venereal origin.

I had, however, ample opportunity of examining the question from a bacteriological point of view, the materials at my disposal being of the following nature:—

I. Type-specimens of cultivations of plague bacilli from Bombay, supplied by Messrs. Haffkine and Hankin.

II. Type-specimens of cultivations derived from the blood of cases of disease in Calcutta and the neighbourhood and supposed by some observers to demonstrate the presence of the plague bacillus.

III. A corresponding series of microscopic preparations of blood and the growths in cultivations.

IV. Cultivations and preparations of blood personally obtained from suspected cases of disease in Calcutta.

V. Specimens of dead and moribund rats from Calcutta and cultivations and microscopic preparations derived from their organs and blood.

The materials, which were supplied by the Health Officer of Calcutta as specimens of growths of plague bacilli from the blood of cases of disease in Calcutta, consisted of cultivations of various distinct species of schizomycete organisms, but none of them presented the distinctive features, either macroscopic or microscopic, of growths of the plague bacillus, and the majority were unequivocally results of aërial contamination, as was clearly demonstrated by the results of a series of experiments in which specimens of the blood of various species of animals were exposed to the influence of contact with the air of the laboratory, in which I was working, for periods of longer or shorter duration. The following example will serve to illustrate the nature of the procedure adopted and the results obtained in these experiments:—

Specimens of blood were drawn directly from the jugular vein of a healthy fowl into two sterilised test-tubes plugged with cotton wool. One of the tubes was kept continuously plugged during a period of three weeks' duration without showing any signs of the presence of any schizomycete contamination; the coagulum contained in it never underwent any contraction, save the small amount incident on evaporation, the formed elements remained well preserved throughout, and cultivations and microscopic preparations, derived from it at the close of the period, failed to yield any evidence of the presence of any schizomycete organisms. The blood in the other test-tube was, shortly after it had been obtained, decanted into half-a-dozen sterilised watch-glasses, which remained exposed to the air for about twenty minutes and were then enclosed within a sterilised moist chamber. Decomposition rapidly set in in all the specimens and, within the course of a few days, the latter yielded abundant growths of various schizomycetes—two species being identical with and subsequently yielding pure tube-cultures of two of the so-called plague bacilli supplied by the Health Officer. The other specimen of blood was eventually exposed in watch-glasses in similar fashion and yielded like results.

The microscopic preparations of blood and of corresponding cultivations obtained from the Health Officer in no case showed any satisfactory evidence of the presence of any true plague bacilli. Certain of the preparations of blood did contain schizomycetes, but these had the form of elongated rods, and in one instance were common large aërial putrefactive bacilli. No fixative had been employed in the preparation of the specimens of blood, and consequently fragments of chromatin abounded in most of them, and may have been mistaken for schizomycete organisms. Some of the preparations, which were labelled as having been derived from the blood and tissues of a rat, which had died in consequence of inoculation of a cultivation of blood derived from a suspected case of plague, certainly did contain numerous schizomycetes, but, as these did not present the characters of plague bacilli, and as the material injected had consisted of 1 c.c. of decomposing broth, or an amount equivalent to about 300 c.c. for an ordinary human adult, neither the fatality attending the procedure nor the presence of schizomycete organisms in the blood and tissues of its victim can be regarded as of any special significance.

The microscopic preparations and cultivations of blood which I myself made were derived from the suspected cases of plague already alluded to as having been personally inspected, and in not a single instance afforded any evidence of the presence of schizomycete organisms of any kind; the specimens of blood were of perfectly normal character, and the cultivations remained, without a single exception, absolutely sterile.

There can be no question that there was a considerable amount of mortality among common house-rats for some time in certain parts of Calcutta during the latter part of 1896, and this was, not unnaturally, regarded by those who affirmed the existence of plague in the city as a strong confirmation of the correctness of their view. Very much stress cannot, however, be laid on the phenomenon of the occurrence of destructive epidemics among rodents unless the precise nature of the disease have been unequivocally demonstrated. Anyone who has had any practical experience of gardening in Calcutta must have had ample opportunity of observing the extraordinary fluctuations in the number of common palm-squirrels and Indian mole-rats — *nesocia bengalensis* — which periodically recur and which can apparently be only accounted for as the result of fatal epidemics on a very large scale. During the earlier half of the decade, 1880–89, the numbers of both these rodents was very great, and latterly so excessive as to be the cause of much damage. An abrupt and excessive decrease followed, and for some years both species were very rare; this was succeeded by a gradual increase, and by the year 1896—the last complete year which I spent in Calcutta—the numbers of both species had once more become troublesomely high. I had an experience of the actual occurrence of a similar epidemic in the forest clothing the slopes of

Mainom—a mountain in Sikkim—in the autumn of 1889, when, in the course of one day's march between the Yangong and Ralong Gompas, I was able to collect a whole series of fine fresh specimens of either *mus fulvescens* or *mus jerdoni*, which were lying dead and scattered along the track. The facts that, according to Babu R. B. Sanyal, the Superintendent of the Zoo in Alipur, a considerable mortality among house-rats is not by any means an unusual phenomenon in the early part of the cold weather in Calcutta, and the abrupt disappearance of the epidemics of field-voles which occasionally occur in this country and other parts of Europe, and which can only, apparently, be accounted for in like fashion, afford additional evidence that the mere occurrence of destructive epidemics among the rodents of a locality does not in itself afford any satisfactory evidence of the presence of plague or of conditions adapted to give rise to the disease there. The phenomenon was, however, sufficiently suspicious to demand special inquiry, and a careful examination was accordingly made of dead and dying rats obtained from the part of the town in which the epidemic prevailed. The results were not of a nature to encourage a belief that the animals were affected by plague. There were no evidences of any special glandular affection beyond the presence of a very large number of coccidia in the liver, and numerous cultivations of the blood and of materials derived from the lymphatic glands and other organs, although in many instances yielding growths of various kinds, failed to give any characteristic of the plague bacillus.

From the above data it is evident that, in so far as my experience went, there was no evidence of the existence of any disease presenting the bacteriological phenomena of plague in Calcutta in 1896.

April 19th, 1899. D. D. CUNNINGHAM.

APPENDIX No. LXXXVII.

(*See* Question No. 7269.)

Additional Note to Dr. Clemow's Evidence.

The following are the additional details of the second tance, given in my evidence, of a second attack of gue occurring in the same person:—

The patient was a Hindu, female, whose first attack plague occurred in October 1897, when she was ated in the Arthur Road Hospital. With some ficulty I succeeded in tracing her case-sheet, and nd that she was admitted to the hospital on tober 16th, 1897. She is described as aged 10 (on case-sheet in the Parel Hospital her age is given 12). There was a bubo in the left groin, involving h the femoral and inguinal regions; the swelling s deep-seated, and there was much infiltration round On two occasions the temperature rose to 105°. ere is no note in the case-sheet as to whether the bo suppurated or was incised. The temperature rve was an irregular one, varying between 98° and °. She was transferred to the Parel Hospital on vember 16th. Her case-sheet there contains no ther details. She was discharged on December 13th.

The second attack occurred in April 1898. The details of this attack have already been given in my evidence. It is noteworthy that in each attack the bubo was in the left groin. The facts of the case, given in my evidence before the Plague Commission (*see* Question No. 7261) may be repeated here, for facility of reference, and are as follows:—

Case II.—Register No. 1060.—Hindu female, æt. 12, was admitted to the Parel Hospital on April 12th, 1898, with symptoms of plague. It was ascertained that she had had a previous attack of plague five and a half months earlier; she had been treated in the Arthur Road Hospital, Bombay, and had been transferred as a convalescent to Parel in December; her first discharge from the Parel Hospital was dated 13th December 1897. The second attack in April was a severe one; there was a left inguinal bubo, from which plague bacilli were isolated. She died on 14th April, 47 hours after admission, and 55 hours after the onset of symptoms.

APPENDIX No. LXXXVIII.

CORRESPONDENCE WITH W. M. HAFFKINE, ESQ., AND THE GOVERNMENT OF INDIA, REGARDING THE CORRECTNESS OF FIGURES CONCERNING INOCULATION IN THE BOMBAY JAILS, SUPPLIED TO THE INDIAN PLAGUE COMMISSION.

I.

On August 14th, 1899, Mr. Haffkine wrote to the President of the Indian Plague Commission, calling attention to correspondence published in the "Times," in which it was stated that "the impression left on the minds of many" was that Mr. Haffkine's statistics regarding prophylactic inoculation "are somewhat inaccurate." He continued: "In case, therefore, you, "or any member of the Commission, entertain any "doubt, or have any difficulty as to my reports on "inoculation, I should like, as I requested several "members of the Commission in India, that an "explanation be asked from me before your Report is "made public." Upon this, the following correspondence took place:—

II.

Letter from the Secretary to the Indian Plague Commission to W. M. Haffkine, Esq., C.I.E., dated India Office, 31.8.99.

SIR,

IN reply to your letter of the 14th August, 1899, to the President, I am directed to say that if you are anxious to make any further explanations regarding the statistics given in your own reports and evidence regarding inoculation, the Commission will be glad to receive them verbally from you on September 12.

2. I am at the same time to say that certain points of difference between your own evidence and reports and the evidence of other witnesses has attracted the attention of the Commissioners. The enclosed memoranda (A. and B.) of the official figures contain particulars of these differences, and the Commissioners will be glad to receive in writing anything you may desire to convey to them before September 7th.

3. The Commissioners will be glad to learn, when you reply to this letter, whether you wish to appear before them on September 12th or not. In case you do, I am to request that you will be present at the room occupied by the Commissioners in the India Office at 2.30 p.m.

MEMORANDUM B.

HER MAJESTY'S COMMON PRISON, UMARKHADI, BOMBAY.

The inoculations were done on the morning of January 1st, 1898.

According to Mr. Haffkine's figures, at the time of inoculation, the total population of the jail was 402, of whom 201 were inoculated; the official figures† show a population of 399, of whom 199 were inoculated.

According to Mr. Haffkine's figures, among those who were in jail on January 1, 1898, 10 of the non-inoculated got plague, of whom six died, while three of the inoculated got plague, none of the cases being fatal.

According to the official figures, it appears that 20 prisoners in all got plague. Of these four non-inoculated prisoners and one inoculated prisoner should be left out of consideration as they were not in jail on January 1, 1898, while three prisoners were attacked before the inoculations were done. Of the remaining 12 prisoners who got plague nine were not inoculated, and five of them died, while three were inoculated, among whom none died.

† *See* App. No. LIX. in this volume.

III.

From W. M. Haffkine, Esq., C.I.E., to The Secretary, Indian Plague Commission, Whitehall, London, dated London, 9th September 1899.

Sir,

I have the honour to acknowledge with thanks the receipt of your letter, dated India Office, 31st August 1899, which reached me in Paris. I am glad that my letter to the President, of the 14th August, elicited the information, of which I was not aware, that there existed any discrepancy between mine and "the official" figures referring to the plague in the Byculla and Umarkhadi Jails in Bombay, though my being separated from my office records prevents me from substantiating my explanations as fully as I should desire.

The following is the analysis of the discrepancies pointed out in the appendices to your letter, so far as the materials at my disposal here permit me of analysing them.

Byculla House of Correction.

(*a.*) The number of attacks and deaths of plague to January 30th, 1897, inclusive, is uninoculated: my figures—15 and 8; "official figures"—14 and 7.

My figures represent the number of the following prisoners, whose names and particulars were supplied to me by the authorities of the House of Correction:—

Biva Bagu, prisoner, No. 977, admitted to hospital for plague on 25.1.97, died on 27.1.97.
Rama Gobin, prisoner, No. 1093, admitted to hospital for plague on 26.1.97, died on 30.1.97.
Ganu Baloo, prisoner, No. 1242, admitted to hospital for plague on 27.1.97, died on 31.1.97.
Ramgulab Rampratab, prisoner, No. 1094, admitted to hospital for plague on 27.1.97.
Narain Dondu, prisoner, No. 1359, admitted to hospital for plague on 27.1.97, died on 30.1.97.
Adamji Alibai, prisoner, No. 1349, admitted to hospital for plague on 27.1.97.
Katoo Lakmidas, prisoner, No. 1235, admitted to hospital for plague on 27.1.97.
Anton Salvador, prisoner, No. 1247, admitted to hospital for plague on 27.1.97.
Balkishna Madu, prisoner, No. 1272, admitted to hospital for plague on 27.1.97, died on 30.1.97.
Syed Junas Ali, prisoner, No. 1336, admitted to hospital for plague on 30.1.97.
Jiwa Virchand, prisoner, No. 1144, admitted to hospital for plague on 30.1.97.
Hussein Mahomed, prisoner, No. 1276, admitted to hospital for plague on 30.1.97.
Visram Jairam, prisoner, No. 1310, admitted to hospital for plague on 30.1.97, died on 5.2.97.
Valichand, prisoner, No. 1312, admitted to hospital for plague on 30.1.97, died on 3.2.97.
Ranji Jotie Pawa, prisoner, No. 1129, admitted to hospital for plague on 30.1.97, died on 1.2.97.

I am quite unable to explain, without an inquiry at the House of Correction, how, after having supplied me with the above details, which they knew were required by me for an official report to Government, the authorities could have given the above "official figures" of 14 and 7. The discrepancy should be the easier to clear up that it refers not to a mild or doubtful case, but to a case which ended fatally.

(*b.*) Same item, referring to inoculated: my figures 3 and 3; "official figures" 0 and 0.

My figures refer to the following three inoculated prisoners:—

Govinda Pandu, No. 1222.
Keishoo Umar Shunkar, No. 672.
Abdul Karim Gulam Hussein, No. 1356.

They were inoculated, together with the other 154 prisoners in the evening of the 30th January 1897. During the day of the 31st and part of 1st February, all had fever, but whereas in the others the fever disappeared or subsided towards the evening of the 1st, the above three had still high fever on the morning of the 2nd, and were taken to the hospital, where they were found suffering from painful glands. They were at once admitted as plague cases, and entered as such in the Jail Hospital book, under the date of admission. But Mr. King, Assistant Surgeon, on duty at the House of Correction, and myself, went to take notes of the symptoms of the patients, and found that:

Govinda Pandu, who had been inoculated in the left flank on the 30th January, had a painful bubo in the left axilla, which he felt since the evening of the 30th January, but *subsequent* to inoculation.

Keishoo Umar Shunkar, who had been inoculated in the right flank, had a painful bubo in the left groin, which he felt since the day of inoculation, *previous* to being inoculated; and

Abdul Karim Gulam Hussein, who had been inoculated also in the right flank, had a painful bubo in the left armpit, which he felt since the evening of the 30th January, *subsequent* to inoculation.

The details, of which I took at the time very careful notes, as they had a very great importance with regard to the question as to the time which the inoculation would take to exercise a protective effect, will certainly be found reproduced also in Mr. King's clinical notes which he kept at the time of the outbreak. The Jail Hospital tabulated registers have, I believe, a column for the date of admission of patient to the hospital; and the patients, in the Byculla House of Correction, during the outbreak of 1897, were admitted to the Plague Hospital shed only after the fact of their suffering from plague became clear, which, in some instances, was a day or two after the appearance of initial symptoms. During this undecided period the patients were kept in an observation ward; but with regard to the above-mentioned question, viz., the length of time which the inoculation required for preventing the occurrence of an attack in an inoculated individual, the date of the appearance of those initial symptoms, and not of the admission of the patient to the Plague Hospital, was of importance, and that is why I stated that Govinda Pandu, Keishoo Umar Shunkar, and Abdul Karim Gulam Hussein were attacked on the 30th January 1897, when their glands, which subsequently developed into actual plague buboes, first appeared, and not on the day when they were admitted to the plague shed.

(*c.*) Strength of jail population on 30th January 1897: my figures, 183 uninoculated and 154 inoculated; "official figures," 185 uninoculated and 153 inoculated.

Unfortunately I have not with me here the nominal list of the inoculated in the House of Correction of 30th January 1897; but I have with me a table which I made out on the 8th February 1897, together with Mr. Hall, the Superintendent of the Jail, in his office, from the jail books, and which shows that, excluding the prisoners already taken to the Plague Hospital, the numbers of inoculated and uninoculated were:—

In the evening of the 30th January 1897, when the inoculations where done, 154 and 183; on the mornings of—

January 31, 1897, 151 and 177;
February 1, 1897, 150 and 172;
February 2, 1897, 146 and 173;
February 3, 1897, 176 and 172;
February 4, 1897, 146 and 171;
February 5, 1897, 146 and 169;
February 6, 1897, 146 and 169;
February 7, 1897, 146 and 165; and of
February 8, 1897, 146 and 161.

(*d.*) January 31st, 1897, cases and deaths in inoculated: my figures, 1 and 0; "official figures," 0 and 0.

My figures refer to the prisoner Rama Luxman, No. 832, inoculated on 30th January 1897 in right flank, who was admitted to the plague shed on 1st February 1897, but had a painful bubo in the right axilla since the previous day. On account of the reasons above mentioned under paragraph (*b*) he is entered in the Jail Hospital register under the date of the 1st February 1897, and in the laboratory books under the date of January 31st. These details will, undoubtedly, be found also in Mr. King's clinical notes, as all my rounds in the jail were made in the company of the jail authorities, and my information obtained through their own inquiry made in my presence.

(*e.*) February 1st, cases and deaths in inoculated: my figures, 0 and 0; "official figures," 4 and 3.

The explanation of the discrepancy is given in the above paragraphs (*c.*) and (*d.*).

(*f.*) February 2nd, cases and deaths in inoculated: my figures, 0 and 0; "official figures," 1 and 0.

The official figures refer to prisoner Ganpat Babajee, No. 1336, inoculated on 30th January 1897, in the evening.

He was discovered at 5 p.m. of the 2nd February, with a temperature of 102° Fahr., and was admitted to the plague shed; but next morning was free from fever. During the day of the 3rd February he complained, however, of pain in the lower jaw, but no swellings

could be found there; and the pain disappeared during the day of the 4th.

In informing me about this case, the authorities of the jail stated that Gunpat Babajee suffered from 12 hours of fever, that certainly it could not have been a case of plague, but that he had been entered into the books as admitted into the plague shed, and that it was impossible to make any corrections there.

(*g.*) February 4th, cases and deaths uninoculated: my figures, 1 and 1; "official figures," 0 and 0.

My figures refer to prisoner Mahomed Hussein, No. 988, who undoubtedly, by an error, is placed in the "official figures" for the same date among the inoculated.

Unfortunately, as mentioned above, I am unable to find among the notes I have with me here, a nominal list of the prisoners who were inoculated in the Byculla Jail on the 30th January 1897. Such a list does exist in the Laboratory Office in Bombay, and the fact of inoculation must also have been entered in the jail ticket of the inoculated prisoners. But I cannot conceive any possibility of a mistake on my part on the point in question. I have with me here a copy of my report, dated 15th February 1897, to the Secretary to the Government of India in the Home Department. In the list of plague occurrences in the jail it is stated, referring to the 7th of February:—"On the 5th day "after inoculation there were, amongst 171 non-inocu- "lated, 1 case which proved fatal: amongst 146 inocu- "lated, nil." When sending the above report to the Home Secretary, I sent a copy of it also to Mr. C. P. H. Snow, I.C.S., Municipal Commissioner of Bombay, who asked also for a report from Lieut.-Colonel Waters, I.M.S., the medical officer of the jail. The report of the latter was communicated by the Municipal Commissioner to the Bombay papers, and was reproduced by them, and I remember distinctly that it was identical with mine.

In the experimental note book which I have with me here, on page 696, the following details are given under date 5.11.97.

"(3.) Mahomed Hussein (not inoculated). Fever since yesterday, 4.11.97. Now unconscious, cannot answer questions."

"6.11.97. Still unconscious. No glands."

"7.11.97. Since yesterday evening painful and swollen gland in right femoral region."

"8.11.97. Mahomed Hussein died at 3.30 p.m."

On page 702 of the same note book, in a table made by Mr. Hall, Superintendent of the Jail, Mr. King and myself, in the office of the jail, under the date of 4.11.97, the space for inoculated shows a blank, that for the uninoculated shows one case fatal.

In another table referring to the attacks of plague in vaccinated against small-pox, and which I made out on the 8th February 1897, also with the assistance of the authorities of the jail, Mahomed Hussein, re-vaccinated on 4th March 1897, is shown also among the uninoculated; and at no moment, although the details of the outbreak were for many weeks examined and re-examined time after time, has it been mentioned that a fatal case of plague among the inoculated occurred after the first three fatal cases (those of the 30th January). It should be no difficulty whatever to find out from the jail authorities how it occurred now that the prisoner in question has been stated to be an inoculated.

(*h.*) Byculla House of Correction, 4th February; cases and deaths in inoculated: my figures, 0 and 0; "official figures," 1 and 1.

Vide above, paragraph (*g*).

(*i.*) February 6th, cases and deaths in uninoculated: my figures, 5 and 1; "official figures," 4 and 1.

My figures include prisoner Mummo Ibrahim, No. 993, who, although admitted to the plague shed on 7th February and shown in the "official figures" under that date, had fever already since the 6th.

(*j.*) Same date, cases and deaths in inoculated: my figures, 1 and 0; "official figures," 0 and 0.

My figures refer to prisoner Shamram Sittoram, No. 1,366, who, although admitted to the plague shed on 7th February, and shown in the "official figures" under that date, had fever already since the 6th.

(*k.*) The difference under the date of February 7th, is explained in the above paragraphs (*i.*) and (*j.*).

Summary of the Details referring to the Byculla Jail.

It will be seen from the above that the important differences between mine and the "official figures" consist in—

(1) Prisoner Mahomed Hussein being referred to in the "official figures" as an inoculated, which seems to me to be undoubtedly a mistake, and which can be verified by reference to the list of inoculated; and

(2) In the date under which prisoners Govinda Pandu, Keishoo Umar Shunkar, and Abdul Karim Gulam Hussein are referred to, and which in my table represents the date of the outset of the disease, while the "official figures" refer to the date of their admission to the plague shed and of entry in the Plague Hospital register.

The Umarkhadi Common Jail, Bombay.

(*a.*) Paragraph 1 of your Appendix: only 199 prisoners were inoculated, as the "official figures" rightly show. I do not remember having stated that 201 were inoculated. If I did, my mistake was probably due to the fact that the number of persons inoculated in the Umarkhadi jail on the 1st January 1898 was, indeed, 201, but two of them were Major Collie, I.M.S., the medical officer of the jail, and Mr. N. M. Wadiagaonkar; the latter, I believe, is the Assistant Surgeon on duty in the jail. But I believe it to be likely that I have not stated that 201 prisoners were inoculated; that that number was concluded, by the author of your appendix, from my stating that the total number of prisoners brought to the courtyard on the 1st January 1898 was 402, and that every second man or woman were inoculated. The author, taking the half of 402 as having been inoculated, did not consider that I have added that two of the prisoners who happened to be second in a pair, did not choose to be inoculated, which brought the number of 201 down to 199, and that of uninoculated to 203. In any case, it is certain, from the nominal list of the inoculated on that occasion, which I have here with me, that the number 199 is the correct one.

On the other hand, the number of uninoculated was by three higher than that mentioned in the "official figures" (203 instead of 200), and the total was 402, as I have stated. This is apparent from the nominal list, with all the particulars of the uninoculated prisoners present in the jail on the 1st January 1898, which list I have also with me here. The list shows in all 216 names, of whom six, viz.,—

Mahadu Kondaji	- -	Prisoner No. 7
Kassamkhan Amer Mahomed		,, No. 127
Kissan Hari	- -	,, No. 214
Hari Bahaji	- -	,, No. 257
Lenna Penna	- -	,, No. 306 and
Jiwee, wife of Peera	-	,, No. 42

were released the same morning while we were doing inoculation, five were on the sick list, suffering from various diseases, and kept under conditions different from those of the bulk of the prisoners, viz.:—

Kasmat Waman Lele, prisoner No. 205, suffering from curvature of spine since 26.11.97;

Kameedali Taigali, No. 183, down with an abscess since 17.11.97;

Lakmanji Mathabhai, No. 225, down with an abscess since 3.12.97;

Mahomed Walikhan, No. 83, suffering from chronic diarrhœa since 12.10.97; and

Koudia Siwa, No. 120, suffering from ague since 3.12.97;

and lastly, two were isolated in the plague ward, viz.:—

Moolabux Rahimbux, No. 151, attacked with plague on 31.12.97.; and

Arjuna Raji, No. 215, attacked on same date.

This leaves 203 uninoculated, who lived under the same conditions and remained exposed to the same chance of infection as the 199 inoculated.

(*b*) Paragraph 2 of your appendix, referring to the Umarkhadi Jail. In the list of 216 uninoculated prisoners who were present in the jail on the day of inoculation (including the plague patients who were still alive), the following 12 are shown to have been attacked with plague:—

Molabux Rahimbux, No. 151, attacked on 31.12.97, died on 1.1.98.

Arjuna Raju, No. 215, attacked 31.12.97, died 6.1.98.
Booda Hanma, No. 13, attacked 1.1.98, died 4.1.98.
Andrew Menuse, No. 278, attacked 2.1.98, recovered.
Ramjan Elahibux, No. 186, attacked 17.1.98, died 22.1.98.
Sadu Rama, No. 147, attacked 18.1.98, recovered.
Sheik Hussein Sheik Baban, No. 33, attacked 18.1.98, died 20.1.98.
Govind Rama, No. 65, attacked 20.1.98, recovered.
Bhori Sakaram, No. 163, attacked 20.1.98, recovered.
Karimkhan Azamkhan, No. 283, attacked 24.1.98, died 27.1.98.
Maruti Babaja, No. 35, attacked 24.1.98, died 26.1.98.
Girder Motiram, No. 104, attacked 30.1.98, died 3.11.98.

But there must have been a 13th fatal case of plague in the jail, not mentioned, among the 216 prisoners, as he was already dead on the 1st January 1898, when the inoculations were done. This results from the following: the above list of 12 patients begins with two cases of plague which occurred on the day before the inoculation, viz., on the 31st December 1897, and which were still alive at the time of inoculation. These were:—

Molabux Rahimbux, No. 151, attacked on 31.1.97, died on 1.1.98, and
Arjuna Raju, No. 215, attacked 31.12.97, died on 6.1.98.

On the 31st of December of 1897 I was in Poona, organizing with Lieut.-Colonel McConaghy, I.M.S., then Civil Surgeon there, two inoculation stations; and there must have occurred in the Umarkhadi Jail a fatal case a few days before the 31st December, as before leaving for Poona I had arranged with Dr. Leon, on plague duty in the Umarkhadi District of Bombay, that should another case occur in the jail he should wire the information to me to Poona, and I would come down to Bombay to inoculate the prisoners personally. It was on the occurrence of those two subsequent cases of the 31st of December that I received the wire from him, upon which I indeed returned to Bombay and inoculated the prisoners on the New Year's Day. Dr. Leon is in London, serving in the Paddington Infirmary, at Harrow Road, and I wired to him on the 6th instant asking for his notes on the plague cases at Umarkhadi; but, as will be seen from the attached reply, they could not be got immediately. I shall forward further details to the Commission if I get them.

The inoculations were done very early, about 6 or 7 a.m., on the 1st of January 1898, and it was because of this circumstance that I did not exclude from the list the case of Booda Hanma, No. 13, attacked in the course of that day. The "official figures," mentioning only the attacks in those who were still alive and present in the jail on the 1st January 1898, omit the case of the prisoner who died a few days before (including him possibly among the four non-inoculated prisoners attacked who were not in jail on 1st January 1898); on the other hand, I presume, they thought it safer to reckon the case which occurred on the 1st of January among those that took place before inoculation, although, as it appears from the numbers of 199 inoculated and 203 uninoculated, Booda Hanma must have been in the courtyard, in the ranks of prisoners paraded before us, while the inoculation was done.

The above completes the analysis of the discrepancies. I can only regret that those discrepancies did not come before us while in Bombay. It will be seen from the above explanations that they are of a nature easily to be substantiated by reference to the official books and by a few explanations from the officials as to details not recorded in the tabulated official books.

In case the Commission finds it desirable to have any further data as to the observations in the jails, or any others on which the evidence given by me bears, I shall hold myself in readiness to meet them, if invited, on the 12th instant.

I take this opportunity only of drawing their attention to a circumstance which may possibly render less paradoxical the table of mortality in Karachi among the inoculated and uninoculated Khoja children with regard to which I was questioned by the Commission in Bombay.

I did not know at the time that Dr. Kaka, the Health Officer of Karachi, who carried out the inoculations there, had not inoculated children in arms and under one year of age, on the ground that they do not take plague (which is, indeed, to a very great extent, the case). On referring to the vital statistics it will be seen that the normal mortality among children in India falls chiefly among those under one year; I believe it is often four, five, even six times higher than the mortality among children above one and up to five years; and when compared with the total mortality in a community that of children below one is by far the largest item. By leaving children below 1 in the group of the uninoculated, Dr. Kaka freed the inoculated from that largest item of the normal mortality. Considering further that the observations refer to a time subsequent to a very severe epidemic, which must have killed off a number of sickly individuals in the groups above one year; the absence of deaths amongst the inoculated from general causes during the six months under observation seems to me more comprehensible.

In giving the above considerations, I, of course, do not mean to take upon myself the responsibility for the Karachi observations, as I have never been in Karachi and am unacquainted with the conditions under which the observations were made. At the same time, in the inquiries made in Bombay, I could not detect the least reason for doubting the perfect good faith and veracity not only of the officers who carried out the observations but of the inoculated community itself amongst whom the observations were carried out.

Enclosure in No. III.

Paddington Infirmary,
Harrow Road, W.,
September 7th, 1899.

DEAR HAFFKINE,

I WENT to Portland Place to-day and looked for the notes of the plague cases, but I am sorry to say I could not find them. Our house is in the hands of the builders and everything is stowed away all over the place, so it is quite possible that they will turn up later on, when I will let you have them. Kind regards from,

Yours sincerely,
JOHN P. LEON.

IV.

On the 12th September 1899, the Commission informed Mr. Haffkine that they did not propose to request him to appear to put any oral statement before them, but that they were making inquiries by telegram from the Government of Bombay as to whether Mahomed Hussein, Prisoner No. 988, in the Byculla Jail, Bombay, was or was not inoculated in January 1897. The Commissioners also desired Mr. Haffkine to ascertain by telegram whether Mahomed Hussein appears in the records in his laboratory as inoculated or not. A telegram was accordingly sent by the Commission to the Government of Bombay through the Government of India, and Mr. Haffkine also telegraphed to his laboratory in Bombay asking that the required information might be sent by telegram through the India Office.

V.

The following telegram was received from the Government of India through the India Office on the the 20th September, 1899:—

"Your telegram, 12th September, Prisoner 988, Mahomed Hussein, Byculla Jail, was not inoculated."

KATNI - - Lime exported from Katni.

KAVIRAJ - - A Bengali native medical practitioner who follows the Hindu system of medicine.

KAYASTH - - The name of a caste of Hindus who are usually clerks and accountants.

KHALASI - - A native sailor.

KHALIFA - - The name of a caste.

KHALPA - - The name of a caste.

KHAN - - In Bombay, an inn.

KHARWA - - The name of a caste of fishermen and sailors.

KHATI - - The name of a caste.

KHATIK - - The name of a low caste of which the members support themselves principally by keeping pigs and poultry.

KHATRI - - The name of a caste of which the members are money-lenders, bankers, and traders; they also own land, though they do not, except very rarely, cultivate it themselves.

KHETRI - - *See* Khatri.

KHOJA - - An influential and well-to-do section of Muhammadans, who are merchants and traders; the majority follow the spiritual leadership of H.H. the Aga Khan of Bombay. In Karachi there are two sects, of which one, the Panjabhai sect, recognises the authority of the Aga Khan, and the other, the Pirai sect, does not recognise his authority.

KHUD (KHAD) - A hillside, a steep place, a declivity.

KHUDABADI - - The name of a caste.

KOLI - - The name of a low caste of which the members are generally fishermen or cultivators.

KOMATI - - The name of one of the principal cultivating castes in Madras.

KONI - - A kind of grain, a variety of panicum.

KONKANI - - A native of the Konkan, the districts south of Bombay, between the Ghats (*q.v.*) and the sea.

KOONBI - - *See* Kunbi.

KOS - - A measure of distance, generally about two miles.

KOTWAL - - A superior officer of police, an officer in charge of a police station; in the Central Provinces, a village official.

KULKARNI - - A village accountant.

KUMBH - - A great religious festival held every twelfth year at Hardwar in the North-Western Provinces.

KUMBHAR - - *See* Kumhar.

KUMHAR (*fem.* KUMHARIN). A potter; the name of a caste of which the members are generally potters.

KUNALI - - A drain, a pipe.

KUNBI - - The name of a cultivating caste widely distributed over Central India and other parts of India.

KURESHI - - A member of a class of Muhammadans who claim connexion with the tribe of Kuresh, of which the father of the Prophet Muhammad was chief.

KUTCHA - - *See* Kachcha.

LAC - - *See* Lakh.

LAKH - - One hundred thousand.

LAKHERI - - The name of a caste of which the members work in lac, and make and sell bangles.

LALA - - An honorific title among Hindus; the name of a caste.

LALARI - - *See* Lilari.

LAMBARDAR - The headman of a village, who is responsible for the collection of the Government revenue, and for assistance in the maintenance of order and the execution of Government orders.

LASCAR - - Originally, a camp follower; an employé, *e.g.*, in the Arsenal Establishment or in the Fire Brigade; a sailor.

LATHI - - A stick or club.

LEEPO - - To plaster with earth and cow-dung, the floors of most native houses being every week renewed in this way.

LEPO, LEPOED, LEPOING. *See* Leepo.

LILARI - - The name of a caste of which the members are cloth dyers.

LINGAET, LINGAIT, LINGAYAT. The name of a sect of Shivaite Hindus which wears the "linga" as a badge.

LODHA - - The name of a cultivating caste in Northern and Central India.

LOHANA - - The name of a caste of Hindus of Sind, who are traders, agriculturists, and Government servants.

LOHAR - - A blacksmith; the name of a caste of which the members are blacksmiths.

LONARI - - The name of a caste of charcoal burners and sellers.

LUVANA - - *See* Lohana.

MACHCHI (MACHI) - The name of a caste of which the members are generally fishermen and boatmen.

MADHUA - - *See* Mandua.

MADRASSEE - - A native of the Madras Presidency.

MAGH SANKRANT - The beginning of the Hindu month of Magh (January—February).

MAGH MELA - An important Hindu festival held in certain years near Allahabad in the month of Magh (January—February).

MAHAJAN - - A Hindu merchant or banker.

MAHAL - - A subdivision of a jurisdiction, area, or town; a ward or quarter of a town.

MAHALKARI - An officer, assistant to the Mamlatdar (*q.v.*), in charge of a mahal or subdivision of a taluka (*q.v.*).

MAHAMARI - - Literally "the great disease," a name applied to the plague endemic in Kumaun and Garhwal.

MAHANT (MAHUNT) - The head of a body of Hindu ascetics or of a Hindu religious establishment or mat (*q.v.*).

MAHAR - - The name of a low caste of villagers in the Deccan, who work as menial servants, scavengers, &c.

MAHARWAD, MAHARWARA. The quarter of a town or village occupied by Mahars.

MAHRATTA, MAHRATTI. A race or people divided roughly into two important classes, the Brahmans and the low castes, formerly the rulers of a large part of India, and now inhabiting the Konkan, Khandesh, the Berars, and the Deccan.

MAIDAN - - A plain, a piece of open ground.

MAKRANI - - A native of Makran, in Baluchistan, a class of Muhammadans.

MALA - - - A garden.

MALHI - - The name of a caste.

MALI - - - A gardener; the name of a caste of which the members are chiefly gardeners and agriculturists.

MAMLATDAR - A native officer with revenue and magisterial powers in charge, as assistant to the Collector, of a taluka or subdivision of a Collectorate.

MANDUA, MANDWA - A kind of grain (*Eleucine coracana*).

MANDWAH - - A light bamboo hut or shed with grass roof.

MANG - - - The name of a low caste of which the members are often weavers, scavengers, and menial servants.

MANGELA - - The name of a caste.

MANJHAND - - The name of a caste.

MARWARI - - A native of Marwar in Central India; a name often used to signify a banker, money-lender, or grain-dealer.

MASAN - - The name of a caste.

MASJID - - A mosque, a Muhammadan place of worship.

MASSAL, MASSALCHI A domestic servant.

MAT - - - A Hindu shrine, an establishment or monastery for Gosains or other Hindu ascetics.

MATADAR - - In the Baroda State, hereditary village officers who act as sub-Patels or assistants to the village headmen.

MEGHWAL, MEGHWAR The name of a low caste who work as weavers, coolies, and sweepers.

MEHROBIR - - The name of a caste.

MEHTAR, MEHTER - A sweeper or scavenger; the name of a caste of which the members are sweepers.

MEKRANI - - *See* Makrani.

MELA - - A Hindu religious fair or gathering.

MEMON - - The name of a caste of Muhammadans who engage extensively in trade.

MEMRIS - - The name of a caste.

MENGWAR - - *See* Meghwar.

MOCHI - - A shoemaker, the name of a caste of which the members are principally shoemakers and workers in leather.

MODH - - The name of a section of the Banniah caste.

MODI - - A shopkeeper, grocer, or grain-seller.

MOGA - - An opening, an outlet for a drain.

MOHALLA - - *See* Muhalla.

MOHANA - - The name of a caste.

MOHARRIR - - *See* Muharrir.

MOHURRUM (MUHARAM). The first month of the Muhammadan year, in which the Sunni sect of the Muhammadans celebrate a religious observance in commemoration of the death of Hussain, the son of Ali, the son-in-law of the Prophet Muhammad.

MOMIN - - The name of a caste.

MORI - - An opening, an outlet for a drain.

MUCCADUM - - The superintendent of a gang of workmen, a headman of coolies.

MUFASSIL (MOFASIL) The part of a Presidency or Province in India outside the Presidency, or capital, town.

MUGHAL - - A descendant of a native of Tartary, a class of Muhammadans.

MUHALLA - A ward or quarter of a town.

MUHARRIR - - A clerk or vernacular writer.

MUKHTYARKAR - In Sind, a revenue officer.

MULLA - - A Muhammadan priest.

MULO - - The name of a caste.

NAGAR BRAHMAN - The name of a section of the Brahman caste in the Bombay Presidency.

NAHNI - - A washing place, a lavatory.

NAI - - A barber.

NAIB-TAHSILDAR - Native officers who act as assistants or deputies to Tahsildars (*q.v.*).

NAIK - - - A subordinate officer, a corporal in the Army or Police.

NAIKINI - - A dancing girl.

NAKA - - - A guard, post, or picquet, at the junction of cross roads, fords, or other places where the movements of travellers can be checked.

NAKADAR - - A guard at a naka (*q.v.*).

NAND - - A large earthen vessel or pan.

NARWEKAR - - The name of a caste.

NASARPURI - The name of a caste.

NATRA - - The name of a caste of gypsies who live by begging and peddling things for household use such as iron tongs, spoons, &c.

NAWAB - - - An honorific title among Muhammadans; the ruler of a Muhammadan Native State.

NELA TUTIYA - Copper sulphate.

NIZAM - - The ruler of the Native State of Hyderabad, in the Deccan.

NULLAH - - A watercourse or stream.

NUMRIO - - The name of a caste.

OOPLIES - - Cakes of dried cowdung made for use as fuel.

OSWAL - - The name of a section of the Banniah caste.

OUTCASTE - - A member of a caste which does not abstain from acts considered impure—such, for instance, as dealing with night soil or handling dead bodies—and with whom the members of castes which do abstain from the acts considered impure do not associate in eating, drinking, or social intercourse.

PADAMSALI - The name of a caste.

PADHAN - - The headman of a village in Kumaun and Garhwal.

PADIAR - - The name of a caste.

PAGEE (PAJI) - An outcaste (*q.v.*).

PAGRI - - A headcloth or turban.

PAHARAWALA - A watchman, a guard.

PALKI - - A litter, a palankin.

PALWEGAR - - The name of a caste of silk workers.

PAN - - The leaf of the *piper betel*, chewed with the areca nut (supari) and other ingredients.

PANCH - - - A headman, an arbitrator, a man of influence in a village or community.

PANCHAYAT - A committee of panches (*q.v.*), by which local affairs are discussed and settled.

PANCHOLI - - The name of a caste.

PANDA - - The name of a section of the Brahman caste who have to do with death ceremonies, &c.

PANDAL - - A large tent or temporary shelter.

PANJABI - - A native of the Province of the Panjab.

PARAWALLA - - *See* Paharawala.

PARBHU - - The name of a section of the Brahman caste.

PARCHERRY - - In Madras, the outskirts of a town where the lower castes generally live.

PARDAH - - A curtain or screen, privacy; the seclusion of women.

PARDA-NASHIN - A woman who observes the practice of seclusion.

PARDESI - - Literally "a foreigner," a word used in Bombay to signify a person who comes from Upper India or from a place outside Bombay.

PARGANA - - A subdivision of a district or jurisdiction.

PARIAH - - An outcaste (*q.v.*).

PARSEE - - - A prosperous community of traders and professional men, descendants of the ancient Persians, who have retained the religion of Zoroaster, and have been settled chiefly in Bombay and towns on the Bombay coast for about 1800 years.

PARWARI - - The name of a caste.

PATEL - - - The headman of a village.

PATH - - The reading or reciting of the Hindu or Sikh religious books.

PATHAN - - - A native of the districts on the North-West of the Panjab and the country immediately beyond.

PATTAWALA - A chaprasi (*q.v.*).

PATTI - - - A division of the proprietary holding or of the proprietary body in a village.

PATTIDAR - - Literally "a sharer," a village landowner descended from one of the founders of the village; the name of a caste.

PATWARI - - A village accountant.

PEON - - A messenger or orderly, a chaprasi (*q.v.*).

PET, PETA, PETH, PETTAH. A market or bazar, a ward or quarter of a town.

PHAURA - - A hoe or mattock.

PHOOS - - Dried grass or stalks of corn.

PHUTKIA ROG - A name by which the plague endemic in Kumaun and Garhwal is known there.

PICE - - A coin of the Government of India currency, equal to three pies, or the 64th part of a rupee (*q.v.*).

PIE - - A coin of the Government of India currency, the 192nd part of a rupee (*q.v.*).

PIR - - - A venerable personage, a Muhammadan saint.

POKARNA - - The name of a section of the Brahman caste.

POLE - - The houses situated on each side of a narrow lane which has an opening at one end only.

POOS - - - A month of the Hindu calendar, December—January.

PORWAL - - The name of a section of the Banniah caste.

PUCCA, PUCKA - *See* Pukka.

PUJARI - - A priest in attendance at a Hindu temple or shrine.

PUGRI - - *See* Pagri.

PUKKA - - - Mature, firm, substantial, lasting; with reference to houses, a "pukka house" is one made of brick or stone and mortar in contradistinction to one made of mud or thatch, and in reference to floors, a "pukka floor" is a paved floor in contradistinction to a floor of earth, or of earth and cowdung.

PULA - - Long grass, used for thatching, making huts, &c.

PUNCHAYAT - - *See* Panchayat.

PUNDIT - - A learned man, a common title for Brahmans, the name of a section of the Brahman caste.

PUNKHA - - - A fan.

PURDAH - - *See* Pardah.

QASAI - - - A butcher; the name of a caste of which the members are butchers.

RAHBARI - - The name of a caste of which the members are generally owners of camels used for transport, &c.

RAJBHARA - - The name of a caste.

RAJA - - An honorific title; the ruler of a Native State.

RAJPUT - - - The name of the highest lay caste of the Hindus, the members of which claim descent from the ancient Hindu Kings of India.

RAMDASI - - A Sikh convert from the Chamar caste.

RAO - - - An honorific title among Hindus; the ruler of a Native State.

RAWAL - - The name of a caste.

RAWALIA - - The name of a caste.

RAWAT - - The name of a caste.

RAZAI - - - A quilt or coverlet usually stuffed with raw cotton.

REGUR (REGAR) - Black cotton soil.

RESAI - - *See* Razai.

RUPEE - - - The standard coin of the silver currency of the Government of India, equal to $\frac{1}{15}$ of a pound sterling.

RUS KAPOOR - A mixture of perchloride of mercury and calomel.

RYOT - - - A cultivator or agriculturist.

SADABART - - A Hindu perpetual endowment for a religious or charitable purpose, such as the daily distribution of food or alms to the poor or to travellers.

SADHU - - A Hindu mendicant who begs in the name of religion.

SADR - - The chief town in a district at which the headquarters of the civil administration are fixed.

SAGAR - - - The name of a caste.

SAHIB - - A gentleman, generally used to signify an Englishman.

SAHTO - - - The name of a caste.

SAHUKAR - - A Hindu banker, money-lender, or trader.

SAIS - - - A groom.

SALAT - - The name of a caste.

SALI - - - The name of a caste.

SANGAR - - The name of a caste of blanket sellers.

SANJAR - - The term used in Kumaun and Garhwal for an infectious fever, probably typhus.

SANKRANT - - The sun's entering into a new sign.

SANSI - - - The name of a low caste, of which the members lead a wandering life and subsist by begging and thieving.

SARAVAT - - The name of a caste.

SARI - - - A shawl or outer covering worn by women, a chaddar (*q.v.*).

SARKARI - - Official, governmental.

SARKARKUN - - A superior officer of the Salt or Customs Departments stationed at one of the smaller ports in the Bombay Presidency.

SARSWAT, SARSUD - The name of a section of the Brahman caste.

SATA - - - The name of a caste.

SAUJRANI - - The name of a caste.

SAWAR - - - A mounted man; a mounted policeman; a cavalry soldier.

SAYAD - - A class of Muhammadans who claim descent from the Prophet Muhammad through his son-in-law and successor Ali and his daughter Fatma.

SEER - - The name of the standard weight in India, about two pounds avoirdupois.

SEPOY - - A soldier, a constable or guard employed in the Police, Customs, or other Department.

SERAI - - - A rest house for travellers.

SETHI (SETH) - A Hindu merchant or banker.

SHAHTIR - - - A rafter.

SHASTRAS - - The sacred books or scriptures of the Hindus.

SHEIKH - - A title taken by Muhammadans who are descended from the Prophet Muhammad, and given to those who become converts to Muhammadanism.

SHENNI - - The name of a caste of fish-eating Brahmans.

SHIAH - - - The name of the sect of Muhammadans which does not acknowledge the authority of the traditions attached to the Quran, or of Abubakr, Umar, and Usman, the immediate successors of the Prophet Muhammad, and regards Ali as the second Khalif.

SHIDI - - The name of a caste.

SHIKARI - - A hunter, a sportsman.

SHIMPI - - - The name of a tailor caste.

SHRAFF - - A money changer, banker, or money-lender.

SHRAWAK - - - A lay votary of a Buddha or Jaina.

SIKH - - The name of the principal class of the people of the Panjab, who are distinguished by their religion as followers of the teachings of the Guru Nanak.

SIRKHI - - Reed grass, principally used for mat making.

SIR-SUBA - - A high revenue officer in charge of a division of a Native State.

SONAR - - *See* Sunar.

SONI - - - *See* Sunar.

SOWAR - - *See* Sawar.

SUB-PATEL - - *See* Matadar.

SUBA - - A division or jurisdiction in a Native State, the officer in charge of a Suba.

SUDR - - - *See* Sadr.

SUMMA - - The name of a caste.

SUNAR - - A goldsmith; the name of a caste of which the members are generally goldsmiths.

SUNNI - - The name of the orthodox sect of the Muhammadans which recognises the authority of Abubakr, Umar, Usman, and Ali, the four immediate successors of the Prophet Muhammad, and accepts the authority of certain traditions attached to the Quran.

SURTI - - - A native of Surat in Bombay, a caste of people from Surat who go out to Bombay and other places for service as grooms, cooks, butlers, &c.

SUTAR - - The name of a caste.

SYCE - - - *See* Sais.

TAHSIL - - An administrative subdivision of a district or Collectorate (*q.v.*).

TAHSILDAR - - A native officer with revenue and magisterial powers in charge, as assistant to the Collector, of a Tahsil.

TAI - - - The name of a caste of which the members are generally weavers.

TAIWAD - - - The quarter of a town occupied by Tais.

TAKIA - - A Muhammadan shrine, the abode of a Muhammadan fakir.

TANAI - - - The name of a caste.

TALATI - - A village accountant.

TALAVIA - - The name of a caste.

TALUKA - - An administrative subdivision of a District or Collectorate (*q.v.*).

TALUKDAR - - In the Hyderabad State, an officer corresponding to the Collector (*q.v.*) in British India, in charge of a jurisdiction corresponding to a Collectorate.

TAMBOLI - - The keeper of a shop for the sale of tobacco, pan (*q. v.*), and betel nut.

TAPODAN - - The name of a caste.

TARKHAN - - A carpenter; the name of a caste of which the members are carpenters.

TATTI HUTS - - Huts of reed and grass.

TELI - - An oil presser and seller; the name of a caste of which the members are generally oilmen.

THAKUR - - A title of respect among Hindus; the name of a caste.

THANA - - A police station.

THANADAR - - A superior police officer in charge of a police station.

THATHARI - - A brassworker; the name of a caste of which the members are generally brassworkers.

THOKDAR - - A leader or man of influence in a village or caste.

TICCA - - A term used to signify vaccination or inoculation.

TICCA GHARRI (THEKA GARI). A wheeled conveyance licensed for hire, a cab.

TICCA WALLAH - The driver of a conveyance for hire, a cabman.

TILAT - - A Chief of the Rajput clan of the Jadejas in the Cutch State.

Tola	A measure of weight, $\frac{1}{80}$ of a seer (*q.v.*), equal to about 180 grains troy.
Tomtom	A native drum.
Topeewallah (Topiwala).	A hatter; a person who wears a hat, a European.
Toti	The name of a caste.
Turia	The name of a caste of which the members are generally weavers.
Vaghri	*See* Waghri.
Vahivatdar	In the Baroda State, an officer in charge of a local jurisdiction.
Vaid, Vaidia, Vaidu.	*See* Baid.
Vakil	An agent, and especially a legal agent, a pleader.
Valund	The name of a caste.
Vanho	The name of a caste.
Vanja	The name of a caste.
Veragi	*See* Bairagi.
Waddar	The name of a wandering caste of stone cutters and rat catchers.
Wadho	The name of a caste.
Wadi	A garden, a house or group of houses in a garden.
Waghila	The name of a clan of Rajputs in the Cutch State.
Waghri	The name of a low caste of which the members earn their living by snaring and selling game, by basket weaving, and by acting as shikaris (*q.v.*) and labourers.
Wahivatdar	*See* Vahivatdar.
Walki	The name of a caste.
Wanan	The name of a caste.
Wani	*See* Banniah.
Wari	*See* Wadi.
Yogi	A Hindu ascetic or mendicant.
Zaildar	An influential landowner appointed for a zail, or subdivision of a Collectorate, to assist in the suppression of crime and in the execution of the orders of Government.
Zanana, Zenana	The quarter of a house in which the women live in seclusion.
Zamindar	A landowner, an agriculturist.
Zulm	Tyranny, oppression.

INDEX

OF THE

EVIDENCE OF WITNESSES

AND OF THE

APPENDICES.

ACCIDENTAL INOCULATION OF PLAGUE VIRUS; CASES RESULTING FROM:

No local signs of inflammation observed in case of accidental inoculation, 9625.

See Incubation period; *Incubation Period in cases of Plague contracted from direct Inoculation.*

ACCLIMATISATION OF PLAGUE BACILLUS TO ENVIRONMENT INTO WHICH INTRODUCED; NECESSITY FOR:

Theory of acclimatisation put forward to account for slow spread of plague, 18,998–19,005, 23,243, 23,318–29, 24,110.

Facts bearing on the acclimatisation theory, 26,537.

ACETIC ACID:

Results of experiments, II. 7.

ACHARJ, CASES AMONG:

Acharj, low caste Brahmans, entitled to receive dead men's clothes, not specially attacked in Panjab, 10,321.

Acharj receive clothes of the dead and get plague at Kankhal, 9271.

At Kankhal: First cases among the Acharj, 9458.

Burning of funeral clothes stopped the plague among the Acharj in Kankhal, 9460.

In Jawalapur, special arrangements made and clothes of patients burned; Acharj got no plague, 9271.

ACID:

Acid reaction in articles of food kills the plague microbe in a very short time, 8544, II. 7 b.

Acidity developed in the bodies of persons dead of plague may aid in causing the disappearance of the microbe after death, II. 7; 8655, 8681–4.

Disinfectants in acidified solution should be used in combating plague, 8551.

One of the most important ingredients of the disinfecting fluid for mud floors, 17,292.

See Acetic Acid.
,, Carbolic Acid.
,, Formic Acid.
,, Hydrochloric Acid.
,, Laboratory experiments: fallacies of.

,, Nitric Acid.
,, Sulphuric Acid.

ADOPTION OF INOCULATION AS A GENERAL PLAGUE MEASURE:

See Inoculation with Haffkine's plague prophylactic.

AFTER EFFECTS OF INOCULATION WITH HAFFKINE'S FLUID:

See Inoculation with Haffkine's plague prophylactic.

AGE:

Age does not influence case mortality of plague.

Karachi: Table in three age-groups of total gross mortality for a period of three months before the appearance of plague, II. 150.

No apparent relation between age and liability to plague, 9587.

Old women nursing plague cases generally escape infection, 7407.

Old age confers some immunity, 7534.

AGE—*cont.*

Plague and Age:

Ankleshwar: Table of plague cases in regard to age, II. 244*a*.

Banga: Table showing the age of all persons attacked with plague, II. 94*a*.

Baroda: Table of mortality according to age. II. 287.

Bombay, Arthur Road Hospital: Plague patients by age, III. 459.

Bombay, Parel Hospital: Incidence of cases by sex, age, and religion, 7221.

Bombay: Incidence of plague and age, I. 392.

Bombay: Approximate ages of plague patients admitted to hospital, I. 378.

Calcutta; Incidence of plague by age, I. 474.

Daman: Ages of 625 people fatally attacked, 16,511.

Jullundur: Table showing per-centage of plague cases according to age during 1897, II. 103.

Karachi Plague Hospital: Statement of admission and mortality according to age, II. 173; II. 176.

Kotri: Table of cases according to age and sex, II. 185*a*.

Palanpur: Plague cases tabulated by age, II. 200.

Porbandar: plague cases tabulated by ages, II. 484.

Umreth: Table of total attacks and deaths by castes, sex, and age, II. 233.

See Children.
,, Inoculation with Haffkine's prophylactic, *age and inoculation* and *bars to inoculation.*

AGGLOMERATION OF BACILLI OF PLAGUE.

See Widal's test.

AIR.

See Air and Light.
,, Wind.

AIR AND LIGHT:

Bacillus of Plague, Survival in:

Dies in a few hours when exposed to air and light, I. 447.

Dies very soon in the open air in articles taken from infected districts, 9296, 9297.

Grows when covered up from the light in laboratory experiments, 25,304.

Microbe establishes itself most in darkness, 9683.

Efficacy as disinfectant:

Experience at Kankhal and Jawalapur seems to show that infective material in clothes is soon destroyed by action of light and air, 9294–7.

Exposure of infected area to air, the most beneficial measure of disinfection, 13,643, 17,646.

Salaya, the benefits of disinfection by aeration shown in, 13,474.

Two months exposure to air and light necessary to make a dwelling innocuous, 11,493.

Influence on spread of plague:

Fresh air, sweetness, and light, chief enemies of plague, 12,018.

Light and air inimical to, and dark and badly ventilated places conducive of, the spread of plague, 10,377.

AIR AND LIGHT—*cont.*

Light and air of no importance with regard to plague, 18,481.
Open air and cleanliness the best preventives against plague, 17,711.
People who slept in the open air, even in filthy surroundings, escaped plague, 19,515.
Poona: Infection for a time raged very high in houses on raised platforms with plenty of air and light, 21,583.

See Housing.
,, Occupations.
,, Sanitary Conditions.
,, Ventilation.
,, Wind.

ALCOHOL:

Immunity from plague of heavy drinkers, III. 43.

ALIMENTARY CANAL:

Post-mortem appearances of alimentary canal, I. 367.

See Infection, modes of.
,, Food.
,, Stomach.

ANIMALS.

ANTS:

Ants found to be infected in one or two instances, 8530.
Ants, influence in spreading disease considered unimportant, I. 378.
Ants may have an influence in spreading plague, 8704, 8653.
Bacillus not found in supposed infected ants, 635.
No evidence that ants are infectious, 28,640.

ATTACKS OF PLAGUE; EFFECT OF INOCULATION ON:

See Inoculation with Haffkine's plague prophylactic.

ATTITUDE OF PEOPLE TOWARDS INOCULATION:

See Inoculation with Haffkine's plague prophylactic.

ATYPICAL FORM OF PLAGUE:

Abdominal form, result of infection through the gastro-intestinal canal, 20,388.
Abdominal or typhoid form very rare, 22,335.
Atypical cases those that had neither bubo nor pneumonia, 14,117.
Cerebral variety in which the temperature is never reduced, 18,533-7.
Primary laryngeal plague rather a case of cervical buboes pressing on the larynx, 20,812.

BACILLUS OF PLAGUE:

See Bacteriological characteristics of bacillus of plague.
,, Isolation of bacillus of plague.

BACTERIAL SEDIMENT IN HAFFKINE'S PLAGUE PROPHYLACTIC

See Haffkine's plague prophylactic, *constituents of.*

BACTERIOLOGICAL CHARACTERISTICS OF BACILLUS OF PLAGUE:

Aerobic species cannot live far under the surface of floors, 10,040.
Capsule: Bacillus of plague not found with, 5791.
Found singly, in pairs, and in chains, I. 441.
Growth: Grows slowly compared with other microbes, but can be recovered by cultivation if present in sufficient numbers to be visible under microscope, 1518, 1520.
Growth: Other micro-organisms in substances containing plague bacilli grow so much more rapidly that they crowd out the plague bacilli and render their recovery from such substances impossible, 26,341, 26,391.
Growth: Plague bacillus grows in an atmosphere of carbonic acid gas, 18,893.
Growth: Plague bacillus grows in an atmosphere of hydrogen, 18,893.
Growth: Plague bacillus seems to be at antagonism with bacterium coli, 1531.
Growth: Tests on the effect of bacillus coli on the growth of the plague bacillus proved it to have very little power, 20,150.
Growth: The stimulation of the activity of plagocytes can prevent the infection of plague in rats, 8524–5, 8586.
Motility: Difference of opinion regarding, 5790.
Motility: Feeble, noticed in hanging drop preparations, 5598.
Motility: Plague bacillus, being non-motile, cannot spread through the floor, 8575.
Penetrates to a certain depth into floors by growth, 11,457.
Points of difference between the plague bacillus of Kitasato and Yersin, 26,962.

See Cultures of bacillus of plague.
,, Inoculation of plague virus.
,, Involution forms of bacillus of plague.
,, Microscopic appearance of bacillus of plague
,, Period for which the plague bacillus can survive.
,, Staining characteristics of bacillus of plague.

,, Virulence of bacillus of plague.
,, Widal's test.

BACTERIOLOGICAL LABORATORIES AND IMPORTANCE OF BACTERIOLOGICAL EXAMINATION:

Necessity for:
Bacteriological examination the only means of certifying plague cases, 22,351.

Provision for:
Arrangements regarding bacteriological laboratories in India, 7900.
Bombay City: Bacteriological work carried on in M. Haffkine's and Municipal laboratories, 23, 615, 8488, 17,184, 17,315, 17,378, 17,450, 18,800, 26,185, &c.
Bombay City: Laboratory in Jamsetjee Hospital, 17,182.
Bombay Presidency: No experimental Government laboratory in the, 17,183.
Calcutta: Bacteriological work carried out in, 7470, 8391, 8501, I. 465, III. 655, &c.
Calcutta: No means of making bacteriological examinations, 8210.
Hyderabad State: Bacteriological work done in, 5160, &c.
India: Arrangements for bacteriological laboratories, 7900.
N.W.P.: Agra district, in, no convenience for making bacteriological examinations, 10,354.
N.W.P.: Appointment of Government bacteriologist, 8506, 8987.
Mysore: Government bacteriologist at Bangalore, 3537.
Punjab: Government makes no provision for bacteriological or microscopical examination in the Punjab, 10,610.

BAGS:

Hardwar: Plague supposed to be introduced by bags containing dead men's bones sent through the post, 9458.

See Gunny bags.

BANDICOOTS:
Died of plague, 3596.

BANGALORE:
Inoculations with Haffkine's prophylactic at:
City: Inoculations on a large scale pushed by the Mysore Government, 3261, 3482.
City: Statistics of inoculations in, 25,034.
City: Great numbers of inoculated as well as uninoculated left, 3521, 25,111.
City: Identification of the dead thrown into the streets difficult, 3522.
City: Concealment of cases took place even among the inoculated, 3287.
City: History of inoculation at the Wesleyan Mission, 3539-40.
City: History of inoculations at the Woollen Mills, 3482.
City: History of inoculations at French Rocks, results favourable, 3482, 3531.
Civil and Military Station: Remarks on the accuracy of the inoculation statistics relating to the troops, III. 287.
Civil and Military Station: Statistics of the number of inoculations performed, 25,034.
Civil and Military Station: Statistics of mortality among the inoculated very hard to get, 3105.
Civil and Military Station: Statistics of certified plague cases classified according to inoculation, 25,037.
Civil and Military Station: Statistics and evidence regarding the outbreak of plague among the troops, and the effects of inoculation among them, I. 114-5, I. 165-75, III. 281-7.

Introduction of plague into:
City and Civil and Military Station practically one place, and plague measures in both on similar lines, 2534-6.
City and Civil and Military Station: Precautionary measures adopted, 2606, 3219, 3442.
City: Gowdenpet quarter first found on 14th August 1898 to be infected, 3230, 3349, 3448-53.
City: Introduction of plague possibly by infected goods, raw hides, or rats, or on wagons coming by rail from Hubli, 3222-3.
City: Second separate focus of infection found in the Arlepet quarter, on the 22nd of August 1898, 3223-5.
City: Uncertainty as to the first case in the Arlepet quarter, and as to the source of infection, 3223, 3474-7.
Civil and Military Station: Case imported from Hubli by rail on 12th August 1898, 2538, 2545.
Civil and Military Station: Disease spread into, from the City, whence plague patients came over, 2547.

Statistics of plague at:
Bangalore and neighbourhood: Number of cases, 3481.
Bangalore and neighbourhood: Spread of plague in the villages, I. 131.
City: Mortality in, 3481.
City: Progress of plague, I. 129.
City: Statistics relating to the epidemic, 3479.
City and Civil and Military Station: Statistics relating to the epidemic, III. 274-5.
Civil and Military Station: Statistics of population and of plague attacks and deaths, I. 107-9.
Civil and Military Station: Mortality very high, 2611-4.

See Maps and Charts.

BANNIAHS AND TRADERS:
First cases among:
Baroda City: Plague first appeared in grain market, 15,459.
Bombay City: First detected case Banniah's wife, 592.
Bombay City: First outbreak in grain quarters among Banniahs, Jains, Bhatias, and Brahmans, 911.
Bulsar: First epidemic in grain sellers' street, which escaped in second epidemic, 16,316.

BANNIAHS AND TRADERS—*cont.*
Calcutta: First case detected in 1898, that of a shopkeeper, 6462.
Karachi: First outbreak began in street occupied by merchants trading with Bombay, 11,096.
Karachi: Second outbreak began among males of Banniah families who went on business to their shops, 11,197, 11,359.
Kotri: First case a Banniah, but probably not infected from his shop, 12,596, 12,706-8.
Nasik: Disease first noticed chiefly among grain sellers, 13,578, 14,693.
Sirohi: First 26 cases all Banniahs, 9764.

Granaries and shops, liability to contract plague in:
Bangalore: Cases traced to a shop, 3365-74.
Bombay City: First cases in granaries, 17,012.
Bombay City: Grain and flour sellers died in Bombay in 1896-7 in infected localities, but did not form centres for the spread of the disease, I. 378.
Bombay City: Not only epidemics, but also sporadic outbreaks, spread from granaries, 1000.
Chipagiri: Cases traced to a shop, 4945-50.
Infection caught in a granary, but not from the grain, 13,813.
Karachi City: Plague spread from granaries whence goods distributed by traders, and first appeared among those who went to their shops on business, 11,197, 11,359, 11,413.
Molagavelli: Cases traced to a shop, 4906.
Theory that in addition to rats and clothing, something indefinite in grain shops spreads plague, 11,278, 11,430.

Plague introduced by, into:
Asu, 12,449, 12,451.
Ilkal, 19512.
Jalgaon, 24,529.
Kaira villages, 14,053.
Kajurgi, 5501.
Molagavelli, 4980.
Palanpur, first outbreak, 13,054.
Palanpur, second outbreak, 13,059.
Poona, third outbreak, 25,860.
Reri, 12,446,-7, 12,486.
Sirohi, 6414, 9702.

Plague most severe among, in:
Ankleshwar, 14,448.
Baroda: Banniahs and low caste people considered most liable, 12,483.
Bombay City, 17,681-4.
Gadag, in December 1898, 23,608.
Hyderabad State: Banniahs (said to be low caste people) and Lingayats considered most liable, 5474-5.
Karachi, 11,118, 11,339, 11,357, 11,538.
Kotri, 12,578, 12,597, 12,640.

Spread of plague by:
Banniahs and traders travel more than others, being better able to do so, and come more in contact with people, hence human intercourse most important factor in, 10,244, 13,422, 23,607.
Grain stores not the cause of plague. None of the coolies attacked who cleared out an infected godown, 19,437.
Hubli: Plague not specially marked among traders, 1717.
Nasik: Banniahs and other parties from Bombay grain quarters continually found arriving ill with plague before local outbreak in Nasik, 13,758.
Nasik: Plague spread in villages by class of people corresponding to grocers, 14,693.
Pali, outbreak of 1836, spread of plague by traders in, remarkable; similar thing noticed now, 8705-7.
Rats as well as personal communication an important factor in, 3785-90, 3831-6, 15,459, 15,471, 17,837, 22,645-6.
Spread by Banniahs through grain and rats, 11,430.

See Evacuation: *attitude of the people towards evacuation.*
,, Habits of the people affecting liability to plague.

BEDS:
Cases most numerous in people sleeping on the floor, 24,349–51.
Christians in the village of Vadala sleeping in beds more immune than the Hindus sleeping on the floor, 19,446.
Europeans relatively immune because they sleep in beds, 19,447.
Karachi: In one house everyone got plague except one man, who slept on the only bed, 22,655.
Kumaun: People sleep on the floor, 26,625–6.
Most people in Poona sleep on the floor, 21,594.
Parts of the floor on which people sleep kept clean, 5903.
Sleeping on beds a greater protection than sleeping on floors, 22,555.
Sleeping on the floor a means of infection, 21,311, 21,498, 21,594, 24,319.

BHANG:
Immunity of persons who indulge in bhang from attacks of plague, III. 43.

BHATIAS:
Bombay: Suffer severely from plague in Mandvi ward, 911.
High plague mortality among the Bhatias in Bombay, 17,683.

BHILS:
Ankleshwar: Bhils least affected at, 14,445.
Bhils suffered less on account of their leading an open-air life and their residing on the outskirts of the town, II. 246.

BIRDS:
Immunity:
Birds not usually affected by plague, 908.
Birds unaffected by plague, I. 378.
Pigeons unaffected by large quantities of plague injected under the skin, 26,315.
Vultures immune against plague, 8644.
Plague Cases:
Fowls died with buboes in neck and groin in houses where, shortly before, plague had occurred, 19,096.

BLACK COTTON SOIL:
See Evacuation. *The rains and their effect on evacuation.*
,, Geological conditions.

BLOOD:
Character and life of bacillus in:
Bacillus of plague dies more slowly when obtained from the urine than from the blood, 26,337.
Bacilli from blood stain better than bacilli from cultures, 26,125.
In the blood and tissues of animals the character of the microbe is constant and distinctive, 26,123.
Discovery of bacillus in blood:
——: *Death, after:*
Always found after death in the blood, 1430-1.
Found abundant in the veins one hour after death, 26,401.
Found post-mortem in the blood, I. 370.
——: *Dejecta of patients:*
No plague microbes found in the bloody dejecta of human patients, 8603.
——: *Life in:*
Blood of living animals in the early stages of the disease, not found in the, 27,397.
Found in the blood of bubonic cases 24 hours before death, 10,443-4.
Found in blood during life, 1430-1, 7189.
Fifty-one hours before death the longest period in which found in the blood, 26,400.
Frequently obtained from blood of plague patient, 26,399.
Isolated in the living patient, about three hours before death, from the blood stream, 7189.
Not found in blood of plague patients, 1415.
Only found in blood just before death, I. 374, 4333.
Prognosis: Disappearance of bacillus from, sign of favourable prognosis, 20,807.

BLOOD—*cont.*
Prognosis: Presence of bacilli in the blood a bad prognosis, 20,805.
Prognosis: Recovery never noted when the blood was infected with the microbe, 17,402.
——: *Nose, Discharge from:*
Found in the bloody discharge from the nose in patient with sub-mental buboes, 26,259.
——: *Pneumonic Cases:*
Always to be found in the blood of patients who died of the pneumonic form, 17,258.
Post-mortem appearance:
Blood less coagulated than in death from other causes, 1425.
Of circulatory system, I. 368.
See Rats: *Discovery of bacillus in blood of.*

BOILING:
Adopted as a means of disinfection:
Articles boiled at Hardwar, 9047.
Bedding and clothing boiled in the Hyderabad State, 5155.
Clothes and bedding in Hyderabad State boiled twice, 5466.
Clothes and bedding boiled for a full hour, 1319, 5926, 18,124.
Clothing disinfected at Ankleshwar by placing it in carbolic acid lotion for half an hour, or simply boiling it in water, 14,255–7.
Clothing disinfected in Cutch Mandvi by boiling, II. 474.
Clothing disinfected by boiling on railways, 1315, 1319.
Grain bags disinfected at Hinganghat by boiling, 6066.

BOMBAY:
Inoculation with Haffkine's prophylactic in:
Details of the first 8,142 inoculations in the City, 32, 48-9, 52.
Every facility offered to the people in, 22,296–8.
Good effects of inoculation in 600 families of Parsees, 18,344-61.
Inoculation of the Cama Hospital nurses, 23,531.
Inoculation of nurses at the Jamsetjee Jeejeebhoy Hospital, 20,529–30
Observations in the cases of 2,000 Parsees inoculated with good result, 19,261–325.
Used and encouraged in, 918, 17,878.
See Byculla Jail.
,, Umarkhadi Common Jail.
Introduction of plague into:
Earliest cases: Case seen on 16th July 1896, 18,295.
Earliest cases: Cases seen in July 1896, 19,133.
Earliest cases: Cases occurred in July or August 1896, 1175.
Earliest cases: Cases seen in the middle of August 1896, 17,760.
Earliest cases: 13 cases seen on 11th September 1896, 20,412.
Earliest cases: Reported by Dr. Viegas on 23rd September 1896, 578–614, 1018.
Earliest cases: Appeared among the Banniahs, Jains, Bhatias, and Brahmans of the Mandvi quarter, 911.
Earliest cases: In Mandvi quarter and not in neighbourhood of places where Kumaun pilgrims stay, 1021–4.
Hong Kong: Bombay infected not from Kumaun, but from Hong Kong, whence infection imported in Chinese crackers, 19,016.
Hong Kong: Case of plague arrived at Bombay in March 1899 on board the *Bormida* from Hong Kong, 25,506.
Hong Kong: Importation from, 18,295.
Hong Kong: Imported from in Chinese crackers, and by dead rats, 17,772.
Hong Kong: No plague in ships arriving from, in 1897–98, 776.
Hong Kong: Probable source of infection, not Kumaun, whence a person coming to Bombay without breaking his journey would take about 12 days on the road, 26,691–704.
Hong Kong: Rats from Hong Kong imported the disease which did not come to Bombay from Kumaun, 22,247–53.

BOMBAY—*cont.*

Hong Kong: Rats, plague imported by sick rats from, 19,437.
Indigenous: Impression that plague indigenous in Bombay and neighbourhood, 901.
Indigenous: Plague indigenous in Bombay and not imported in 1896, 19,133.
Indigenous: Plague was not imported in 1896, but is indigenous in Bombay; cases occurred in 1893, 18,276.
Kumaun: Case resembling plague occurred among people from Kumaun who went to Burdwan in Bengal before outbreak in Bombay, 1158.
Kumaun: Importation from, improbable, 6186.
Kumaun: Plague imported into Bombay from, 1545.
Kumaun: Rats, imported in articles from Kumaun infected by diseased, 977, 988.
Kumaun: Three suspicious deaths occurred among pilgrims in August 1896, 1027.
Manner of Introduction: Report of Bombay Plague Research Committee regarding, I. 377.
Rats: Before plague broke out the rat population had enormously increased, and dogs that killed rats in Mandvi became ill, 997.
Sea: Importation by sea and not from Kumaun, 17,358.
Sea: Rats; no dead rats in ships coming to Bombay in 1896, 1191.

Statistics of mortality and general statement of measures in:

Measures adopted on first appearance of plague, 908–16.
Measures adopted on resumption of control of plague operations by municipal authorities in June 1898, I. 56–58 (1342–68); III. 305–10 (25,507–661).
Mortality: Average before outbreak of plague, fluctuating, 882–7.
Mortality in Bombay just before plague outbreak, and special meteorological conditions which prevailed, 892.
Mortality: Normal about 28 per mille, 25,722.
Mortality: Normal monthly from September 1896 to March 1899, 25,720.
Mortality: Recorded plague, from September 1896 to March 1899, 25,721.
Mortality: Total monthly, from September 1896 to March 1899, 25,719.
Statement of deaths and births from commencement of plague to May 1897, I. 394.
Statement showing the number of deaths from bubonic plague from September 1st, 1896, to March 16th, 1899, III. 310.
Statement showing the number of plague deaths from 1896–9, III. 313.
Table of total mortality per month from September 23rd, 1896, to the end of February 1899, III. 312.

See Maps and Charts.

BOOTS:

Boots and clean hands prevented disinfecting staff from taking infection, 16,007.
Chinese in Calcutta wear boots; only one case among them, 6863.
Europeans relatively immune because they wear boots, 19,447.
Infection through skin of feet probable as disease disappears from establishments employed in an infected place on employés getting boots, 7181.

See Habits of the people affecting liability to plague.

BORAHS:

Borahs at Surat kept themselves from intercourse with people of infected quarters, and escaped altogether, 16,071–2.
Borahs and upper classes least liable to infection, 22,673.
Borah community in Mandvi promptly segregated; low rate of mortality; treated with Yersin's serum, I. 353.
Borahs went into segregation camps in Mandvi and suffered little, although under no control, 473; 566.

BUBOES:

See Glands.
,, Glandular fever.

BUBONIC PLAGUE:

Character of:

Account of plague by the President of the Bombay Plague Research Committee, I. 377–97.
Anand Hospital: Among the 78 cases 54 were bubonic, 14 pneumonic, 4 bubonic and pneumonic, 5 atypical, and 8 septicæmic, 14,116.
Bubonic cases represent about 75 per cent. of the whole number of cases, 9389.
Bubonic type shades into septicæmic, I. 471.
Calcutta, classification of cases at Medical College Hospital, 7073.
Character of plague cases at Medical College Hospital, 6861.
Difference between septicæmic and bubonic plague the lesser resistance of the glands, I. 368.

Bubonic cases and pneumonia:

Pneumonia developed in bubonic cases, 14,121.

Bubonic as well as Pneumonic Plague contracted from Pneumonic cases:

Bubonic plague from pneumonic cases, 2 instances, 16,048.
Bubonic plague communicated by inoculation from pneumonic case, 7218.
Bubonic case contracted from bite of pnemonic patient, 4567.
Bubonic case contracted by medical attendance on pneumonic case, 9566.
In Gangaur from one case of probable pneumonic plague 37 deaths followed, both bubonic and pneumonic, 13 of the deaths being among the relatives of the first case, 15,182–5.
In one instance a pneumonic case gave rise to both bubonic and pneumonic cases among 8 persons, who all died, 17,990–1.
No instances of bubonic cases from infection by cases of pneumonic plague or *vice versâ*. 14,123, 14,709, 17,785, 17,890, 18,206–7, 18,440, 19,075–6.
No case of bubonic plague traced to contact with a pneumonic case, 12,729.
One case of pneumonic plague at Manora gave rise to one bubonic and 3 pneumonic cases, 12,997–8.
Pneumonic plague communicates the bubonic form as well as the pneumonic, 1517.
Pneumonic case gave rise to a bubonic case, 13,177.
Pneumonic plague, in one instance, gave rise to 2 bubonic cases, 18,214–6.
Six instances in which pneumonic cases gave rise to bubonic cases, 15,280.

Bubonic Cases give origin to Pneumonic Plague:

Bubonic case in one instance gave rise to combined bubonic and pneumonic case, 17,988–9.
Instance of infection of members of a family in Hardwar, one bubonic case followed by three bubonic and two pneumonic cases, 9558–60.
Mixed bubonic and pneumonic case gave rise to two pneumonic cases, 13,179–82.
No instances of pneumonic plague from bubonic case or *vice versâ*, 14,123, 14,709, 17,785–7, 17,890, 18,206–7, 18,440, 19,075–6.
No instance in which bubonic plague gave rise to pneumonic case, 19,208.
Pneumonic plague got by contact with bubonic cases, 12,728.
Pneumonic plague contracted from bubonic case, one instance, 16,048.
Six instances in which bubonic cases gave rise to pneumonic cases, 15,280.

Bubonic Cases give rise to Septicæmic Plague:

Bubonic plague case gave rise to a case of septicæmic plague with secondary pneumonia, 13,003–13.
Septicæmic plague contracted from bubonic; 10 instances, 16,048.
Septicæmic shades into bubonic form, I. 471.

Bubonic Cases infected from Bubonic Cases:

Bubonic plague, infection communicated from cases of bubonic plague in Reri, 12,482–6,

BUBONIC PLAGUE—*cont.*

Bubonic plague contracted from a bubonic case, one instance, 16,048.
Bubonic cases give rise to bubonic cases, the virus being carried by the hands to the mouth and nose, 17,985–7.
Bubonic plague not so infectious as pneumonic plague, but in one house 8 or 10 cases all bubonic infected from bubonic cases, 19,209–16,19,221–2.
In Rahon 16 cases and 10 deaths, all bubonic, without occurrence of any pneumonic cases, 10,596–9.
Two cases of bubonic plague probably contracted from bubonic cases in Dharwar Hospital, 1900–1.

Infectiousness of Bubonic Plague:
Bubonic plague infectious, but no instance noted of direct infection from bubonic case, 504–8.
Bubonic plague can spread disease only by the evacuations, 4372–3.
Bubonic plague not very infectious, 19,964.
Case of bubonic plague may become very infectious if pneumonia sets in, 6918.
In good sanitary surroundings, *e.g.*, hospitals, bubonic plague not very infectious, 1439, 1514–6.
Mere contact with bubonic patient will not give plague, 7512, 17,789–90.
No cases, except pneumonic, observed to be infectious, 9586.
Simple glandular form practically not dangerous, 925, 1165.

See Case mortality.
,, Glandular fever.
,, Infectiousness of plague.
,, Post-mortem appearances in plague.

BUGS:

Bugs and fleas possible agents for carrying infection, 9500–4.
Bugs, influence in spreading disease considered unimportant, I. 378.
No evidence that bugs in hospitals are infectious, 20,640, 20,999.

BULLAE:

Appearance of bullae after acute stage sign of favourable prognosis, 16,816
In the Daman epidemic of 1898 a form of plague noticed, accompanied by bullous inflammations, 16,794.

BURNING:

Bodies:
Hyderabad: Disinfection by burning of bodies, 5155.

Clothes:
Bombay: Clothes of patients leaving plague hospital burnt, 561.
Calcutta: Clothes burnt and compensation paid, 6533.
Hyderabad State: Disinfection by burning of useless clothes and bedding, 5155.
Karachi: Clothes and bedding of people dying of plague in camps invariably burnt, 11,895.
Karachi: Everything in contact with plague patients destroyed in the first epidemic at Karachi, 11,650.
North-West Provinces: Clothing burnt, 9029.
North-West Provinces: The burning of the funeral clothes stopped the spread of plague among the Acharaj, 9460.

Clothes: attitude of natives towards burning of:
Karachi: Burning of clothes objected to by the people, 11,379.
Natives resent their clothes being burnt, 11,379.
Natives believe in infection through clothing, and do not object to infected clothes being burnt 14,724, 14,761.
Natives hide their infected clothes to prevent their being burnt, 24,393.

Floors:
Ahmedabad: Burning of floors resorted to as disinfecting method, 13,923.
Bellary: Floor burning used as disinfecting method, 4419.

BURNING—*cont.*

Burning the surface of mud floors best means of disinfection, 8558, 8699.
Guntakal: Upper two inches of floor dug up and burnt to disinfect, 5117.
Kalindri: Floor burning resorted to as disinfectant, 9894.
Kotri: Disinfection by burning of floors, 12,536, 12,562.
Latrines: Burning grass on floor useful for disinfecting, II. 13.

Houses:
Burning out of houses the surest method of disinfection, 15,178, 20,160–2.
Daman: Burning of infected houses first step taken in 1897 epidemic, 16,388.
Hinganghat: Several houses burned, 5991, 6039.
Hubli: An infected street burnt down, 1645, 1954.
Hyderabad State: Disinfection by burning of houses of imported cases, 5155.
Indian houses, burning the only cure for disinfecting, 15,178.
Jawalapur: Burning of huts, 8934.
Khandraoni: House burning as disinfecting method in, 9650–3.
Khandraoni: All infected houses and property burnt, 9650.
Kumaun: In cases of Mahamari villagers themselves desire houses to be burnt down, II. 362 (262).
N.W.P.: Hut in which plague occurred in camps burnt down, 9168.
N.W.P.: In villages where solitary cases occurred the infected house was evacuated and burnt, 9134.
Panjab: Burning of infected houses limited the spread of the disease in two villages, 10,240.

Houses, inside:
Burning grass on floors inside houses efficient but dangerous method of disiufecting, II. 12, 13.
Dharwar: Insides of infected houses burned, 2331.
Hubli: Houses unroofed and inside burned, 20,162, 20,191.
Kerosene oil method liable to burn houses down, and not complete, I. 442.
Many accidents through kerosene burning in situ, I. 456.

Rubbish:
Burning of infected articles of small value only an insufficient method, 16,155.
Karachi: Rubbish burnt, 81,647.
Malegaon: Evacuated houses disinfected and rubbish burnt, 13,781.
Palanpur: Burning useless articles resorted to, 13,091–4.
Rohri: Everything found in infected houses burnt as a measure of disinfection, 12,029.
Sholapur: Rags and clothes of no value burnt, 23,923.
See Kiln—burning.

BYCULLA JAIL, BOMBAY.

Inoculation with Mr. Haffkine's prophylactic in:
Correspondence with Mr. Haffkine and the Government of India regarding the correctness of the innoculation returns relating to the Byculla Jail, Bombay., III. 658–61.
Effects of inoculation in the Jail, 20,364–79.
Inoculations performed in the Byculla Jail, Jan. 1897, 34–49.
Particulars of inoculation in the Byculla Jail, 17,052–87.
Prisoners not selected for inoculation: inoculated and uninoculated comparable, 20,347–58, 20,360–3.
Report by Lieut.-Colonel Waters, I.M.S., on the inoculations in the Byculla Jail: 17,113.
Statement of ages of the prisoners attacked by plague, 20,380.
Statement of particulars regarding plague and inoculation in the Byculla Jail, Bombay, III. 445–56.

Serum Treatment in:
Treatment of prisoners in the Jail with Haffkine's curative serum, 133, 17,043–51.

CALCIUM CHLORIDE.
Desiccation with calcium chloride kills bacillus of plague in 18 hours, 26,346.

CALCUTTA:
Inoculation with Haffkine's prophylactic in:
Course of, I. 475–7.
Proclaimed as voluntary, I. 468.
Progress of inoculation, I. 476.
Tables of inoculation statistics, I. 476.
Two thousand four hundred and ninety operations, 6572.

Introduction of the infection in 1898.
Cases had occurred before the first detected case though they had escaped recognition, 6471, 6944, 7123, 7482.
First detected case that of a man found dead on 17th April 1898: source of infection not traced, 6430, 6462, 6471, 6608.
Merchandise: On account of precautions taken on railways and length of sea voyage from Bombay, importation of infection in infected articles suggested, 6882.
No evidence of importation by land by a plague patient or person in the incubation stage of the disease, I. 464.
Rail: Evasion of railway inspection and disinfection by persons who came from plague-infected places known to have occurred before the 1898 outbreak in Calcutta, 7481, 7488–500.
Rail: Importation by rail by a person who was sick of plague or had been in contact with the disease improbable, 6882, 7178.
Rail: Information obtained, though without precise details, of a man having come from Bombay and sickened of plague in Calcutta just before the 1898 outbreak, 6701.
Rats: Suggestion that the disease was introduced by rats coming over sea, 7118, 7129, I. 464.
Sea: No evidence that any case of plague came by sea to Calcutta, 7178.
Sea: Suggested infection from the case of a man who came from Bombay by sea in 1897 and fell ill with plague, 7027, 7054.

Plague in 1898:
City declared free of plague, 10th October 1898, 6756.
Clinical history and post-mortem appearances of the first plague cases at Calcutta, I. 465.
Five cases of plague at Manicktolla Hospital; opinion that none were such, 8136–8.
Haffkine's bacteriological diagnoses of bacillus in Calcutta plague cases said to be doubtful, 8203–9.
Historical retrospect and details of the epidemic during middle of year 1898, I. 463–78, 6757.
Number of cases said to be wrongly diagnosed as plague, 8128–233, 8331–42, 8352–6.
Opinion that absence of nervous symptoms in cases diagnosed as plague in Calcutta make their being plague improbable, 8148, 8151.
Opinion that Calcutta cases in 1898 certainly plague, 7315.
Opinion that case of plague at Chandni Hospital really gonorrhœa and malaria, 8161.
Opinion that malarial patient wrongly diagnosed as plague. No bubonic or pneumonic symptoms, 8181.
Opinion that no plague in Calcutta in 1898–9, 8176–80, 8232–3.
Plague bacillus obtained post mortem from nearly all of (15 or 20) the cases tested in Calcutta, 8391–3.
Post-mortem appearance of first Calcutta case, 1898, 6462
Reported plague cases in Calcutta after the town was declared free, 6762–97, 7096.

Sanitary Condition of Calcutta:
Cholera appeared in Calcutta in 1898 and much less than usual, 6878.
Conservancy rendered difficult at Calcutta by coolie strikes, I. 471.
Fearful sanitary condition of ports, I. 464.

Spread of Plague in Calcutta:
Spread of the plague in epidemic form; something in the environment of Calcutta inimical to the, 7627.

CALCUTTA—*cont.*
Statistics relating to Calcutta:
Attacks in various wards of Calcutta, I. 473.
Cases, month by month, 6757.
General mortality rates, 6758.
Mortality in 1898 apparently low, large number left the town, 6548.
Mortality below normal during plague, I. 471.
Mortality in years previous to plague, I. 463.
Plague cases from October 1st to December 29th, 1898, I. 240.
Statistics of population and deaths from plague and general causes, 6518.
Tables, to show that the present mortality in towns near, and districts round, Calcutta is lower than in the five previous years, 6758.

Suspected Cases of Plague in 1896 *in Calcutta:*
Bacillus found in cases during supposed plague shown by Dr. Cunningham not to be the plague bacillus, 6693–8.
Bacillus not found in blood of patients, I. 487.
Bacteria from cases during supposed plague obtained like bacillus pestis, 26,820–32.
Bacteria obtained from cases during supposed plague inoculated into animals which recovered, 26,833–42.
Bacteriological examination of cases during supposed plague in 1896 and opinion that plague bacillus not found in those cases note by Dr. Cunningham, III. 655.
Bepin: Case of double orchitis and glandular enlargement resulting from injury to the foot, I. 491–2, 6723–36.
Bepin: Case of, plague bacillus recovered in pure culture from the case of Bepin, fatal to rats, and said by Mr. Haffkine to microscopically resemble the plague bacillus, 26,908–14, 26,986, 27,009.
Cotta's case; notes on, probably venereal, I. 488–90, 26,817, 26,948–61, 26,997–27,003.
Giga, case of, I. 493–4.
Giga, case of, bacillus like plague recovered from rats connected with Giga's case, 7101–77, 26,895–7, 27,009.
Girl in Bowbazar; case of, 26,919–31.
Glandular fever with enlargements, three case of, 26,919–31.
Golab; case of, 26,892–4.
Heman Shah; case of, I. 491, 26,880–86.
Hodges, Grace; case of, I. 490, 26,875–9.
Marcellies; case of, I. 494, 6845–58, 26,915.
Medical Board, Report on suspected plague in 1896, I. 487–96.
Medical Board Report, disagreement with 1029–31.
Medical Board, Constitution of, 26,818.
Merchandise from Bombay suggested as source of infection in Giga's case, 7101–16.
Opinion that cases which occurred in 1896 not plague, 7028–9.
Presidency Hospital, Calcutta, two suspicious cases in October 1896, I. 491.
Rats: Heavy mortality of rats in Armenian Street, I. 493.
Rats: Notes by Dr. Cunningham regarding mortality of rats, and examination of rats which died during supposed plague in 1896, no evidence of plague among them being obtained, III. 655–6.
Rats: Mortality among rats which occurred during plague in connexion with Giga's case, rats suffering from glandular sickness, and bacillus like plague being recovered from them, 26,898–907.
S.M.N.; case of, 26,887–90.
Shropshire Regiment, cases in, different from ordinary glandular fever, 26,964–85.
Shropshire Regiment; cases in, I. 494–5.
Shropshire Regiment, cases in, bacillus morphologically like bacillus pestis isolated but inoculated into animals without effect, 26,843–67.
Shropshire Regiment, cases in, not plague, 26,843.
Tin Cauri Pal; case of, I. 491, 26,868–74.
See Glandular fever.

CAMPS:
Arrangements in Camps:
Ankleshwar camp, poor maintained in, by the municipal council, 14,228.

CAMPS—*cont.*

Bandra camps, each family had a separate hut, and castes were kept together, 8236–43.
Baroda, camp organisation at, 14,619–20.
Baroda, two kinds of camp at; authorised and unauthorised camps, 14,615–6.
Camps under the trees a great comfort, 10,239.
Castes kept together in camp as far as possible 8214.
Combination of segregation, health and detention camps a more economic and better working measure than a series of separate camps, 18,393.
Cutch, village camps in, 13,445.
Hardwar union, camp arrangements in, 9327–43.
Malegaon, arrangements for camp at, 18,074.
No plague-stricken person admitted in health camp, 12,658.
N.W.P.: arrangements and rules for camps, 9334–41.
Sholapur camps, streets of shops in, 20,259.
Thatched huts erected by Government as a plague hospital in the private camp at Jawalapur, 9341.
Two chappars separated from the camp at Hardwar for observation of suspicious cases, 9336.
Umreth, arrangements for camps in, 14,028–36.

Attitude of the People towards Camps:

Baroda, people in the health camps at, reluctant to go back to town, 14,687, 15,168.
Better surroundings and the absolute safety from infection are highly appreciated by the people, 26,555.
Bombay: Fifteen hundred people pay rent in one camp at Bombay, 8281.
Bombay people, health camps popular with; some prefer to stop and pay rent, 1345, 8273.
Bombay: People object to leave in Bombay, 8275.
Broach: People behaved most admirably in camp, 15,503.
Camp life liked in summer, 15,509.
Jawalapur: Permission to attend the Id and Holi festivals gave no trouble at all, 9343.

Camps provided for the People:

Bangalore: Two hospital camps and health camps at, to accommodate 400 persons, 2550.
Bangalore City: details of accommodation provided for, I. 131.
Bombay: Accommodation of camps in, 1081.
Bombay: Camps provided for evicted people from each ward. 19.
Government huts built with regard to sanitation should be ready, 22,289.
Government huts should be ready to receive the whole population, 22,289.
Hubli: For 2,600 erected at, 1611, 1652.
Karachi: Accommodation for 1,500 persons in segregation camp at, 11,633.
Karachi: Conditions at, favourable for large segregation camps, 11,831.
Poona: Camps erected for infected regiments on Gibbet Hill, 21,251.
Sholapur: Large camps laid out at, at Government expense, 20,231.
Surat: camps provided by Government, 24,419.

Disinfection in Camps:

Ankleshwar: Clothes and effects disinfected on going to camp, 14,224.
Bandra: Clothes not disinfected, 18,600–1.
Bangalore: On removal of persons at segregation camps, disinfection by pouring a solution over them, and afterwards bathing them in water, 3300.
Baroda: Evacuation, accompanied by disinfection of persons and belongings, 14,625.
Calcutta: Property of persons taken to segregation, and isolation camps disinfected on arrival, 6536.
Chipagiri: All persons in segregation camp disinfected before returning to their houses, 4415.
Clothes, disinfection of, should always precede admission to, 24,196.
Dharwar: Contacts disinfected on arrival in camps, 1911.

CAMPS—*cont.*

Effects of people disinfected before return from camp, 11,314.
Evacuation must be combined with the disinfection of the infected area and persons, 10,363.
Evacuation must be combined with disinfection of clothes, 24,193, 24,196.
Evicted people on arrival, disinfection of, 12,657.
Hardwar: Coolies engaged in disinfecting work kept in separate camp with wives and children, 9342.
Hyderabad State: Clothing and bedding boiled on entering and on leaving camp, 5,466.
Karachi: Disinfection of persons effected before removal to camp with good results, 11,143–8, 18,451.
Karachi: Exposure to sun the only method of disinfection used in the Nassarpuri camp, 11,490.
Khandrauni: New clothes given to people in camp before they returned to their houses, 9661.
N.W.P.: People, except at Hardwar, disinfected on going to camp, 9263–5, 9294–7.
Panjab: Before leaving evacuation camp every person given a phenyle bath, 10,049, 10,235.
Panjab: Clothes not disinfected, 18,600–1.
Panjab: Clothes of inmates exposed to sun for ten days, 10,048.
Panjab: Effects of people disinfected after they went to camp, 10,471.
Panjab: People disinfected before removal to camp; good effects observed at Shikohpur and other places, 9993–5, 10,145–6.
Poona: Comparison between cases in which clothes disinfected and a case in which clothes not disinfected to establish the value of disinfection, 21,251–7.
Poona: Contacts sent to segregation camps disinfected, 19,936, 21,272–4.
Proper disinfection and organisation of segregation and other camps preclude the possibility of a camp epidemic, 18,391.
Sholapur camp: Disinfection of all new arrivals, &c., 20,235.

Occupation of People in Camps:

All ordinary handicrafts carried on in the camps at Sholapur, 23,922.
Ankleshwar: People allowed to go into town on business without bad results, 14,225–8, 14,408–9.
Baroda: People allowed to go to their shops for business, 14,632.
Bombay: People allowed to go about their work from segregation camp if back at night, 1354.
Difficult problem to find occupation for the people in camp, 9335.
Hubli: People allowed to go about their daily business, 1652.
Hyderabad: People in evacuation camp allowed to go to town for their business under supervision, 18,119.
Hyderabad villages: Difficulties of evacuation with weavers, 5456.
Jawalapur: All beds and tables used in the plague hospitals made locally in the camps, 9335.
Karachi: People in segregation camp allowed to go to their occupations in town, 11,320–5, 11,433, 11,678, 12,752–5.
Kotri: People allowed to go to the town on business, but not to their houses, 3760–9.
Malegaon: Weavers with their looms taken into the health camp at, 18,075, 13,777.
Nasik: No bad results from allowing people to attend to their occupations in town during the day, 13,809.
People may safely visit the town by day on business if they sleep in camp, 24,197–8.
Restraining the people entirely from going into town during the day for business would be too extreme a measure, 14,405.
Weavers and other handicraftsmen in Savadi camp allowed to go to their work in town, 18,986.

Passes for Camp Inmates:

Bombay: Contacts allowed out from segregation camps on passes, 1356.

CAMPS—*cont.*

Only one pass system in vogue at Hardwar camp, 9337.
Sukkur: People allowed to visit the town only with passes, 3731.
System of permanent and temporary passes in Government camp at Baroda, 14,619.

Provision of Accommodation, Food, &c. by the People:
Broach: About 1,000 people provided camps for themselves, 15,484, 15,502.
Care taken to see that huts are built with regard to sanitation, 19,515.
Cutch Mandvi: People provided their own camps, 13,377.
Entails no cost in small villages; people build their huts themselves of straw, 24,564.
Hardwar: People provided their own huts, difficulties in inducing them to make a camp on a sanitary plan, 8802.
Hardwar: Poor not relieved by charity received rations from Government; but daily distribution of grain to a fixed amount to all who came to ask for it from the Sadabart reduced the camp charges paid by Government, 9335.
Hyderabad State: Villages supply their own camps at suitable places, of which position largely settled by water supply; large camps inadvisable, 5459.
Jawalapur: People provided their own huts, but crowded them too much together, 9178–9.
Palanpur: 8,000 people built huts for themselves, 13,084.
Wardha: People allowed to put up private camps, 6121.
Wise plan to allow the people to put up their own huts. It costs Government nothing, and satisfies the people, 25,823.

See Voluntary Evacuation.

Return of People from Camps to evacuated Houses:
Broach: Evacuated houses sealed up, 15,519.
Dharwar: Measures adopted for the re-admission of the people permitted only after double inoculation, 23,746–7.
If people prevented from returning to houses, plague stops, 8–9.
Impossible to keep people from returning to their houses, 23,171.
Nasik: Impossible to keep the people out of their houses at night, temperature going down to 40°, 14,734.
No cordon around the camps in Palanpur, but roll-call, and people effectually prevented from return to houses, 13,087, 13,164.
People deliberately run risk of return from camps to infected houses in order to see that their property is safe, 22,637–9.
Police patrols and guards necessary to keep people from trying to return to the evacuated houses, but unsuccessful, 13,802, 13,807, 14,229–30.
Prevention of return from camp to village necessary, 20,158, 22,085, 22,604.
Satara: Evacuated houses locked and sealed, and could only be opened at the presence of the authorities, 22,417.
Strict exclusion from evacuated villages depends greatly on the village officers, 22,605.

Supervision in Camps:
Cutch Mandvi: An officer visited the camps each day and brought back cases, 13,423.
Hardwar: A Tahsildar assisted by a patwári appointed superintendent over each camp at, 9334.
Jamalpur: Roll-call of camp occupants made and checked night and morning, 9169.
Karachi: Concealment of cases led to regular inspection of the camps twice a week, 11,886.
Khandesh: Roll-calls made in the camps, 24,557–9.
Khandesh villages: Roll-call proved sufficient without cordon or police in the, 24,562.
Mandvi: From 33,000 to 35,000 persons placed in camp at, and kept under police supervision, 13,423.
No roll-call, but admission and discharge books kept in Malir camp, 12,498.

CAMPS—*cont.*

Palanpur: The village patels made daily roll-calls in the evacuation camps in, 13,165.
Rohri: Eight police to guard 840 people in segregation camp at, 12,061.
Roll-call in Nassarpuri camp, Karachi, 12,772.
Schoolmasters, village officials, and paid enumerators employed in the Kaira district to take the roll-calls, 14,064.
Staff corps officer charged with the supervision of Malegaon health camp took a roll-call twice a day, 13,777.
Surat: Segregation camp at, placed under supervision of a sergeant-major of gunners, 24,417–9.
Umreth: Census, roll-call, and hut inspection segregation camp at, 14,034–6.
Umreth: Golas in segregation camp guarded by police in, 14,033.

Spread of Plague in Camps:
Ankleshwar: Table showing admissions in the segregation camp, and the number of days after admission when the cases occurred, II. 239.
Bangalore: Plague cases among Sepoys, 4889.
Bangalore: Segregation of contacts at; admissions and deaths in camp, 2621, 2941, 25,028.
Baroda: Nine cases in camp among 11,000 people, 14,624, 14,672–5.
Bellary: No plague cases in, 4403.
Bombay: Details of segregation camps at, III. 117, 118.
Bombay: Very little plague among contact in camp, 1200, 1248, 1355.
Bombay: Very little plague in segregation camps, comparatively, 1355.
Camp, Malir, no case incurred from infection caught in the, 12,438.
Camps, in voluntary camps, unlike houses where four or five people get plague in one house, more than one case not observed in huts, 11,892.
Cases do not communicate infection as much in camps as in towns, 14,659-61.
Cases in camp among people who had been out less than 10 days or had slept away, 17,295.
Contact cases do not spread in camp, 23,349–50.
Cutch Mandvi: Borahs go into camp at, and suffer little, 475.
Cutch Mandvi: Cases numerous among contacts in first epidemic but no record kept, 13,380-1.
Cutch Mandvi: Number of cases in camps in second epidemic, 13,437-40.
Cutch Mandvi: Table of cases in the segregation camps at, 13,542.
Dharwar: Contact or segregation camp at, details of numbers admitted, 1902.
Dharwar district: Mortality in segregation camps very small, 1653.
Dharwar: Details for villages exhibiting effects of evacuation, 23,167.
Disease continues in camp because people are housed in insanitary huts, 22,291–6.
Dropping cases in camp only among people who slept in evacuated houses, 10,191–3, 13,807–13.
Duration of plague after evacuation not dependent on rainy or dry season, 22,704.
Hardwar: Four cases only in contact and segregation camps, 8797.
Hinganghat: Statistics of segregation and other camps, I. 23.
Hyderabad Sind: Eighteen cases in contact and eight or nine cases in other camps, 18,125.
Jawalapur: Among 13,000 people taken in camp at, only 69 cases during the whole period, 8796–7.
Jawalapur: Huts too close together, and overpopulated: otherwise there would have been less plague, 9178.
Jawalapur: Table of average weekly population of contact camps at, and weekly number of plague attacks, II. 45, 9.
Karachi: A case in camp traced to visit to town, 12,776.
Karachi: A few cases where huts too close together, 11,263.

CAMPS—*cont.*
Karachi: Kiamari: Only three plague cases in Government health camp at, in 1897, 11,969.
Karachi: Plague in health camp as bad as in the most infected parts of a big town, 21,752.
Karachi: Plague statistics from the Nassarpuri camp in 1897, II. 155.
Karachi: Statement of total attacks and mortality in voluntary camps, from May 1st to August 14th, 1898, 11,893.
Karachi: Table of average population in contact camps at, with the number of plague cases and deaths, 11,628, 11,671-2, II. 148, 155.
Karachi: Table of plague mortality in the unevacuated portions of the town, from April 1st to November 4th, 1898, II. 154b.
Khari, near Bandra: No cases among about 1000 people in camp, 18,936.
Kotri: Cases in camp due to communication with the town, 12,645.
Kotri: Only one plague case in contact camp at, 12,570.
Kotri: Statement of cases in the various camps at, 12,643.
Molagavalli: One thousand five hundred people go out into the fields at; cases continue, 5000-4.
Mysore: Statement of cases in contact camps, III. 276.
No fear of plague becoming epidemic in camps, 18,391.
Palanpur: Details for villages showing effects of evacuation, I. 199 (13,159).
Panjab: Details of cases occurring more than 20 days after evacuation in several villages, II. 81-2 (9981), II. 105-6 (10,384), II. 116-7.
Panjab: Information concerning persons attacked with plague more than 10 days after evacuation of the villages, (10,603) II. 115-6.
Panjab, Mahlgahla: Statistics relating to history of plague, II. 103-4.
Panjab: The majority of cases occurring 20 days after evacuation ascribed to the people having returned to the village surreptitiously, 10,515-28.
Panjab: Want of cordons around the villages cause of plague in the camps, 10,758.
People in camp infected by re-visiting their houses, 9, 11,890, 12,230, 12,795, 13,456, 13,729, 13,807, 18,075, 22,601, 24,155.
Plague dies out in camp in a week, 20,451.
Poona: Particulars of cases in camp among the regiments, 21,252.
Poona: Statement of cases in segregation camp, 21,539.
Poona: Statement of cases in segregation camps since February 14th, 1899, 21,832-5, III. 317.
Porbandar: Statement of cases in contact camps, 13,722.
Porbandar: Table showing daily attacks and deaths among the Kharwas from date of evacuation, II. 221.
Porbandar: Table showing number of cases in evacuation camp, II. 253a.
Proper organisation of segregation camp and proper methods of disinfection exclude the possibility of a camp epidemic, 18,391.
Sholapur camp kept entirely free from plague, 20,234.
Sholapur: Table of cases among the evacuated population, 23,940.
Sholapur: Table showing progress of plague week by week in the city and health camp, III. 109.
Sirohi: Cases in camp at, 9836, 9865, 9877.
Surat: Camp cases occurred in those who visited the town, 15,776.
Surat: Majura Health Camp, average population, 3,754; only 15 cases in camp, 15,775.
Surat: Table showing mortality in health camps at, II. 304.
Timmencherla, no cases in camp at, 4129.
Wardha: Statistics of segregation and other camps, I. 224.

CAMPS, OBSERVATION:
Dharwar: Observation at, for people from infected localities, 1927.

CAMPS, OBSERVATION—*cont.*
Dharwar: Observation camps closed November 1898 at, as useless, owing to spread of infection in district, 1930.
Hardwar: Pilgrims from infected areas conducted to the special camp at Hardwar, and medically inspected morning and night, 8751.
Hubli: 10 days' detention for all arrivals in, 2429.

CAPSULE:
Bacillus of plague not found with a capsule, 5791-8714.

CARBOLIC ACID:
Clothes, Disinfection of:
Clothing disinfected at Ankleshwar by placing it in carbolic acid lotion for half an hour or simply boiling it in water, 14,255-7.
Efficacy:
Action of the phenols and their allies on the bubonic microbe, II. 5.
Bacillus cannot live in Haffkine's fluid because of the carbolic acid, 8411.
Bacillus of plague killed by two per cent. carbolic acid in three minutes, 27,401.
Bacillus of plague killed by ½ per cent. of carbolic acid, 105.
Experiments with:
Experiments on the effect of carbolic acid in destroying micro-organisms on a wall gave no satisfactory results, 26,351.
Results of tests with carbolic acid, II. 5.
Inefficacy:
Plague bacillus not sensitive to the action of carbolic acid, II. 5, a.
Perchloride of mercury at Calcutta, carbolic acid given up in favour of, 6528.
Phenyle more active than carbolic acid on the microbe of plague, II. 5.
Person, Disinfection of:
Carbolic acid in solution strong enough to kill bacillus would hurt people so much that they could not stand it, 4305.
Persons disinfected in carbolic bath at Ahmedabad, 13,896.
Plague patients receive carbolic bath on leaving hospital to disinfect them, 557
Poona: Persons on entering camp bathed in carbolic at first, but, at a later period, in phenyle, 21,272-4.
Where used:
Common Jail, Bombay, used in, as disinfectant, 20,344.
Daman: Disinfection by crude carbolic acid diluted with water, in strength of 1 in 40, 13,629, 16,409.
Palanpur: Carbolic acid resorted to as disinfectant in, 13,091-4.

CARBONIC ACID GAS:
Experiments on the growth of the plague microbe in air with admixture of carbonic acid, 18,893.
Experiments to recover the plague bacillus from earth by cultivation in carbonic acid gas, 26,144, 26,233-4.
The carbonic acid method the only successful way to isolate bacillus of plague from earth, 26,179.

CARBUNCLES:
Carbuncle, which in one case was point of entry of infection, contained multitudes of bacilli of plague, 6910.
Carbuncles observed, 7302, 12,875.
Details of 10 cases of plague with carbuncles, 12,360-74.
Lymphatic glands enlarged in about half the cases of primary carbuncles, 12,487.
Microbes resembling plague bacilli discovered by microscopical examination of the serum of a plague carbuncle, 12,377.

CASE MORTALITY:
Ahmedabad: 66·6 per cent. of the imported cases proved fatal, 13,907.
Ankleshwar: Totals of cases and deaths in the town and district, 14,214.

CASE MORTALITY—*cont.*

Baroda Cantonment: Cases and deaths, 15,424–6.
Baroda City: Total cases and deaths, 14,637.
Baroda State: Number of cases in villages with results, II. 517, App. R.
Bhiwandi: Attacks and deaths, 14,482.
Igatpuri: Table of cases and deaths, III. 90.
Ilkal: Table of cases and deaths, III. 90.
Jawalapur: Number of cases with results, 9539–40.
Kotri: Per-centage of recovery cases, 39·8, 12,638, 12,649.
Palanpur: Total attacks and deaths, 13,159.
Panjab: Cases and deaths, 10,330.
Panjab: Jullundur district: Plague mortality, 62·73 per cent., 10,205.
Porbandar: Total of cases with results, 13,692.
Mortality greatest in septicæmic, next in pneumonic, and least in bubonic plague, 12,391.
Remarks of the Bombay Plague Research Committee on case mortality, I. 382.
Satara: Mortality during first epidemic, 66 per cent., 22,259.

See Hospitals.

CASTE AS AFFECTING LIABILITY TO PLAGUE:

Ankleshwar: Table showing proportion of attacks in the principal sub-classes among the Hindus, II. 246*b*.
Ankleshwar: Table showing number of cases classified according to the population of each caste, II. 246*a*.
Bangalore: Table of number of seizures and deaths by races and castes in the Civil and Military Station, I. 109, 25,015.
Bangalore Hospital: Relative mortality according to castes, 2913, 2923.
Baroda State: Plague cases according to sex and caste in, 14,989, 15,219.
Bombay Hospital: Table of mortality among castes and races, I. 391.
Bombay, Parel Hospital: Incidence of cases by sex, age, and religion, 7221.
Calcutta: Incidence of plague by age, race, and sex at, I. 474.
Calcutta: Table of attacks and deaths according to the classes of the population, I. 474.
Caste does not influence mortality, 10,210.
Deaths among different castes, I. 306.
Disease spreads in circles of castes, 16,006.
Immunity of particular castes depends on their habits as to fresh air and cleanliness, 22,274.
Incidence of plague on various castes, I. 378.
Karachi: Statistics of plague cases in the hospital, with reference to caste, 12,358.
Karachi: Table of number of cases and deaths, according to castes, in the municipal limits, II. 157.
Karachi: Table showing, by castes, attacks and deaths of plague during the last six week of the epidemic, II. 157.
Mysore City: Castes and plague in, 25,015.
No difference in the mortality of people from habits, caste, or age, 10,210.
No difference in the predisposition to plague of certain classes, 16,315.
Observation on immunity in different castes during the present epidemic, 22,264–7.
Observations on plague incidence in different castes at Bombay, 17,681–5.
Porbandar: Statement showing plague cases and deaths among the various communities from May to November 1898, II. 222.
Spread of plague at Dharwar and Hubli was not marked by an inter-connexion of castes, 1715–7.
Statistics of plague cases in the Sassoon Hospital bearing on caste, sex, and position of buboes, 12,897.
Surat: Castes and plague at, 2046–8.
Surat: Number of plague cases according to castes, 15,632–3.
Surat: Table of mortality from plague among the different castes, II. 295.
Umreth Town: Table of total attacks and deaths by caste, sex, and age, II. 233.
Very dirty classes, such as Dhers and Mangs, not so liable to plague, 5478.

CAT:

Affected by Plague:

Ahmednagar: Cats seen suffering from plague, 24,310.
Ahmednagar: Overrun with cats having open buboes in their necks, 18,990.
Bandra: Cats had plague, 19,095.
Baroda: Glandular swellings below the jaw noted in a cat, 14,641.
Bombay: Cats suffered from plague, 1187–8, 20,423.
Cutch Mandvi: Cats died of plague, 13,565.
Kaira: Cats died of plague, 14,079.
Karachi: During the first epidemic cats were found with buboes and killed in large numbers, 11,311, 11,839.
Umreth: Suspicious deaths among cats, 14,079.

Discovery of Bacillus in:

Found in cats with typical plague symptoms, 20,424.
Involution forms of plague bacilli seen after death at the seat of inoculation in a cat and guinea pig, 26,227.

Immunity from Plague:

Cats inoculated with large doses die of plague, 26,316.
No evidence that cats are affected by plague, I. 378.

Infection by:

Masur: Instance in which plague was probably caught from a cat, 14,484.

Reaction of Plague Virus in:

Cat inoculated with plague virus showed more local reaction than any other animal, 26,316.

Theory that Plague not recently imported to India:

Plague cases said to follow on a cat suffering from bubo in Bombay in 1893, 18,276.

CATTLE:

Diplo-Bacteria found in:

Diplo-bacteria similar to those found in plague rats discovered in the blood of cattle during the epidemic among them at Calcutta in 1897, 26,942.

Disease among:

Foot-and-mouth disease among cattle just before plague outbreak in Bombay, 901.
Great mortality among cattle in Bombay in middle of 1896. 27,016.
Mesenteric glands were perfectly black in animals dying of the Calcutta epidemic in 1897, congested and enormously enlarged, 26,944.
Outbreak of a disease among cattle, the symptoms of which were different from rinderpest, in January 1897, in Calcutta, 26,941.

Housing of:

All villagers inclined to keep cattle and manure close to their houses, 7922.
Baroda: Cattle and men live all under same roof, 15,193.
Cattle in one enclosure with living rooms at Pali, 6423.

CATTLE—*cont.*

Cows kept in filthy state in Kumaun dwelling-houses, 6163.
Cutch Mandvi: Cattle kept by the people of, in the lower rooms of the houses, 13,353.
Dharwar district: Kept in the dwelling-houses in all the villages in the, 23,180, 23,431, 23,518.
Housing of cattle in human dwellings a confirmed habit which cannot be altered, 7922.

CENSUS.

Dharwar:

Differences between figures of census and inoculation registers, 1764-7.
Error in statistics, because inoculated people come in from the huts outside to die in their houses, 2351–9.
Lowest population of Dharwar 9,000, 1972.
Margin of error in the census returns of inoculated and uninoculated, on account of the people having left the town, 1974–2001
Weekly census in Dharwar since October 19 1898, 1763.

Gadag:

Census taken under the directions of Mr. Vincent, and checked once a week by supervisors, 23,832–6, 23,853–62.

Hubli:

Census checked every week by supervisors, who each had a ward of about 100 houses; tested for the whole of Hubli by one European officer, 3174–8.
Census figures obtained by an enumeration and subsequent deductions and additions, and approximately correct, 3123–30, 3166–7.
Census figures probably under the figures of actual population; lowest population of Hubli probably 6,000 to 8,000, 2488–92, 2518–9.
Census kept up to date by daily inquiries regarding arrivals and departures by supervisors, 1959.
Census made once for all, and verified periodically by additions and subtractions to keep it up to date, 2523–7.
Census stated whether persons were inoculated or not, and, in spite of difficulties, was fairly accurate, 3179.
Census taken in December 1897, under the directions of the Collector, no European being employed in connexion with the taking of it, 20,172–6.
Census taken weekly, but attempts made at concealment, 2520–1.
City divided into 10 sub-divisions, each division having about 10 supervisors who each looked after 90 or 100 houses, 19,796–8.
Difference between Captain Leumann's figures in his inoculation report and census figures due to the fact that the former refer to periods which do not accurately agree with those of the census, and were corrected by special inquiries, 25,143–50.
Discrepancies between figures in census and figures given by Captain Leumann in his Report on Inoculation in Hubli, 3056–65.
Each supervisor took the census for 100 houses, probably taking a week over the work, 20,181–3.
Lowest uninoculated population, about 3,000 or 4,000, 19,849–51.
Margin of error in statistics of inoculated and uninoculated, on account of people having left the town, 1987–2001.
Number of uninoculated persons probably never went below 5,000, 23,461–2.
Original census kept up to date by subtractions for deaths and departures, and additions for arrivals; result fairly accurate, 19,841–6.
Plague census taken first in October 1897, in exactly the same way as the Imperial census, and figures fairly accurate; the uninoculated population not as great as 5,000 at its minimum, 25,157–60.
Rains prevented supervisors from doing their work properly, and many, being volunteers, ran away from fear of plague, 1589.

CENSUS—*cont.*

Supervisors check the census every week, each having a ward of about 100 houses, 1623, 1665–6.
Supervisors visited houses in their wards every day, the town having 12,000 houses, and each ward having about 100 houses, 20,165.
Uninoculated persons tried to keep their names from being recorded in the census register, 19,890.
Uninoculated persons had no inducement to get registered, 3169–71.
Uninoculated population arrived at by deducting numbers of inoculated reported to be present from census returns of total population, 2490, 2523.
Ward supervisors went to every house once a week, to check the census; returns, when tested, found fairly accurate, 19,870–3, 198,91.

See Roll-call.

CHAMARS:

Chamars frequently attacked, as they are not only workers in leather, but also the servants of the village; and hence in close contact with plague patients, 10,319.

CHARACTER AND PREPARATION OF HAFFKINE'S PLAGUE PROPHYLACTIC.

See Haffkine's plague prophylactic.

CHARACTERISTICS OF BACILLUS OF PLAGUE.

See Bacillus of plague.

CHILDREN:

Clinical feature of Plague in:

Clinical description of plague case in a child, 7587.
Convulsions prominent symptom in plague-stricken children, 5075, 12,987.
Half the number of cervical buboes occur in children under 12 years of age, 12,397.
Prognosis better than among grown-up people, I. 352.
Temperature rises more quickly and is greater in children than in adults, 20,689.

Medical Treatment of:

Administration of carbolic to children causes gastritis, 11,934.

Mortality of Children:

Infinitesimal death-rate from plague among children under one year of age, 11,815.
Jullundur District: List of villages where children under two years suffered from plague, II. 103.
Karachi: Many die after epidemic at, 4310.
Karachi: Table showing infant mortality after first epidemic of plague, II. 156.
Karachi: Table showing ordinary mortality of infants from 1894–8, II. 156.
Mortality from measles and influenza in Poona heavy among children under five during January and February 1899, 25,838.
Pneunomic plague always fatal in, 12,314.
Surat: Plague mortality among children 40 per cent., 15,643.
Surat: Table of mortality among children from small-pox and measles, II. 301.

Plague and Children:

Baby at the breast of plague patient escapes infection, 7407.
Cases of children under two years of age in the voluntary camps at Karachi, 11,890.
Childhood chiefly immune from plague, 14,395.
Children at the breast little liable to the infection, 10,329.
Children under one year of age generally escape plague, 11,739, 11,815.
Mild case of plague in children, 9467–75, 10,338.
More or less immune from plague attacks or fatal terminations, 23,061.
Only one case seen among infants, 5926.
Plague rarely attacks young children, 15,446.

CHILDREN—*cont.*

Very few children under five contract the disease, 16,510.

See Age.

„ Inoculation of Haffkine's plague prophylactic: *Age and inoculation; Bars to inoculation;* and *Dosage.*

CHLORINE:

Plague bacillus killed by freshly electrolysed water with chlorine in solution, 3632.

CHLORO-NITROUS OZONE:

Used as disinfectant: statistics of results, II. 258.

CHOLERA:

Decrease of:

Ahmedabad: Cholera has disappeared from, since the introduction of the new water supply, 13,962.

Calcutta: Cholera diminished by introduction of good water into, 6998.

India: Cholera in, much diminished of late years, 8061.

Mysore: Cholera has disappeared since the new water supply was introduced, 25,129.

Disinfection:

Very little disinfection done in cholera epidemic. The only provision made is the distribution of medicines, 8015–6.

Notification of:

Promptly notified, 7818.

Reports of cholera cases more easily obtained than those of plague, 8876.

Outbreak of:

Appeared late in Calcutta in 1898, and much less than usual, 6878.

Poona: Cholera and plague at the same time during the first epidemic, 21,679.

Surat: Sudden outbreak of cholera and plague in jail, 15,789.

Severity of:

In cholera, as the outbreak proceeds, cases become milder; the reverse holds true of plague, 6938.

CIVIL MEDICAL DEPARTMENT:

Assistant surgeons are trained at Calcutta or Lahore, generally intelligent men, 7775.

Civil Medical Administration in the Bombay Presidency, system of, 17,147–56.

Doctors do two years' army medical work before going to Civil Department, 7903.

Emergencies: Methods of securing additional help, 7967.

Hospital assistants officer small hospital and dispensaries, and are mostly educated in the vernacular, and have only moderate qualifications, 7773–82.

Military duty, liability to, does not deter men entering the Indian Medical Service, 7953.

Number and duties of medical officers in the N.W. Provinces, 8928, 8971.

Officer in charge of dispensary might be utilised for checking returns of mortality, 10,292.

Organisation of medical body in India, I. 272–86.

Promotion: Medical officers if put to special scientific work would lose best chances, 8011.

Question of control over Civil Surgeons by Head of Civil Medical Department, and also by Head of Sanitary Department, 7960–6.

Staff insufficient to deal with plague; local and temporary men were employed, 7915.

See Civil Surgeons.

„ Health Officers.

„ Sanitary Department.

CIVIL SURGEONS:

Civil Surgeons greatly assist the Municipalities with their advice on sanitary measures, 17,204.

Duties of the Civil Surgeon of the Bombay Presidency and the Civil Surgeon in other parts of India, 17,140–4.

CIVIL SURGEONS—*cont.*

Duties of the Civil Surgeon of the district, 10,512.

Duties of Civil Surgeon in ordinary circumstances do not go beyond suggesting improvements in sanitation, 22,507.

Many pressing calls on Civil Surgeons, so that they cannot properly scrutinise death returns, 7811–4.

Multifarious duties of the Civil Surgeon leave him no time to direct plague measures, 7730, 7912–4.

No longer recruited from Uncovenanted Medical Service. The vacancies filled up either by Military or Civil Assistant Surgeons, 7731.

CLIMATE.

See Meteorological conditions.

CLINICAL FEATURES OF PLAGUE:

Aberration of mind a symptom of plague, 4547.

Aphasia a symptom of plague, 21,029.

Aphasia not noted among the patients in the Sassoon Hospital, Poona, 12,905.

Appetite, varied, 20,841.

Arthritis in 4 or 5 per cent. of the cases, 20,907.

Blisters observed, in a few cases all over the body, 20,873, 21,020.

Cardio-vascular symptoms: Peculiar symptoms in circulatory system a clinical feature of plague, 20,800.

Cardio-vascular symptoms: Throbbing of the carotids a clinical feature of plague, impulse at the apex more diffuse than normal, I. 380.

Central deafness, 20,793.

Cerebral symptoms grave in cases where no bubo appeared, 12,897.

Convulsions in children, 20,786.

Convulsions prominent symptom in plague-stricken children, 5075, 12,987.

Delirium, I. 380.

Delirium, character of, 20,756–8.

Diarrhœa generally just before death, 20,850. I. 380

Disturbances in the circulatory, respiratory, digestive, urinary, and reproductive systems, I. 381.

Dysentery, a clinical symptom of plague, 511.

Epistaxis seen in plague cases, but only if complicated with relapsing fever, 20,809.

Erysipelas noted especially in cases of cervical buboes, 20,723.

Expression: peculiar facial expression a clinical feature of plague, 12,398, 15,294, 20,673.

Gangrene and blebs observed in Daman, 16,750.

General description of clinical symptoms of plague in a child, 7587.

General description of clinical symptoms in the different forms of plague, III. 44, 1386, 20,404–7, I. 379.

General description of cases in Sassoon Hospital, Poona, 12,897–905.

General features of plague cases, I. 58–63.

Hæmorrhage in the bowels and stomach, 20,854.

Hiccough persistent, defying all treatment, 20,848.

Leucocytosis a clinical feature of plague, 20,803.

Liver not enlarged, 12,412.

Liver in bubonic plague somewhat large and congested, 10,421.

Locomotor system: staggering gait a characteristic early symptom of plague, 12,898, 15,294, 20,668.

Mania in two cases accompanied an attack of plague, 20,791.

Melæna, 20,852.

Meningitis, 13,046.

Nausea a clinical feature of plague, I. 380.

Nervous disturbances, 12,987.

Nervous prostration, I. 379.

Nervous symptoms most prominent among Europeans in Sassoon Hospital, 12,934.

Onset and progress differ enormously in different cases, I. 351–2.

Paralysis, I. 380.

Paralysis and hemiphlegia, 16,766.

Partial laryngeal paralysis, I. 380.

Petechiæ observed all over the body, like a rash, but not a characteristic sign of plague, 20,883.

Petechiæ not observed in pneumonic form, I. 369.

Position: peculiar flexed position of patients 7015.

Pulse feeble and dicrotic, but of varying character in different patients and different stages of an illness, 20,800.

CLINICAL FEATURES OF PLAGUE—*cont.*

Pulse similar to that of aortic regurgitation, 21,035.
Pulse small, easily compressible, and frequent, 12,398.
Renal complications: albumenuria, 10,422, 12,409, 15,300.
Renal complications: hæmaturia, 15,307.
Respiration hurried and oppressive in cases without bubonic swellings, 12,897.
Respiration hurried, I. 380.
Respiration generally hurried, voice disconnected and slurring, 12,399.
Respiration in pneumonic cases much more hurried than in other forms of plague, 12,914.
Skin: cellulo-cutaneous necrosis, 20,875.
Skin: cutaneous manifestations of plague, 20,868–73.
Skin: no local affections of the skin observed in cases of plague, 9571.
Skin: phlegmonous condition of the skin in cases when no bubo appears, I. 351.
Skin dry and harsh in plague, I. 380.
Smell: bubonic cases characterised by bad, 7015.
Smell: peculiar, 20,892–4.
Speech: aphonia very common, 12,402, 12,901, 16,527, 17,581.
Speech: eight cases of absolute aphonia; recovery, 12,400.
Speech: no aphonia noted among patients at Sassoon Hospital, Poona, 12,905.
Speech: thick, I. 379, 15,295, 20,675.
Speech: voice disconnected and slurring, 12,399.
Spleen: no abnormal symptoms in spleen, 12,411.
Spleen in bubonic plague very much enlarged and congested, 10,421.
Symptoms of the enteric form, 18,543–9.
Symptoms of typical cases at Wardha, 6291.
Table showing special symptoms in 100 consecutive fatal cases and 100 consecutive recovery cases, II. 176*b*.
Table showing special symptoms in 100 consecutive fatal cases and 100 consecutive recovery cases, II. 176*b*.
Tetanus observed in plague cases, 20,770.
Thirst marked, 20,841–3.
Tonsil: pseudo-diphtheritic membrane on, 20,813.
Urine diminished in quantity, of high specific gravity and intensely acid, I. 38*c*.
Vomiting, 8221, 12,398, I. 380.
Vomiting, bilious, 20,844.

CLOTHES:

Bacillus of Plague: isolation from clothes:
Failure to isolate it from clothing, 619–20, 635, 995, 8627–8, 25,347–51.
Never found in clothes worn by plague patients, 25,347.
No method for identifying the microbe in articles of clothing, 8537.
Once found in a piece of soiled matting which had been used by a plague patient, 35,393–6.
Plague cultures said to have been made from clothes, 7559.

Bacillus of Plague: vitality in clothes:
Bacillus of plague kept alive in clothes indefinitely, 10,094.

CLOTHES—*cont.*

Disinfection of Clothes:
Comparison between case of evacuation with disinfection and case of evacuation without disinfection at Poona proves value of disinfection, 21,251–7.
Disinfecting of personal clothes, very useful, 10,921, 23,187.
Effect of disinfecting clothes at Kalankot and Gharibabad, 11,144, 11,162.
Effect of disinfecting clothes in Shikohpur, Panjab, and other places, 9994, 10,145–6.
In Kankhal and Jawalapur infected effects taken to camp without disinfection, and soon ceased to be infective, 9294–7.
Natives conceal infected clothes in order to prevent their disinfection, 8780, 9224, 9256, 24,393.
Personal disinfection more disagreeable to the natives than the disinfection of clothes, 21,510
Villagers bribe disinfectors to save their kit from being put into perchloride, 21,174–5.

Infectivity of Clothes:
Case of probable infection by clothes, 320.
Case of infection at Karachi through clothes that had three months before belonged to a man who died of plague, 11,961.
Case of infection through effects of a dead man, 2107.
Cases of infection at Dharwar Hospital from pneumonic sputum on clothes, 1892.
Cause of plague case at Multan traced to clothes sent from Bangalore, 10,871–99.
Clothing brings infection to Hardwar, 6435.
Clothing destroyed, and no further infection in Bangalore Hospital, 2894.
Clothing stolen from dead bodies infected a whole family at Satara, 22,024.
Clothes, one of the only factors which has proved infective, 21,717.
Danger of infection through clothes much less than through bags containing grain, in which rats would nestle, 994.
First case at Kariam traced to infection by clothes, 10,394.
First case at Kulewal traced to infection by clothes, 10,747.
Infection carried to village near Satara by clothes stolen from bodies of the dead, 22,527.
Infection carried by clothing in Hubli, 3121.
Infection carried by wearing apparel, 8885–90.
Infection carried by property from infected houses, 24,391–8.
Infection conveyed by clothes from plague corpses, 23,011.
Infection conveyed by clothes stolen from plague patients by temporary attendants, 23,957.
Infection from clothes given to Mahars, 24,084.
Infection probably due to clothes, 2107–14, 9271, 10,081, 10,082–93, 10,397–8, 10,754, 11,333, 12,712, 12,731, 12,997–8, 14,347, 15,170, 15,202, 17,994, 18,129, 18,502, 19,028, 20,066–74, 20,076, 22,572, 22,878.
Plague introduced at Hardwar in the clothes of a person from Karachi, 8911.
Plague infection may harbour for a considerable time in clothes kept in the dark; case in camp on opening box of clothes brought out seven days before, 9483.
Probable case of infection by clothes at Thana of Parsee lady, 320.
Rats, clothing, and some unknown agent in the retail grain shops are the chief causes of the spread of plague, 11,278.
Supposed case of infection from clothes at Rahon after the people returned to the town

Clothes—*cont.*

free from plague, having been 28 days in camp, 10,562.

See Acharj.
,, Dhobis.
,, Domes.

Infected Clothes concealed :

Natives hide infected clothes and this probably causes spread of plague, 8780, 9224, 9256, 24,393.

Opinion that Clothes by themselves not very infective :

Clothing cannot spread disease without human agency, 10,328.
Clothing not very infectious to hospital attendants, 237.

COLD WEATHER :

Baroda : In the cold weather plague showed a tendency to spread a little in camps, 15,111.
Baroda : People crowd their houses in the cold weather and plague is then worst, 15,240–3.
Bombay : Epidemic increases during the cold weather owing to the people sleeping more indoors ; 350,000 people sleep in the streets in the hot weather, 26,104.
Bombay : In cold weather natives sleep in their houses huddled up together and are more liable to plague, 550, I. 378.
Bombay : Virulence of the plague attributed to the excessive cold weather, 1032.
Bombay : Virulence of the plague in the third epidemic, and the prevalence of the pneumonia form, must be attributed to the excessive cold weather, 17,888.
Broach : The habit of the people to sleep outside their houses in the hot weather the reason that the plague remained dormant in May and June, 14,385.
Kolaba : Plague increased in each of the epidemics in the cold weather, dropped as the hot weather came on ; during the rains there were no cases at all, 17,650.
North winds prevailing in cold weather cause that part of the town which the wind reaches first to be first attacked by the disease, 10,844.

COLI-BACTERIUM :

Plague bacillus appears to be at antagonism with bacterium-coli, 1531.
Tests on the effect of bacillus coli on the growth of the plague bacillus proved it to have some retarding influence, 26,150.

CONCEALMENT OF PLAGUE CASES :

Causes of :

Disinfection, wholesale, and evacuation led to concealment of cases at Surat, 16,004.
Enforcement of restrictive measures led to the secreting of the dead and the running away of the people, 17,864.
Evacuation impossible in a big city ; only leads to concealment of cases and frightens people away, 7854, 8272.
Female cases, concealment of, tends to make statistics doubtful, 6576.
Ignorance, concealment of cases mostly due to, 16,137, 17,949.
Plague measures, objection to, so great that people will not report cases, 7824.
Police activity in discovering cases objected to, I. 469.
Segregation leads to concealment of cases, 2672, 3390, 3480.
Too strict measures and compulsory segregation would lead to concealment of cases, 12,822.
Undiscovered cases most dangerous source of infection, 10,994.
Worrying the people about sending their patients to hospital leads to concealment, 25,806.

Extent of :

Bandra : General disinclination in the district to give information, 18,956.
Bangalore : Concealment even among the officials and the more intelligent part of the people, 3288.

Concealment of Plague Cases—*cont.*

Bangalore : Greatest concealment among Muhammadans, 2993, 25,022.
Bangalore : Information of cases usually not given till after death, 2604, 3348.
Bangalore : Serious concealment and throwing out of dead bodies due to application of segregation and plague measures, 2593, 2604, 2671, 2696, 3223, 3282.
Bombay : Cases concealed, 487–9, 4033.
Bombay : Dead bodies spirited away, 10,954.
Bombay : Difficult to get information in Mussulman districts, 1349.
Bombay Plague Committee, great difficulty in ascertaining number of plague cases under the, 17,862.
Calcutta : Low mortality in, not attributable to concealment of cases, 6758.
Calcutta : Probable concealment makes statistics unreliable, 6555, 6576.
Cases concealed and carried from house to house, 489, 6599, 14,603, 16,229–32.
Daman : Bodies found in an advanced state of decomposition, 16,392.
Guntakal : Concealment of cases by Muhammadans, 4197.
Hubli : At beginning cases fully reported, but system broke down later, 19,799–803.
Hubli : Dead bodies found in the streets, 3079–81.
Hubli : Good many cases escaped record, 1590.
Hubli : In camps deaths escaped record, 1981.
Hubli : In one house 9 out of 13 inmates died of plague before the authorities knew the house was infected, 23,383.
Hubli : Plague mainly notified after death, 19,836.
Kankhal : Cases in Muhallah camp reported, but at Jawalapur efforts were made to conceal them, 9345.
Karachi : Concealment of deaths impossible, 11,183.
Karachi : Concealment of cases led to regular inspection of the camps twice a week, 11,886.
Karad : Plague concealed for two months, 21,060.
Khandraoni : Plague existed in the village for two months before it came to the notice of the authorities, 9697.
Panjab : Organised arrangements for concealment of cases in the villages, 9948–57.
Poona : Concealment practically impossible, staff being very strong, and working from daylight till dark, 10,913.
Rohri : People hiding with their sick in the date plantations hunted out by mounted men, 12,117.

Measures to prevent :

Belgaum : Non-removal of patients and contacts in second epidemic caused people to give accurate information of cases, 23,138.
Bombay : Under the present system of not removing patient to hospital except by the desire of his friends, concealment of cases is the exception, 25,815.
Bulsar : Concessions given to inoculated prevented the concealing of cases, 16,291.
Mysore : Under voluntary system cases mostly detected, 24,969.
Surat : Concealment punished by removal to general instead of caste hospital, I. 257.
Surat : Concealment of cases threatened with removal to Government hospital, 13,157.
Surat : Segregating neighbours of plague cases not reported, resulted in voluntary report of 230 out of 281 cases, 16,029–32.
Surat : Ward system broke up the conspiracy of silence as to plague, 16,004.

CONSTITUENTS OF HAFFKINE'S PLAGUE PROPHYLACTIC :

See Haffkine's plague prophylactic.

CONTACTS :

Difficulty in securing :

Difficult to trace contacts, 18,934.
Impossible to get hold of the contacts in a crowded chawl, 8261.
Vigilance Committee fail to remove contacts, 7610.

CONTACTS—*cont.*

Not removed:

Bombay: District medical officers have no power to remove contacts, 7610.
Bombay: Not a single case among contacts in, after thorough disinfection of room where patients had died, 25,803.
Daman: Contacts left in the house, 16,369.
See Treatment of the sick in their own houses.

Number segregated:

Average number of people to be segregated, four or five per case of plague, 310.
Bangalore: Instead of three or four contacts per family less than two found on the average, 3351.
Bombay: Only 400 persons in contact camp; if removal of contacts properly worked the number ought to have been 2,000, 10,953.
Bombay: Only one contact secured to four cases of plague, 4031.
Cutch Mandvi: Seven or eight segregated per case, 493.

Segregation of:

Contacts should be kept in a camp by themselves if possible, 23,346.

See Camps.
,, Segregation.

COPPER SULPHATE:

Result of tests with metallic salts, II. 6.

CORDONS:

Cordon arrangements and details of:

Daman and British India: intercourse between, periods in which stopped and permitted, 15,964–5.
Daman: Cordon removed in November 1898, 16,609.
Daman: Frequenting of Portuguese liquor shops not forbidden to British subjects when plague discovered in Daman, 15,967–8.
Daman: From April 1897 to October 1898, inter-communication permitted with passes, and of 2768 persons detained four developed plague, 15,965, 15,993–4, 16,609.
Daman Frontier: Description of cordon operations, 15,979.
Daman: One hundred and thirty-nine persons arrested for attempts to break the cordon, 15,989.
Daman: Plague did not spread, even before cordon put on, as villagers themselves refused admittance to suspicious persons, 15,964, 16,000.
Daman: Salt cordon increased during plague, 15,969.
Daman: Three lines of protection on British side of frontier: salt cordon, police, and villagers, 15,977.
Hubli: Chawls cut off by cordon of armed police, 1581–4.
Kaira: Strict measures to prevent communication between Kaira district and the Gaikwari territories by the Mahi river, 14,015.
Karachi: Advantageous for imposition of cordon, shut in by the desert and the sea, 11,297.
Karachi: Cordon at, 11,240, 11,297.
Karachi: Malir camp surrounded by thorn fence and guarded by police and sepoys, 12,441–45.
Karachi: Nine plague cases stopped by the cordon, 12,433–4.
Khandraoni: Cordon broken by one person, 9669.
Khandraoni: Villagers placed under a cordon, 244 soldiers for 435 people, 9648, 9669, 9693–4.
Kotri: Cordon regulations at, 12,605–19–37.
Kotri: Cordon placed three days after second outbreak, 12,603.
Kotri: No one could get away without a pass, 12,680.
Kotri: Railway quarter not included in cordon, 12,620.
Palanpur State: No cordon around the camps, 13,164.

CORDONS—*cont.*

Panjab: Cordons placed round village area to prevent communication of people of infected village with outsiders, and round village site to prevent visits to infected houses, 10,057.
Panjab: Cordons and evacuation the measures natives most dislike, 10,310.
Panjab: System of police cordons, 10,057–63.
Poona: Cordon arrangements, 21,299–300.
Rohri: Cordoned against plague from Sukkur, 12,923.
Rohri: Cordoned to protect Panjab, but infection passed through the cordon, 12,046, 12,078, 12,083.
Sholapur: Cordon arrangements, 20,229–30.

Cordons efficient:

Bilron: Cordoning of the area successful, but the village re-infected from outside, 10,741.
Cordon at Mahi river was sufficient to stop the spread of plague until it was relaxed, 14,193–201.
Cordons, effective measures for preventing the spread of disease outside, 9737.
Cordon of police has a great moral effect on the people, 10,061.
Cutch Mandvi: Cordon of 20 men sufficient for a village in Cutch, with 900 inhabitants, 13,584–9, 13,649–53.
Daman: Registration accurate because of cordon in, 160.
Karachi: Few cases escaped the cordon, 18,140.
Kotri: Only two individuals got through the cordon, 12,621, 12,633.
Panjab: Want of cordons around the villages cause of plague in the Panjab camps, 10,758.
Sirohi: Cordons round infected villages, plague did not spread out, 9737, 9901.
Umra: Cordon effective in preventing spread of plague to Surat, 2051–2.

Cordons inefficient:

Cordon of eight to the mile insufficient, 10,779.
Cordons round infected villages should in all cases be combined with inspection, 10,637.
Cutch Mandvi: Cordons no good in Cutch, only tried in two cases, 13,501–3.
Daman: Notwithstanding cordon, people escaped, 16,446.
Hubli: Cordon not efficient through slackness of police, 1584.
Hubli: Cordon of 60 native police insufficient to keep people out of evacuated chawl, 20,149.
Hubli: First cases attributed to default of the police and clandestine meetings with people belonging to the chawls when they were cordoned, 2407, 2436, 20,151.
In practice quite impossible to maintain the cordon in an efficient manner, 8782, 8922.
Mahi river cordon failed to keep out plague, 14,055.
Molagavelli: Police guard inefficient at, 4442.
N.W.P.: Position of Kankhal very favourable for cordon, but cordon ineffective, 9213, 9366.
Panjab: Cordons not strictly effective, 10,528–9.
Panjab: Effectiveness of cordon decreases in proportion to the extent of area, 10,316.
Panjab: Facility for passing the cordon by bribing the police, 10,242.
Panjab: Only eight men to the mile in cordons round village areas, and cordons not strictly effective, but moral effect good, 10,058–67, 10,242.
Poona: Not the least difficulty in evading the cordon, 21,328.
Sholapur: Cordons drawn round the Sadr Bazar and town to confine the plague a complete failure; precautionary measures frustrated by bribing the police, 20,230, 20,237–8.

CORPSE BEARERS:

Corpse bearing is not dangerous, 19,962.
Instance of plague among corpse bearers in Bombay, 19,036.

CORPSE BEARERS—*cont.*

No cases of plague from corpse bearing in Poona, 21,566–9.

People kept plague alive in camp at Surat by going into the town and acting as corpse bearers, 24,422.

See Funerals.

CORPSE INSPECTION:

Arranged under the following subheads:

Adoption at.

Agency by which carried out.

Complaints made in Places where carried out.

Efficacy of Corpse Inspection in Classification of Causes of Death.

Efficacy of Corpse Inspection if Females exempted.

Efficacy of Corpse Inspection in Identification of Plague.

Efficacy of Corpse Inspection in detecting Pneumonic Plague.

Efficiency of Corpse Inspection with reference to the Place of Inspection.

Feelings of the Natives regarding Corpses.

Feelings of the Natives regarding Corpse Inspection generally.

Feelings of the Natives regarding Corpse Inspection of Females.

Opinions regarding Corpse Inspection as a Measure.

Adoption at:

Ahmedabad: Corpses seen after death from plague, 13,945.

Ankleshwar: Carried out in 1898 at, by three medical officers sent from Bombay, whose duty it was to inspect the corpses, which should be disposed of only on death certificates or after corpse inspection, 14,264–7, 14,280–2, 14,295–6.

Bangalore Civil and Military Station: Carried out in, without objection or opposition, 2709–10, 2712, 25,101–3, 25,105.

Bangalore City and Mysore City: Carried out in, without disturbance, 25,101–3, 25,105.

Baroda City: No corpse inspection at, between first and second outbreak, 14,592–3.

Baroda State villages: Carried out in, but requires great tact, 14,665–6.

Belgaum district villages, none in, 23,019.

Bhagda, corpses seen at, 16,199–200.

Bombay: At cemeteries, no corpse inspection in end of 1898, 1122.

Bombay: At cemeteries, medical officers have orders not to examine bodies under any conditions, 25,654–5.

Bombay: Bodies examined at cemeteries in suspicious cases, till this excited opposition, when examination given up, 1119–21.

Bombay, in, no system of examination of dead in end of 1898, 1129.

Bulsar: In absence of death certificate all bodies examined, 16,169–72.

Calcutta: In many cases when suspicious case heard of, inspection of body allowed by people of the house, 6514.

Calcutta: No system of corpse inspection in, 6513, 6515.

Cutch Mandvi: Carried out at, after January 1898, except when death certificate produced, 13,435, 13,552.

Hubli: Bodies examined by Dr. Cardoz, who was occasionally, but not regularly, employed on the duty, 2473, 3136–7, 19,840.

Hubli: Bodies examined with post-mortem in doubtful cases, 3076–8, I. 400 (XVIII.), 20,007.

Hyderabad, Sind: Carried out in, without objection, 18,132–3.

Hyderabad State: Carried out in, 5928–9.

Kaira district: No regular corpse inspection in, as most plague cases died in hospital, but corpses, male and female, examined if necessary, 14,083.

Karachi: None at, before or at beginning of first outbreak, 12,987.

Karachi: Carried out between the first and second epidemics, 11,183.

Karachi: At end of 1898 modified corpse inspection carried out, being dispensed with for children under two, and in cases where death properly certificated, 11,384–90, 12,777–8, 12,790.

Karachi: All corpses seen for which death certificate not forthcoming, 11,394.

Karachi: Compulsory in the voluntary camps at, for every person who had not been under treatment, 11,937.

CORPSE INSPECTION—*cont.*

Karachi: Corpse inspection not necessarily resorted to in case of Khojas, 13,259.

Karad: Corpse inspection resorted to, 21,064.

Kotri: All corpses of children inspected at, 12,688.

Kotri: Carried out in, without objection, 18,132–3.

Kotri: Was carried out at, in first epidemic, being discontinued in May 1897, but re-instituted in September, and continued throughout second epidemic, 12,554–5, 12,681–6, 12,734–5.

Mysore: Corpses regularly inspected without disturbance, 25,101–5.

North-Western Provinces: Both Hindus and Muhammadans examined; the latter did not resent it more than the former, 9236–8.

North-Western Provinces: Carried out in, those who would not submit to it being treated as infected, 9191, 9197–9.

Palanpur: Carried out in, 13,166.

Poona City, Carried out in, 21,355–83, 21,416–50, 21,774–8.

Poona City: Corpse of every person who dies in, inspected, 21,486.

Poona City: Diagnosis made by, plus inquiries into history of cases, 21,422.

Poona City: Done at the house in Poona, not at cemeteries, 19,916–8.

Poona City: Statistics relating to, in, 21,416, 21,788–94, 21,859–64.

Poona Cantonment: Carried out before removal of body, 21,261, 21,299.

Porbandar: Of all Hindus and male Muhammadans carried out at, 13,730.

Punjab: Carried out and not objected to in Banga and other villages, 10,253.

Rohri: Carried out in, 12,026.

Satara Town: Carried out in, without objection, 22,481–6.

Satara district villages: Carried out in, 22,629, 22,747.

Sholapur: Carried out at, without opposition, males and females, Muhammadans, Hindus, and even pardah nashin women, 23,879–86.

Sirohi: Not resorted to in, 9778, 9899.

Surat: Corpses examined at the instance of the Vigilance Committee, 15,854.

Umreth: Bodies seen at, 14,024–5.

Agency by which carried out:

Ankleshwar: Done in, by Hospital Assistant Cooper, 14,265–6.

Bhagda: Corpses seen by Hospital Assistant, 16,199.

Bhiwandi: Carried out in, by hospital assistants, 22,185–8.

Bhiwandi: Memons at, object to corpse inspection of their women by hospital assistants without presence of Europeans, 22,189.

Bombay: Hindus and Mussalmans willing to have corpses examined by Europeans, but not by Native doctors of another faith, 17,968.

Bulsar: Carried out in, by hospital assistants, 16,169–171.

Calcutta: Objection to would depend on manner in which carried out; with Brahman doctors Hindus would not object to corpse inspection of males, 6606, 6682.

Cutch Mandvi: Done by Native doctors and hospital assistants, and certificates liable to suspicion, U., 474.

Hubli: Done by Assistant Surgeons and Hospital Assistants, 3077.

Kaira district: Done by Hospital Assistants, 14,083.

Kotri: Done in, by Assistant Surgeon Macmullen and by hospital assistants, 12,700, 12,735.

North-Western Provinces: To meet Native views, carried out by assistant surgeons accompanied by Native medical practitioners; if they disagreed, Commissioned Medical Officer called in, 9200.

Poona City: Arrangements for carrying out in, 21,423–442, 21,462–4.

Rohri: Done in, by hospital assistants, 12,026.

Satara: Carried out at, by Hospital Assistants, 22,482, 22,575.

Satara: If done only by European doctors, could be done only at headquarters, as no staff available elsewhere, 22,102.

Umreth: Bodies seen by Hospital Assistant, 14,024–5.

CORPSE INSPECTION—*cont.*

Complaints made in Places where carried out:

Caste, objection to inspection of a Brahman in Poona City, except by Brahman doctor, 21,373.
„ objection to examination in case of a fakir in Pooma City; body afterwards examined by Brahman doctor, 21,373, 21,825.
„ in examination sometimes caused great annoyance in Poona City, 21,549.
„ two or three complaints in Poona City that laying out of body delayed, 21,569–71.
Delay in objections have been made in Poona City on account of delay in disposing of body, 21,869–71.
„ objection to, in the North-Western Provinces on ground that it delayed disposal of body, 9200.
In Poona not objected to, except on two or three occasions, 19,920–1, 19,934.
Sex, only one objection in Poona City to examination of female corpse, 21,375.
„ one objection in Poona City regarding Muhammadan female, whose body was finally inspected, 21,825.
„ only one objection in Sholapur, not serious, female doctor being asked for, 23,884.

Efficacy of Corpse Inspection in Classification of Causes of Death:

Allows of classification only into "certainly plague," "certainly not plague" and "suspicious," 21,902-5.
In Poona City deaths classified as plague only when bubo found; character of deaths classified as suspicious, houses in which they occurred being disinfected, 21,906-13.

Efficacy of Corpse Inspection if Females exempted:

Useless unless bodies of women examined, 3810.
Would give good idea of existence of plague if most males examined, 6606, 9239.

Efficacy of Corpse Inspection in Identification of Plague:

Best means for early detection of epidemic, 9521–2.
Disease cannot always be diagnosed after death 11,366.
Every case of plague could be discovered by corpse inspection, by existence of buboes or œdema, 9620.
Found useful in Poona City for the identification of plague cases when done by European doctors, 10,979–82.
In many cases impossible to detect cases of plague by, 21,958.
In Poona City 85 per cent. of deaths due to bubonic plague, which can be detected by corpse inspection, 21,865.
In Poona City 106 cases of plague, mostly bubonic, discovered by corpse inspection among 3,035 corpses examined, 21,376–9, 21,444–5, 21,449, 21,477–84.
Instances in which the inspection of corpses actually carried out at Karachi has failed to detect presence of plague, 12,780–8.
More useful than sick visitation, only one case of plague discovered by latter in Poona City to four discovered by corpse inspection, 21,381–2.
No example met with of subsidence of bubo in bubonic plague just before or after death, 21,443, 21,866.
Suspicious cases; general look of body and retention of warmth assists detection by corpse inspection, 21,365–6.
Useful but not reliable for the detection of every case of plague, 12,779.
Useless where bubo is not pronounced, and in puerperal cases, 11,391.
Would help in determining whether there was plague or not, 6605.
Would not materially assist in finding plague cases in Bombay, 17,887.

Efficacy of Corpse Inspection in detecting Pneumonic Plague:

Pneumonic plague, after death, could not be detected by, 1135, 3808, 11,393, 14,285, 18,134, 26,744.
Pneumonic plague can, generally speaking, be detected by medical examination and inquiry, but not certainly, 21,732–8.

CORPSE INSPECTION—*cont.*

Pneumonic plague cannot be diagnosed in case of dead body with certainty without bacteriological examination, 20,017–8.
Pneumonic plague, could be discovered by corpse inspection by existence of œdema, 9618–20.
Pneumonic plague, could not be absolutely certain about, by corpse inspection, 19,922.
Pneumonic plague, difficult to diagnose by, 21,465–8.
Pneumonic plague, not much value in cases of, without post-mortem, 8812–3, 9434–5.
Pneumonic plague, not sufficient to ascertain whether a person has died of pneumonic plague without history which is inquired into, 9240–2.
Pneumonic plague, of doubtful use in, and would give uncertain results, but indications might be gained from dribbling saliva, 6686–8.
Useless for discovery of plague, as pneumonic form of the disease cannot be found out by it, 26,799.

Efficiency of Corpse Inspection with reference to the Place of Inspection:

Advantage of showing where plague has occurred, not realised if examination takes place at cemeteries, &c., 8815–6.
Better done in house where death occurred, as, if death due to plague, information as to locality of disease obtained, 19,919.
Bodies in some cases removed from houses in which they were living, 8317.
No corpse could be surreptitiously buried in Poona City in beginning of 1899, 21,570-2.

Feelings of the Natives regarding Corpses:

Against Hindu and Muhammadan religions to touch a corpse after death, 12,521.
Corpses not to be touched after the death ceremonies performed, 26,745.
Dead not regarded with same respect as living, no objection to body being touched, 3805–7.
Objection to body being seen or touched, 10,987.
People have great horror of their dead being examined after death, 13,435, 13,552.
People often quite callous as to what is done with their sick and dead, 22,749.
Unnecessary to bare body for corpse inspection, 3307.

Feelings of the Natives regarding Corpse Inspection generally:

Bangalore Civil and Military Station: Muhammadans object to their houses being entered for, 2711.
Bhiwandi: Would have been difficulty about in, for Muhammadan females, and could not have been carried out without presence of Europeans, 22,193–4.
Bombay: Anything more than summary inspection of body would be impossible, and resented on religious grounds, 1136.
Bombay: At the cemeteries not objected to in, 17,745.
Bombay: Corpses sometimes examined at cemetery, till opposition caused by it led to abandonment of such examination, 1120.
Bombay: Done in, without difficulty, but Natives would object to it in most cases, especially if done by young medical men, 17,967, 17,970.
Bombay: Would arouse much opposition, 25,619.
Bombay: Would have a very disturbing effect in, 17,887.
Calcutta: Allowed by people of houses in several cases, 6514.
Calcutta: Difficult, and would require delicate handling, 6682, 6684–5.
Calcutta: Muhammadans would not object to, for males, if doctors good class and right sect, 6683.
Calcutta: Some Natives rather pressed adoption of, as a measure, 6685.
Calcutta: Would be objected to, even for males by Hindus and Muhammadans, who would yield neither to it nor to rule requiring death certificate in lieu, 7548.
Cutch Mandvi: No objection to, at all among Muhammadans or others, 27,174–6.
Karachi: Hateful to the people, because against Hindu and Muhammadan religions to touch a corpse after death, 12,521.

Corpse Inspection—*cont.*

Karachi: Muhammadans in first outbreak got accustomed to, but before second outbreak asked for services of lady doctor, for which they paid fees, 3803.
Karachi: No great objection to, 3802.
Many classes to whose feelings corpse inspection is repugnant, 11,284.
Muhammadans have submitted to it in certain parts only because they saw the hopelessness of opposition, 26,811.
Muhammadans would be prepared to have their female corpses examined in preference to undergoing segregation, 9440–2.
Muhammadans would object specially, but corpse inspection is objectionable to all people, 17,886.
Northern India: It would be dangerous to make corpse inspection compulsory in the North-Western Provinces and the Punjab, and not worth the opposition it would give rise to, 26,744, 26,801.
North-Western Provinces, disturbances and riots at Jawalapur, due to dislike of corpse inspection and to other causes, 9192–6.
North-Western Provinces: More difficult in Jawalapur than in Kankhal and Hardwar, 9243–4.
North-Western Provinces: Natives prefer corpse inspection, even of women, to segregation, 9439.
North-Western Provinces: Not liked in, but carried out without opposition if not insisted on where death properly certified, 8808–10.
Panjab: Not objected to in villages, 10,253.
Poona: No objection to in, where Muhammadans not strong, 10,883, 10,885.
Poona: No objection to, 21,824.
Poona: Not opposed in, because the Natives were utterly disheartened, 26,744, 26,775–7.
Rajputana: Not possible among the Muhammadans in, especially in large towns, 9780.
Satara: Natives would have no objection to examination of corpses by European doctors, 22,098.
Satara: Hindus would not object to examination by Muhammadans and *vice versâ*, 22,099–100.
Satara: No difficulty about corpse inspection at, Muhammadans being a small and inconsiderable portion of the population, 22,481–6.
Satara district villages: Corpse inspection offensive to the feelings of the people in, 22,629–30.
Satara district villages: People as a rule show both male and female corpses freely, 22,748–9.
Sholapur: No opposition, 23,879–86.
Sind: Not liked anywhere in, 3802–6.
Sind: No very violent opposition to in, 11,284.
Sind: Muhammadans would probably object to examination by Hindus, 22,099–100.

Feelings of the Natives regarding Corpse Inspection of Females:

Bangalore Civil and Military Station: Female bodies examined by females, 2711, 25,104.
Belgaum district villages: Would be offensive and impossible in case of pardah women, 23,020–4,
Bhiwandi: Difficulty probable at, in the case of females, 22,193–4.
Bhiwandi: Memons at, object to females being examined by Natives in absence of Europeans, 22,189.
Bombay: Muhammadans might resent examination of females, but have not done so, 17,969.
Calcutta: Better left alone as regards females; even by female doctors, would not be liked, 6606–7.
Hyderabad Sind: Female corpses inspected by lady doctor, 18,134.
Hyderabad State: Some Muhammadans object in case of females, but female bodies not examined, 5930–1.
Karachi: Bodies of women examined, 3810.
Karachi: Muhammadan females, bodies of, examined by ordinary doctors, and later by female doctors, 3804.
Mysore: Women examined by women, 25,104.
North-Western Provinces: Carried out in case of women, 9433.
North-Western Provinces: Females examined by men, but inspection of female corpses not insisted on to the same extent as that of males, 9202–4, 9239.
North-Western Provinces, Hardwar and Jawalapur: Muhammadans objected to in case of females, but no great objection, 9265–8.
Objection anticipated, especially in case of females, 26,745.
Poona Cantonment: Done in houses in, without objection, regarding Muhammadan women or others, 21,260–2.
Poona City: No objection particularly to inspection of female corpses, 21,372.
Porbandar: Only during the height of the epidemic insisted on for female Muhammadans, 13,730.
Satara: Muhammadan females have been examined by doctors, though the examination usually done by female doctors, 22,101.
Satara district villages: Of females not offensive to feelings of people, except in pardah families, 22,748–9.
Sholapur: Examined at, without opposition, 23,882–4.
Sholapur: No objection to examination of groin of female bodies, 23,973–4.
Umreth: Female bodies seen by Hospital Assistant, 14,025.
Utterly repugnant to Muhammadans and Hindus, especially in the case of females, 26,810.

Opinions regarding Corpse Inspection as a Measure:

Bombay: By slow process corpse inspection in, at houses might be ultimately introduced, and would be advantageous, 25,620–1.
Bombay: Corpse inspection would undoubtedly give more complete information than system of inquiry in force in Bombay, but would arouse much opposition, 25,618–9.
Bombay: Not recommended in, where Muhammadans too strong, 10,983–5.
Bombay: Probably not applicable to, 19,924–5.
Bombay: Recommended in, at cemeteries, where it is probable that correct addresses of deceased would be obtained, 17,748–52.
Cardinal measure before sanitation and preventive measures, but the difficulty is how to do it, 26,738.
Death registration without corpse inspection would be valuable, 26,748.
Desirable in places where considered feasible by authorities, 9438.
Difficult to make it penal to move or dispose of corpses before examination, 26,737–8.
Most important in large towns at the beginning of an epidemic to ascertain presence of plague; unnecessary after plague has spread, 9247.
Most valuable agency there can be employed, combined with bacteriological examination of suspicious cases, 21,929.
Necessary for early detection of first cases, 9430–1.
Necessary measure, 8810, 8815.
Necessary, but should be carried out with as little inconvenience to people as possible, 21,549–50.
Next best measure to notification of diseases, 19,923.
Northern India: In large towns, would require great tact, but could be arranged at beginning of epidemic with co-operation of Native leaders, who would be anxious to trace and suppress first cases; impossible after spread of plague, 9247–51.
Not recommended, 26,743, 26,747, 26,774, 26,795–7.
Not recommended that Health Officer should have the power of corpse inspection if, under a system of death registration, he doubted the correctness of a certificate, 26,773, 26,804–9.
Option may be offered of submitting to or being treated as infected, 8814.
Possible to be carried out in most communities, 9432.
Unnecessary in Karachi, owing to efficiency of system of supervision of mortality, 11,284.
Unnecessary, as plague cannot always be diagnosed by, after death, 11,366.

CORPSE INSPECTION—*cont.*
Unnecessary if mortality carefully watched, when, if suspicion aroused, it can be resorted to, 11,285.
Very valuable, 11,284.

COTTON:
See Merchandise.

COW-DUNG:
Identification of Bacillus of Plague in:
No method for identifying the microbe in cow-dung, 8537.
See Isolation of plague bacillus.
Life of Bacillus of Plague in:
In laboratory experiments the plague bacillus lived several months in sterile cow-dung, 18,877.
In unsterilised cow-dung the microbe did not live more than six days, 18,880.
See Perchloride of Mercury: *action on the bacillus of plague.*
,, Permanganate of potash.

CULTURES OF BACILLUS OF PLAGUE:
Aeration of:
Addition of ghee to assist aeration of cultures, 27.
Characteristics:
Characters of bacillus not constant in cultures, very varying, and different from characters of bacillus obtained from the blood of animals, which are constant, 26,123.
Size varies considerably in the different growths, 26,402.
Specular appearance of colonies on agar, not an important characteristic, 8667, II. 4.
Stickiness a very variable attribute in the microbe of plague, 8669.
Tangled skeins, in bouillon and gelatine the bacilli form long, 8719.
Thready colonies produced on agar plates, 27,320.
Typical appearance of plague cultures, 3654.
Isolation of Plague Bacillus in Cultures:
Method for isolating the plague microbe in cultures, 8594.
See Isolation of bacillus of plague.
Media of Cultivation:
Agar: In cultures with salt agar involution forms will develop in 24 hours if kept in the incubator, 8717.
Albumose: Grows better in albumose than in real peptone, 17,387.
Bouillon: Characteristic growth of the microbe of bubonic plague in bouillon II. 4, 8719.
Gelatine: Characteristic growth of the microbe in, II. 4, 8719.
Peptone: Grows better in albumose than in real peptone, 17,387.
Plantain: Grows on sterilised plantain, 26,428.
Warden's broth: Bacillus of plague cultivated in Warden's broth and ghee for Haffkine's prophylactic, 27.
Post-mortem:
Method of making post-mortem cultures, 8393.
Temperature for:
Favourable cultivation temperature for bacillus of plague, 80–90 F., 99.
Plague virus grows fastest at a temperature of 37° C., 26,342.
See Bacteriological characteristics of bacillus of plague.
,, Coli Bacterium.

DAMAN:
Inoculation in, with Mr. Haffkine's Prophylactic:
Daman statistics, correctness of, 160.
Figures checked by Mr. Damaun Wala and his servants: effects of inoculation in each of three years, 25,429–41.
Increase of plague among the uninoculated at Daman, 18,701–7.
Inoculations among the Parsees, 16,787–93.
Inoculations at Daman, 25,417–26.
Inoculations done in 1897 and 1898: House inspections showed that the uninoculated got plague while the inoculated escaped, 16,361–4.
Inoculations introduced in March 1897, 16,405–7.
Inoculations in Upper Daman only, 27,207.
Inoculation of all the inhabitants of the Fort, Upper Daman, including about 140 soldiers, and though rats died there was no plague among men, evacuation being resorted to in addition to inoculation, 16,448–58, 16,476.
Inoculations performed at Daman, summary of results, 52–60, 72.
Investigation sheets, manner of preparing and checking, 27,211–3, 27,284–6, 27,297, 27,301.
Method of checking plague occurrences among the inoculated; in 1897, on account of the panic and confusion, the statistics are quite unreliable, 16,744–9.
Method of collecting and checking particulars for the preparation of investigation sheets and the Joint Report on Inoculations, 16,862–77.
Method of inquiry into the figures relating to Daman, 27,189–204, 27,274–9.
Mortality rates among the inoculated and the uninoculated at Daman, 27,280–302.
No death from cause other than plague among the inoculated in Daman, 25,446.
Report on plague in Lower Daman, and effect of inoculation there, by Mr. Haffkine and Surgeon-Major Lyons, I. 305–330.
Upper Daman: In 1898 333 inoculations, with 48 cases and 18 deaths among the inoculated, 16,460–3, 16,604–5, 16,611.
Watch kept upon the inoculated, to observe effects, 25,427–8.
Statistics relating to:
Concealment of cases common, so that in April 1897 the authorities took steps to ascertain the numbers of dead by special inquiries at burial and burning places, 16,415–9.
First epidemic in 1897, February to June, Lower Daman only affected, 2,000 deaths, I. 306, 16,371–2, 16,385.
In epidemic of 1898, 1,318 attacks and 1,224 deaths, 16,511.
Lower Daman: Out of a population of 7000, 3,000 died of plague, 15,959.
Lower Daman: Population 7,000, 16,846, I. 305.
Plague at first worst among Muhammadans, and spread to Machis, 16,351.
Plague spread from Machis to Banniahs, and thence to Muhammadans, 15,959.
Population, number of deaths, and extent of emigration from Daman estimated by guess-work, 27,214–42.
Sixty-eight per cent. of cases plague mortality, I. 382.
System of death registration in force in 1897–8, 16,640–2.
Upper Daman: 1,000 deaths from plague during the second outbreak, 15,959.
Upper Daman: No plague in 1897, 16,430.
Upper Daman: Population, 5,400, 16,345, 16,464, I. 305, 16,438.

DAMP:
Bombay, Byculla Jail: Observations on the effect of moisture and dryness on plague in, 17,113.
Bombay: In 1896, a fortnight after the heavy rainfall, the shady streets were still damp, 898.
Bombay: Water supply had to be cut off from houses in Mandvi to prevent their dampness, 916.
Dryness of inhabited places the best prophylactic measure, III. 9.
Life of Bacillus of Plague in:
Flourishes most luxuriantly when the air is moist, 18,638.
Microbe establishes itself mostly in the presence of damp, dirt, and darkness, 9683.
Vitality of the germ is diminished by the sun and increased by damp, 17,031.
See Rains.
,, Sanitary conditions
,, Subsoil water.
,, Water.

DEATH CERTIFICATE.

See Registration of death.

DEER:

Died of plague at Bangalore, 3601.

DESICCATION:

Effects on Bacillus of Plague:

Bacillus found to survive five days desiccation in hydrogen, II. 8.
Bacillus somewhat resistant to desiccation, II. 13.
Bacillus desiccated in glass rods in air lived 48 hours, 18,886.
Bacillus shown by experiments to survive four days ordinary drying, 26,344–5.
Bombay, Byculla Jail: Observations on the effect of dryness and moisture on plague in, 17,113.
Desiccation with calcium chloride kills bacillus of plague in 18 hours, 26,346.
Disinfection of crews kit and clothes by exposure to sun and air, 738, 814.
Drying and ventilation the best methods of disinfecting, 33,662.

See Air and Light.
,, Sun.
,, Ventilation.
,, Hot weather.

DETECTIVES.

DIAGNOSIS OF PLAGUE:

Difficulty of:

Bacteriological examination the only means of certifying plague cases, 20,014, 22,352.
Easy when several cases occur together, 6905.
Special points in diagnosis, I. 352.
Very difficult, 1016.

Of Plague and other Diseases:

Alcoholic poisoning: Plague mistaken for alcoholic poisoning, I. 382.
Glandular fever: Seeing patient once would not show whether plague or glandular fever, 6987.
Glandular fever: Cases in Bombay mistaken for plague, 22,351.
Malaria: Distinctive symptoms between plague and malaria, I. 381.
Relapsing fever: Doubt whether cases plague or relapsing fever, 24,184.
Relapsing fever: How to distinguish plague from malaria and relapsing fever, I. 381.
Relapsing fever: Many cases sent to plague hospitals proved to be of relapsing fever and other diseases, 25,732.
Small-pox: Epidemic of small-pox and plague which developed together in three villages of the Satara district rendered diagnosis of plague at first doubtful, 21,657.
Typhus: Difference between plague and typhus fever, I. 381.

Of Types of Plague:

Bubonic plague: Bubo not alone sufficient basis for plague diagnosis, 7530.
Bubonic plague: Difficulties of diagnosing plague during life, even when glands are enlarged, 20,027, 20,032.
Non-bubonic plague: Most men now engaged in plague work are absolutely incapable of diagnosing case of septicæmic plague, 20,135.
Non-bubonic plague: Native practitioners fail to recognise plague, especially septicæmic or pneumonic, 1638.
Non-bubonic plague: Pneumonic and septicæmic cases may easily escape detection if attention is only directed to the evidence of buboes, 13,915.
Non-bubonic plague: Position of the corpse an indication in the absence of enlarged glands, 18,556.
Pestis minor: Of mild bubonic cases, difficult, 6907.

DHERS:

Dhers, although impure people, not very subject to plague, 5478.
Plague spread by the Dhers, 15,337.

DHOBIS:

Bombay: Statistics of cases among dhobis up to December 1896, I. 392, 3.
Bombay: Statistics regarding dhobis admitted to the Arthur Road Hospital, III. 466.
Calcutta: No plague among dhobis, 7665–7.
Karachi: An outbreak, 5 cases, in a group of 70 dhobis, 11,314.
Satara: Cases among dhobis, 21,269.

DIRT:

Life of Bacillus of Plague in:

Dies in dirt, 1003.
Establishes itself mostly in dirt, 9683.
Incapable of existing in dirt, 1003–4.
Virulence of bacillus of plague increased by filth, 18,635.

Opinions that Plague a Filth Disease:

Open air and cleanliness the best preventives against plague, 17,711.
Plague bacillus establishes itself and ourishes in dirt, 9683.
Plague is a disease of filth and dirt, 7836.
Plague a filth disease, and will most likely attack persons living under insanitary conditions, 12,018.
Plague a manifestation of septicæmia by a special virus of filth disease, 25,249.

Opinions that Plague not a Filth Disease:

Filth *per se* has little influence; Byculla Jail beautifully clean, but most virulent outbreak, I. 378.
Kumaun: People very dirty; they hold that dirt is a preventive against Mahamari by closing the pores of the skin, 6159, 8832.
Plague not due to dirt, 1003.
Plague not a filth disease, 16,524.
Very dirty classes, such as Dhers and Mangs, not very liable to plague, 5478.

See Sanitary conditions.
,, Scavengers.

DISCOVERY OF BACILLUS OF PLAGUE.

See Isolation of plague bacillus.

DISCOVERY OF PLAGUE:

Early discovery of Cases, importance of:

Early detection the best means of preventing spread of disease, 9518.
Early discovery of plague cases most important, 19,479.
Early information of plague cases, &c. most important measure in dealing with plague, 12,052, 16,967–71.
Early information and proper measures prevented the disease for a long time from becoming local in Hyderabad Sind, 18,897.
Early intimation the most important factor, 17,669.
Evacuation would become unnecessary if information could be obtained early enough to limit the zone of infection, 21,711.
Evacuation unnecessary if early notification be given, 16,026.
If plague discovered early, ordinary measures stamp out the disease, 14,062.
Natives should be employed as voluntary agents for obtaining early information 26,730.
Partial evacuation sufficient if early intimation of first case obtained, 13,797.
Plague accidentally discovered at Backergunge, 7426.
Report of villages where early discovery of cases and suitable measures at once stopped the disease, 14,062.
The more perfect the organisation for obtaining early information the better results may be expected from plague measures, 21,708.

DISCOVERY OF PLAGUE—*cont.*

DISINFECTION:

Attitude of the People towards

Bangalore: Great opposition to disinfection, 2719.
Calcutta: Disinfection strongly disliked, 7520.
Calcutta: Disinfection carried out in Cross Street with difficulty by personal influence of officers, 7521.
Calcutta: Chemical disinfection supposed to injure the health by the residents of the Bara Bazar, and therefore resisted and hindered, 7520.
Calcutta: Natives begin to disinfect their houses of their own accord, 7661.
Calcutta: Objection to segregation but not to disinfection, 6545.
Calcutta: People might be persuaded to leave bustees for disinfection for three hours if camps were provided, 7718–20.
Cause of irritation in rural districts, 19,515.
Dharwar: People have no belief in disinfection, but apply for it as a means to return to their houses, 23,776.
Hubli: When disinfection of houses was gratuitous, people used to bribe the "coolies" to mark houses as disinfected without disinfecting them, 23,366, 23,399.
Hubli: People at a late stage in the epidemic paid for disinfection of houses, and they resorted to disinfection through rivalry to see who would spend most on it, 23,454.
Karachi: Opposition to disinfection, 11,651.
Natives object to disinfection by chemicals, 9740, 9823.
Native States: Great difficulties in disinfecting villages, 9739.
Objectionable from the Indian's point of view, 16,232.
Opinion that the system of drenching the houses whilst people were in them to a certain extent responsible for the epidemic, 16,137.
People not yet convinced of the usefulness of disinfection of houses, 14,763.
Surat: Chemical disinfection led to concealment of cases, 16,137.

Difficulties in carrying out Disinfection:

Bombay: At beginning of epidemic no apparatus, no stoves, no special disinfecting staff, 1147–50.
Bombay: Disinfection very imperfectly carried out in Bombay, 25,650.

DISINFECTION—*cont.*

Bombay: Unsatisfactorily carried out in, owing to want of supervision, 416.
Calcutta: Almost impossible in bustee houses, 7689–90.
Calcutta: Disinfection almost impossible in the insanitary parts of the town, 7519.
Calcutta: The construction of bustee houses is the great impediment to their thorough disinfection, 7709.
Chemicals useless in mufassil towns on account of the construction of the houses, 24,316.
Cleansing of the evacuated houses by the natives themselves a cause of renewed infection, 23,174.
Coolies cannot be taught to do their work efficiently, 16,987, 21,095–7.
Coolies careless: impossible to be sure of efficient disinfection of houses, 11,273, 24,342.
Difficult in hospital through patients spitting anywhere, 7085.
Disinfection of houses very little practicable, 23,187.
Disinfection of houses in India useless on account of the rats, which are not affected, and keep up the infection, 8578, 11,460–2, 22,864.
Hubli: The natives were made to pay the costs of disinfection with consequence that they took care the work was not shirked, 23,368.
Impossible to reach every crevice in houses with disinfecting solution, 20,161.
In native houses very difficult. So many crannies, 7856, 15,181, 24,342.
Of surface in houses at Karachi useless on account of their structure, 11,461.
Surat: Disinfection unsatisfactorily done 24,450.

Houses: Extent of Disinfection:

Ankleshwar: Only those streets disinfected where plague cases had been found, 14,234.
Baroda: Perchloride of mercury used for all houses in which any death had occurred. The others thoroughly cleaned, whitewashed, and opened for ventilation, 14,631.
Belgaum: Disinfection of houses and burial parties the only plague measures employed, 22,807.
Belgaum: No attempts possible to disinfect other than infected houses, 22,830.
Bombay: Houses at first, though not later, whitewashed in advance of the probable line of plague, 1214.
Bombay: In infected houses, only the room of the patient and the two adjoining rooms disinfected, 25,640.
Calcutta: Only the room of the patient disinfected, 6591.
Dharwar: Disinfection of houses in villages impossible with staff available, 2145–6.
Disinfection should not be confined to plague-infected houses, 14,439.
Karachi: Disinfection of all plague-infected houses, 12,789.
Malegaon: Every house disinfected, 18,080.
Mysore villages: No disinfection done, 3324.
N.W.P.: Whole town at Hardwar, Kankhal, and Jawalapur systematically disinfected, 9045–8, 9090, 9115, 9175.
Poona, Sadashiv Pet: Every house disinfected, 21,589.
Roof ought to be disinfected as well as rest of rooms, 7857.
Roofs should be disinfected as well as walls and floors, 20,163.
Satara: Restricted to infected houses, 22,298.
Sholapur: No disinfectants used in the villages round, 24,037.
Whole of wall might well be disinfected, 5785.

Imported Cases and Disinfection:

Disinfection without evacuation recommended for imported cases, 22,892.

Instances in which no Cases followed House Disinfection:

Ankleshwar: No instance known of plague contracted in a twice-disinfected house, 14,416.

DISINFECTION—*cont.*

Bombay: In Koli Wadi and a chawl in Parel disinfection effective, 20,431–7.
Bombay: Not a single case among contacts after thorough disinfection of room where patient had died, 25,803.
Bulsar: Re-occupation of houses 10 days after disinfection not followed by plague, 19,957.
Calcutta: Disinfection inefficient, notwithstanding no cases recur, 5615, 7662, 7664.
Calcutta: From the time when disinfection became efficient plague began to abate, II., 534.
Calcutta: No case known of plague reappearing in disinfected house, 7294, II. 534.
Guntakal Junction: Stops plague, 4183.
Kankhal: Good results of disinfection of every room and of every house, 9045–51.
Panjab: No instance known of recurrence of plague in a house known to be infected after its disinfection, 10,047.
Poona: Value of disinfection exemplified in the case of Wanaori Bazaar, and by fact that cases occurred on re-entering houses only limewashed, but not those chemically disinfected, 10,970, 10,972.

Instances in which House Disinfection did not stop Plague:

Belgaum: Disinfection did not stop plague in, 22,867.
Hardwar: Alone not sufficient to stop progress of plague, 9035.
Houses are still dangerous, even if disinfected, for re-occupation after only one or two weeks, 20,158.
Igatpuri: Complete disinfection does not stop the spread of plague, 19,455–67, 23,317, 29,196.
Jawalapur: Insufficient to stop course of disease at, 9175.
Lanauli: Disinfection not effective in, 20,184, 20,197.

See Recurrence.

Opinions regarding Value of Disinfection:

Bacillus dies in time without disinfection in about four months, 22,663.
Bacillus dies out without disinfection in two months, 22,713.
Bacillus of plague not killed by disinfectants, but by lapse of time, 11,531.
Bacillus survives application of disinfectants to infected floors, 5159.
Chemicals are very costly and do not give absolute results, 22,546.
Chemical disinfection not worth the money spent on it, 11,273, 24,448.
Chemical disinfection no use for Indian houses, burning the only cure, 15,178.
Chemical disinfection proved by experience to be unnecessary, ventilation and evacuation sufficient, 24,036–40.
Chemicals have not produced results to warrant the cost, 19,515.
Chemicals not to be relied on at all, 22,327.
Chemical disinfection: The fact that the plague germ can be killed by experiments in laboratories does not guarantee its destruction under natural conditions, 22,325.
Comparison between the number of bacteria found in a house before and after its disinfection no test as to its value, 26,369.
Comparison of the growth of colonies obtained from wall scrapings before and after disinfection showed no great difference. 26,350.
Details of experiments to determine the efficacy of the methods used for plague-infected houses, III. 345.
Disinfection by chemicals only useful in so far as the houses are cleaned out and aired in the process, 22,864.
Disinfection of clothing useful, but of houses impracticable, 23,187–8.
Disinfection of house by chemicals inefficient 20,158–61.
Disinfection by various fluids does more harm than good, 24,935.
Disinfection without evacuation sufficient for imported cases, 22,82–96.

DISINFECTION—*cont.*

Disinfection unnecessary if houses vacated for three months and ventilated, 24,040.
Evacuation and opening up of houses for a month more effective than chemical disinfection, 24,449.
Evacuated houses left unoccupied for two or three months proved safe without chemical disinfection, 19,955.
Even when most carefully done not always adequate to destroy the infection, 16,236.
If a thoroughly satisfactory measure, it ought to destroy the germ at once, 23,191.
No use when badly done, 18,768.
Not complete if any micro-organisms can be discovered after, 5188.
Of houses in towns not worth the enormous expense it entails, 11,266.
One process not sufficient, 10,325.
Repellant, not a destructive agent, 22,162.
Scientific disinfection of large areas an impossible measure, 12,757.
Sun does the work much better than chemicals, 24,342.
Thorough disinfection of every house in the place necessary measure in cases of plague, 9436.
To be effective must be lasting, II. 13.
Valuable if quite efficient, but difficult to get it properly done, 7991–4.
Ventilation as effective as disinfection by chemicals, only slower, 22,059.
Very little use if done several days after the infection has had a start, 25,130.

Opinions regarding Disinfection combined with other Measures:

Evacuation, combined with disinfection, ought to take the first place in plague measures, 18,422, 19,952.
Evacuation must be combined with the disinfection of the infected area and persons, 10,363.
Evacuation, cleansing, and disinfection the most important measures in dealing with plague, 16,969–71, 16,987.
Evacuation, segregation, and disinfection valuable in the order named, 23,032.
Failure when not combined with segregation, 18,426–8.
Useless without evacuation, 14,441, 19,484.

Rules for and matters connected with the carrying out of Disinfection:

Bangalore: Directions for disinfection of houses in, 2707.
Bombay Presidency: General procedure in, 8, 9.
Compensation paid at Hardwar for destruction of property, 9312.
Government compensation in the N.W. Provinces for loss by disinfection, 8841.
Houses should be opened up before use of chemical disinfectants, 24,124.
More efficient if done by fire engines, 8269.
More penetration when steam or strong hand pumps are used, 915.
Mysore: Rules for, in the Mysore State, 25,099.
Panjab: Rules for the disinfection of houses, 9984, 9996, 10,014–42.
Panjab: General mode of disinfection in the villages of the, 10,475–9.
Poona: Method of house disinfection, 21,289.
Steam engines used to flush down houses, 945.
Ten days interval before disinfecting houses, because dangerous before, 5529.
The rule to allow an interval of 10 days between evacuation and disinfection of no practical value, 10,044, 10,566, 10,788.
To give time for epidemic among rats to cease, disinfection not begun till 10 days after evacuation, 10,473.

DISINFECTORS:

Plague Cases among:

Ahmadnagar: Coolies employed in unroofing contract plague, 24,210.
Ankleshwar: No cases from whitewashing houses disinfected with perchloride of mercury, 14,237.
Cases among disinfecting gangs, 7220.
Cutch Mandvi: Attacks among disinfectors, 13,480.
Hyderabad State: Sweepers employed in cleaning infected houses frequently attacked, I. 442.
Jamalpur: 3 of the 34 cases were in disinfectors, 9158.
Jawalapur: 29 cases connected with disinfectors, 8929, 9178, 9217.
Kankhal: 4 of the 38 cases were in disinfectors, 9221.
Karachi: Cases common among disinfectors before their inoculation, 11,769, 22,668.
Kotri: 5 out of 100 cases in disinfectors, 12,647.
Palanpur: Disinfecting parties attacked, 13,100.
Panjab: Cases among disinfectors, 10,603–25, 10,625.
Panjab: Disinfectors attacked in every village before inoculation applied to them, 10,681–6.
Panjab: Disinfectors did not suffer from pneumonic plague to any marked degree, 10,340.
Panjab: 50 cases among disinfectors (total cases 3407, 9981), 10,001.
Panjab: Lime washers attacked, 10,323.
Panjab: List of some cases among disinfectors, 10,384.
Panjab: Mahlgahla—disinfectors attacked, 9987, 10,139, 10,349–41.
Punjab: Precautions taken with disinfections, 10,003–14.
Panjab villages: Disinfectors attacked, 10,143, 10,145, 10,146, 10,468.
Poona: No attacks in disinfecting gangs, 21,414.
Rohri: No plague among disinfectors, 12,089.
Satara: Attacks of disinfecting coolies, 22,720–7.
Sukkur: A large number infected by a plague case in a temple, in which five disinfecting coolies also died, 18,403.
Surat: A carpenter washing on disinfection with a wound on his foot attacked, 16,007.
Thana: Two men sent to clean a house where dead rats had been found got plague and died, 220.
Umreth: Two plague cases among Golas sent from segregation camp to limewash their houses, 14,067.

Risks run by Disinfectors, and Precautions against:

Boots and clean hands prevented disinfecting staff from taking infection, 16,007.
Digging up floors: Danger minimised by first white washing, 5554.
Disinfection dangerous work, many disinfectors attacked, 10,000.
Disinfection not dangerous to the gangs with proper precautions, 10,790–1.
Good results of inoculation among coolies on disinfecting gangs, 10,006–8, 10,681–6, 10,690–4, 11,769, 22,686.
No cases of mercurial poisoning among disinfectors, 10,020, 13,632, 19,939.
Panjab: Precautionary rules for the workers on disinfecting gangs, 10,003.
When careless of precautions disinfecting gangs as liable to plague as other persons, 22,721.

DISINFECTORS—*cont.*

Supervision and efficiency of Staff:

Bombay: At beginning of epidemic no special disinfecting staff. 1147–50.
Bombay: Staff trained to disinfection work, 1680.
Coolies shirk disinfecting work and require strict supervision, 7862, 21,096, 24,450, II. 13.
Disinfection requires continuous supervision, 8055, 23,189.
Disinfectors in villages open to bribes and careless about matters they consider unimportant, 21,154, 21,174.
Hubli: Disinfectors found to be taking bribes to shirk their work, 23,366, 23,399.
Just as well in hands of instructed laymen as of doctors, and no waste of power, 7970–3.
Native agency inefficient, 7862.
No staff to carry it out in villages, 2145.
Ought not to be left to inexperienced hands, 15,229.
Panjab: The Commissioner of the division issues the rules for the disinfection of infected areas, 10,661.
Poona: Disinfection always done under European supervision, 21,397–8.
Requires a great deal of supervision, 17,656.
Requires European supervision, 21,097.
Requires trained staff, 1680.
Should be entrusted only to trained hands 14,438.
Staff Corps officers supervise disinfection, 7971–6.

See Flying Columns.

DOG:

Dog died of plague in Daman, I. 378.
Dog seen with plague in Daman by Mr. da Cunha, and several heard of, 16,546.
Dog taken ill in Calcutta after taking up dead rat, 7187, I. 474.

DOMES:

Domes are natives of a certain caste who do not object to touch dead bodies, 6988.
Domes: Calcutta; get clothes of dead and assist at cremations, but had no plague, 7666.
Domes infected when assisting at post mortems, 6923–5, 6988–95, 6462, 6493, 6503–6, 6921.

DORMANCY OF PLAGUE.

See Interval between introduction of plague and outbreak.
,, Recurrence of plague in infected towns and villages.
,, Recurrence of plague in the same house or locality.

DRAINAGE:

Ahmedabad: Scheme for the drainage in course of execution at, 13,961.
Bombay: Mandvi, drains are bad, 17,934.
Bombay: More than a quarter of the island without drains, 25,741.
Bombay: Shone system of drainage introduced in certain districts, 25,752.
List of places where drainage and waterworks have been completed, I. 277–8.

Plague and Drainage:

Ahmednagar: Plague broke out in the most unhealthy part the town, where there was no drainage system, 22,264.
Bombay: Sewer pollution not the cause of plague, 19,437.
Karachi: Drainage system not responsible for the severity of the outbreak, 22,651.

DURATION OF PROTECTION AFFORDED BY INOCULATION.

See Inoculation with Haffkine's plague prophylactic.

DURATION OF SICKNESS IN PLAGUE:

Average duration of fatal cases three to four days, 2361.
Duration of disease averaged 5½ days in 17 fatal cases, I. 381.

DURATION OF SICKNESS IN PLAGUE—*cont.*
Instance of plague case of only 14 hours' duration, 17,580.
Minimum duration of plague case under 18 hours, 9607.
Mortality very high during first five days; highest on the second day of attack, 10,207.
Non-fatal cases, 10 to 15 days, 2362.
Table of mortality from day to day of the disease in the Jullundur district, II. 96.

DUST.

EFFECT OF PLAGUE ON OTHER DISEASES:
Decrease in malarial fever during plague, 12,993, 16,505–7.

ELECTROLYSED WATER:
Plague bacillus killed by freshly electrolysed water, with chlorine in solution, 3632.

EMIGRANTS:
All emigrants at Mombassa were detained at Kiamari, 11,989–92.
No emigrants under contract allowed to depart from Karachi at all, 12,233.

ESTABLISHMENT.
See Staff, Plague.

EURASIANS, CASES AMONG:
Bombay: Death-rate from plague among Eurasians 43 per cent; among Europeans 32 per cent., I. 382.
Calcutta: Small percentage of Eurasians die at, 6870.
Death-rate among Eurasians at St. George's Hospital, Bombay, I. 391.
Poona: Sassoon Hospital, six deaths among 16 Eurasians in, 12,931.

EUROPEANS, CASES AMONG:
Bombay: Death-rate from plague among Europeans 32 per cent. of cases; among Eurasians, 43 per cent., I. 382.
Bangalore: Case of a European, 2600.
Bangalore: West Riding Regiment, cases among the men of, I. 173–4.
Course of disease the same among Europeans and natives, but the former showed more resisting power, 12,935.
Death-rate among Europeans and Eurasians at St. George's Hospital, Bombay, I. 391.
Few cases among Europeans, 330, 332.
Immunity: Almost entire for Europeans, 17,685.
Immunity: Europeans not so immune in former times as now, 22,263.
Immunity: Europeans have no racial immunity, 296.
Immunity: Europeans probably have racial immunity, 6969.
Immunity: Europeans on Malabar Hill escaped, whilst their servants contracted the disease, 1447, 18,189–99, 20,478, 20,539.
Immunity: Fresh air accounts for immunity of Europeans, 22,426.
Immunity: Healthy Europeans relatively immune because they sleep in beds and wear boots, 19,447.
Immunity: Ventilation accounts for immunity of Europeans, 917, 7168.
Notes of cases among Europeans, 7220.
Panjab: Sanitary inspector, death from plague of European, at Mahlgahla, 10,348.
Poona: One death among 17 Europeans in Sassoon Hospital, 12,928.
Poona cantonment: Cases among European soldiers, 21,293.
Three cases among, 7569–77.
Yersin's serum ineffective in plague case of a European girl, 1468.

EVACUATION:
Arranged under the following subheads:
Attitude of the People towards Evacuation.
Beneficial results of Evacuation: Instances and opinions in favour of.
Compulsion and Evacuation.
Difficulties connected with Evacuation.
Early Evacuation: Opinions and Instances connected with the Advantages of.
Length of Period of Evacuation.
Limit of Population which can be Evicted.
Limit of Population, 5,000–20,000.
Limit of Population, 20,000 and upwards.
Limit of Population, no limit.
Partial Evacuation: Instances and Opinions regarding.
Seasons favourable for Evacuation.
The Rains and their Effect on Evacuation.
Time taken to effect Evacuation.
Total Evacuation: Opinions and Instances regarding.
Unnecessary or Unsuccessful: Opinions and Instances that Evacuation is.

Attitude of the People towards Evacuation:
Agriculturists go out into evacuation camps without difficulty, 22,986.
Bandra: Impossible owing to the opposition of the Muhammadans, 18,929.
Bangalore: Evicted people will not go into camp and overcrowd other districts, 2580.
Baroda: The majority of the population are now convinced that evacuation is a beneficial measure, 14,635, 15,115–6.
Bhiwandi: People refused to comply with the orders for evacuation, 14,522.
Bombay: Parsees go readily to camp, 8294.
Bombay: The trouble of removing real cause of the objections to camps in, 18,261.
Co-operation of the people in reporting cases in camp necessary, 14,421.
Dharwar: Majority of people left town for camp of their own accord, 1612.
Dharwar: The most remarkable results from using no force but working with the people, 26,543.
Ghoti: The residents who last year forcibly resisted evacuation, are now thoroughly convinced of its efficacy, and went out and stayed out themselves in the rains, 14,758.
Guntakal: Takes time because of Muhammadan objections, 4145, 4161.
Hyderabad State: Villages around go out of their own accord, 5455.
In districts that have had experience of plague, people evacuate villages of their own accord, 9.
Kankhal: People settled down very easily and quietly to their temporary life in camp, 9343.
Kankhal: No opposition offered to evacuation, 9096, 9109.
Karachi: People as a rule do not like to go into segregation camps, 11,635.
Mahamari: People vacate villages of their own accord on appearance of, and will probably act similarly when they get to know plague, 26,575.
Muhammadan population makes evacuation impossible, 5462.
Muhammadans have an almost insuperable objection to, 3414.
Mysore State: Villagers evacuate their houses of their own accord on the appearance of plague, 3303.
Mysore State: Villagers evacuated villages willingly, 3304–5.
Natives themselves convinced of its advantages and will take initiative, 9, 11,378, 15,116, 15,494.
Native gentlemen use their influence and secure evacuation, 1345.
Panjab: Cordons and evacuation the measures natives most dislike, 10,310.
Panjab: Palewal: Evacuated under most favourable conditions through influence of the principal inhabitants, 10,725, 10,728.
People mostly object to go to segregation camps because of the trouble of removal, 18,261.

EVACUATION—*cont.*

Property: People object to go to camp from fear regarding safety of property left in their houses, 3321, 4970, 5007.
Ryots go out quite readily, but traders mostly object, 22,092.
Satara: Great difference in the attitude of the people between first and second epidemic, 22,558.
Satara: Opposition to evacuation mostly from Brahmans, Banniahs, and Sahukars, 22,623.
Satara: People frequently evacuate their villages of their own accord, 22,089.
Segregation camps popular with the people, 12,522.
Sholapur: Caused discomforts, but no complaints, 20,265.
Shopkeepers and weavers have to be frightened out, 5456.
Sind: Two villages voluntarily evacuated, 12,086.
Surat: People object chiefly to evacuation and segregation, 15,865.
Thana district: No opposition to evacuation, segregation very unpopular, 18,788.
Umreth: Only slight opposition offered by the people to the orders of evacuation, 14,040.
Villagers recognise usefulness of evacuation, 22,635.
Villagers now thoroughly convinced that evacuation is a beneficial measure, 14,635.

Beneficial results of Evacuation: Instances and opinions in favour of:

Ahmednagar: Sanitary improvements carried out in cantonment while people were in camp, 24,191.
Ankleshwar: Plague practically stopped within a month after evacuation, notwithstanding the rainy season, 14,403.
Ankleshwar: Table showing results of partial and total evacuation, II. 244.
Ankleshwar Taluka: Particulars of cases before and after complete evacuation, II. 250.
Banga: Statistics relating to evacuation, II. 97*a*.
Banga: Table showing the effect of evacuation in, II. 112.
Banga town: Table showing the effect of placing people in camp at, II. 99.
Bangalore: Of complete streets very successful, 3396, 3399, 3440.
Bangalore: Effect of regimental evacuation, 3396, 4889.
Baroda: Evacuation stopped plague in villages which were reoccupied without recrudescence, except Savali, 14,630, 14,658.
Belgaum: Good effects of removal to health camps noted in the case of a particular family, 23,041.
Beneficial effects of camp life under supervision, 16,016.
Beneficial in forcing the people to live in the fresh air, 19,498.
Bholana: Two families left in got plague; no cases in camp except from contact or visits to village, 24,545, 24,561.
Bobleshwar: No plague in people who went to camp; one family that remained in got plague, 19,513.
Chipagiri: One hundred and fifty go out from infected area. No cases in camp; two persons who refuse to go out die of plague, 4967–70.
Conclusions from the results of evacuation, 20,238.
Cutch State: Table showing results of evacuation in the villages, II. 409–10.
Cutch State: People who left villages got no plague, but the Jadejas who remained in contracted it, 13,449–50.
Dharwar district: Good effects of evacuation well marked in the villages, 1699, 23,168, 26,543–4.
Dharwar: Statement of plague during evacuation and subsequent to it, III. 355.
Dharwar district: Table of results of evacuation in, III. 214.
Disinfection should be supplemented by evacuation, 14,441–19,484.
Effect of health camping at Poona was magical, 21,320–1.

EVACUATION—*cont.*

Effects immediate; no measure so effective, 20,441.
Evacuation and opening up of houses for a month more effective than chemical disinfection, 24,449, 24,456.
Evacuation brings down mortality at once, 23,202.
Evacuation, combined with thorough disinfection, ought to take the first place in plague measures, 10,361–3, 18,422, 19,952.
Evacuation completely successful, chief measure in Bombay Presidency, 5, 9.
Evacuation essential, 13,191, 16,967–71.
Evacuation excellent in small places, but impossible in large cities, 7854, 18,585.
Evacuation first and most important measure, 22,288–9.
Evacuation frequently stopped plague in a week, 15,124.
Evacuation lessens mortality and decreases the duration of the epidemic, 26,543.
Evacuation stops the epidemic in the hot weather in some villages, 9988.
Evacuation stops the epidemic from extending, 10,464, 10,757, 25,186.
Evacuation successful in Gulamshah village, where plague and small-pox at the same time in the Gulamshah camp, 11,138.
Evacuation the best measure for combating plague, 11,849–50, 13,452, 14,396, 15,221, 15,764, 19,684, 22,031, 22,532, 22,595, 22,891, 23,507, 24,312–3, 26,672.
Evacuation the most effective remedy, as plague seems to be principally a disease of locality, 8791, 17,666, 26,672
Evacuation the real remedy, 1061, 10,634, 11,248–51, 11,482, 15,115.
Evacuation, segregation, and disinfection valuable in the order named, 19,639–41, 23,032.
Evacuation with opening up and cleaning houses the best remedy, 24,363.
Excellent measure, if combined with segregation, 11,482, 12,051, 21,667.
Followers of 4th Hussars moved with entire success, 2839.
General course of disease after evacuation, 9986.
Gharibabad part of Sukkur: Most successful (1,000 inhabitants) in, 3725–37, 3813–6, 4275, 11,162–70, 18,405–8.
Health of the people from camp life, beneficial effects on the general, 15,169.
Health, segregation camps exert a most beneficial influence on the general, 21,719.
Hinganghat: Very successful, 6032–6.
Hoshiarpur district: Table showing effect of evacuation on the epidemic, II. 82.
Immediate benefit following, 2.
Instances of beneficial results of, 13,449–51, 22,737.
Inoculation, combined with complete evacuation, the ideal plague measures, 22,408.
Jalgaon, mill hands all put out at once at, with the result that not one case occurred among them, 24,563.
Jullundur district: Table showing effect of evacuation on the outbreak, II. 80, 81.
Jullundur and Hoshiarpur districts: Table showing period between the date of the total evacuation of the villages and the date of the last case of plague, II. 83.
Kaira district: Statistics relating to evacuation in villages, II. 424–40.
Kaladgi: Complete evacuation caused the plague to subdue within two weeks, 19,475.
Kalankot: Successful, 4273.
Kalankot: Good results, 11,144.
Kankhal: People who were allowed to remain in evacuated quarters got plague, while those evicted benefited, 9217.
Karachi: Good results of camps in healthy spots with efficient supervision, 11,314.
Karachi: Good effects of evacuation, 11,959–60, 12,755.
Khandraoni: Evacuation successful at, 9661–4.
Khari: Successful results, 18,936.
Kotri: Table showing the beneficial result of evacuation, 12,654.

EVACUATION—*cont.*

Mysore: Barr Sepoys attacked and marched out into camps; disease stops at once, 3,397.
No fair test to compare the number of cases before and after evacuation, 9992.
North-West Provinces: Good results of evacuation, 9225.
Palanpur: Results obtained very strongly in favour of entire evacuation, 13,160.
Panjab: Statement showing effect of evacuation in the villages, II. 80–3, 112, 117, 403.
Panjab: Table to show effect of evacuation of villages on the epidemic of plague, II. 83, II. 117.
Plague always went down after evacuation, 3306, 5926, 6036, 14,662, 18,582, 19,482, 22,046, 24,549.
Porbandar: Table showing effect of evacuation on the different communities, II. 222.
Quick and certain method of stamping out plague, 10,361.
Removal from the vitiated air the most beneficial result of, 23,035.
Second outbreak after disinfection easily checked by evacuation of the re-infected houses, 10,053.
Sholapur: Effects of evacuation at, 20,233, 23,928–33.
Sirohi State: Success of evacuation in villages, 9825–9, 9830–3, 9862–6, 9873–7.
Stopping the plague, hygienic conditions of camp life and release from dread of plague, powerful agents to, 11,894.
Success depends on efficiency of staff, 10,297.
The more complete the evacuation the sooner the spread of the disease is stopped, 22,032.
Though evacuation of a place may do harm, by causing refugees to carry plague to neighbouring places, less harm will be done by resorting to evacuation than by not resorting to it, 23,336, 26,546–7.
Total evacuation the most effective plague measure, 11,248, 15,220, 15,764, 18,082, 19,684, 20,441.
Total evacuation with disinfection most satisfactory, 18,421–2.
Unkal: Successful, 2194.
Utmost importance to evacuate thickly populated infected area, 4292.
Wagdari: Effect on death-rate, 5926.

Compulsion and Evacuation:

Bandra: Evacuated by force, 18,570–3.
Bangalore: Refusal to enter Government camps at, 2551.
Broach: Compulsory evacuation of infected houses, 15,489.
Dharwar: Difficult to get people to camp provided by Government, 1934.
Municipal and Government camps, objection to, 12,527.
Official interference objected to much more than evacuation, 16,137.
Sholapur: All compulsory camps at, 20,241.
Surat: People at, refused to go to Government camps, but made camps of their own, 15,914.
Total evacuation should not be persisted in where people object, 26,546.
Wholesale compulsory evacuation of infected areas a most useful measure, 11,849.

Difficulties connected with Evacuation:

Arrangements in Broach to carry on the mills while people in camp, 15,484.
Bombay: Little done in the way of evacuation during the first epidemic owing to the difficulty of providing temporary accommodation, III. 362.
Bombay: Necessity for camps built near centres of work, with free passes given on railway to workmen living in the camps, 8273.
Easy at Cutch Mandvi, 466.
Fires occurred in the private camp at Jawalapur, by which much property was destroyed, 9343.
Found possible in Jalgaon to carry on the business of the town with the people in camp, 24,563–4.
Houses evacuated sometimes burned, 23,675–7.
Inconveniences of evacuation greater among the better classes than the poor, 14,457.

EVACUATION—*cont.*

In voluntary camps at Karachi thefts frequent, 11,883.
Property left in evacuated houses sometimes stolen, 5455, 22,639.
Rohri: Done in sections in order to keep trade going, 12,039.
Rohri: Plague continued a month after evacuation, as the people remained with their sick concealed in the date plantations, 12,107–19.
Trades and several occupations of the people a great factor in the difficulties of evacuation, 10,296.
Trade in large towns paralysed by evacuation, 13,1956.
Zanana chief difficulty in evacuation, 5463.

Early Evacuation: Opinions and Instances connected with the Advantages of:

Alibag: History of plague at, most instructive in showing the advantage of early evacuation, 17,611, 17,614.
Co-operation of the people and efficient assistance of subordinates indispensable for the good results of early evacuation, 14,421.
Cutch Mandvi: Good results in most villages turned out early, 13,452.
Evacuation by instalments not so definitely beneficial as prompt evacuation, 23,202.
Gives good results if effected in time and combined with early information, 26,675.
Instances of the benefits of immediate evacuation, 22,737.
Instances in which the spread of the disease was arrested by early evacuation, 14,419, 18,582–4, 21,639.
Kaladgi: Excellent results of prompt evacuation, 23,635.
Most effective when immediately applied, 18,764.
Must be complete, and undertaken at the first stage of the epidemic, 24,312–4.
Partial evacuation failed in many cases because not early enough, 19,638, 23,536–43.
Promptness of evacuation most important, 9281–3, 10,616, 21,667, 22,599, 22,737, 23,169, 23,589, 24,199, 24,545.
Upper Daman: Early evacuation stops the disease, 16,466.
Wasind: Evacuation before the first indigenous case stopped the disease at once, 19,654.

Length of Period of Evacuation:

Time of absence has to depend on circumstances, 575.
At Poona, street by street inhabitants back after disinfection within a week, and had no further plague, 15, 10,928–37.
Period 10 days, sometimes a month or more, 8301.
At the commencement of outbreak in Rohri, infected houses evacuated for 10 days, and all their inhabitants segregated, 12,027, 12,033.
Plague cases re-appear in disinfected houses if only left vacant for 10 days, 25,198.
People might be allowed to return to their houses 10 days after efficient disinfection, 10,378.
Bombay: People allowed to return after 10 days, 10,957.
Poona: People allowed to return after 10 days, 10,929.
Sweepers' quarter at Belgaum evacuated and re-occupied in 10 days, when more cases, and residents were then cleared out indefinitely, 2090–7.
Infection not stopped in 10 days, if return to infected areas is allowed, 11,902.
If incubation period is accurately known, three weeks a sufficient time for keeping people out of their villages, 10,789.
Three weeks the minimum period of evacuation in the Panjab, 10,570.
Period of evacuation ought not to be less than three weeks after last cases of plague, 10,054, 10,266–70.
Palanpur: People kept out three or four weeks, 13,134.
Time requisite, with disinfection of houses, at least three weeks, 10

EVACUATION—*cont.*

Evacuation and opening up of houses for a month more effective than chemical disinfection, 24,449, 24,455.
People should be allowed to return one month after deaths stop in camp, 5451.
People kept out for one month in Dharwar villages, 2141, 23,748.
Maintained at Sukkur for one month, 3727.
Period of one month after disinfection at Hubli, 1563.
Villages should be evacuated at least a month; the longer the better, 13,456.
Re-occupation within six weeks after evacuation and disinfection unsafe, 16,247, 20,158.
Baroda: people kept out between six weeks and two months, 14,687.
Two months evacuation quite sufficient, 11,380, 11,493, 12,763, 12,791, 22,714.
Villagers kept out for two months in Hyderabad, 5926.
Evacuation without disinfection of houses should last two or three months, 10.
Houses left unoccupied for two or three months proved safe without chemical disinfection, 11,379–80, 19,955.
People of Kotri kept out 2½ months, 3759.
Should extend to three months after the last case, 22,841.
Sholapur kept empty from December to March, 23,916.
Return to houses safe if they have been vacated three months and ventilated, 24,040.
Three months the longest period in which people were kept in camp in the Ankleshwar Taluka, 14,422.
Kankhal: people out from end of October to middle of February, 9102, 9117.
Houses should remain evacuated for about four months, 22,533.
Karachi: Evacuation into voluntary camps began in April. People had all gone back to town by the end of August, 11,876.
Bangalore: people allowed back only when house considered free of infection, 2580–2.

Limit of Population which can be Evicted:

Complete evacuation impossible for very large places, 8798.
Evacuation in large towns is really a matter of finance, 21,803.
Impossible in a big city; only leads to concealment of cases, and frightens people away, 7854, 8272.
Much easier carried out in agricultural villages, where the people are tied to the spot by their occupations, 24,072.
Of large numbers comparatively easy when the infected place is surrounded by open country, 18,586.
Total evacuation impossible in Bombay, 18,588.

Limit of Population, 5,000–20,000:

Banga and Garhshankar, 5,000 inhabitants each, evacuated, 9980.
Complete evacuation of Kotri (6,000 people), 3752.
Impossible to control 18,000 persons out in the fields, 24,556.
Impossible to control village of 4,500 with the staff available, 24,065–70.
Malegaon, about 12,000 people in health camp at, 18,074.
Possible in most towns of 10,000 inhabitants, 10,296, 18,787.
Rahon, population 8,000 to 10,000, evacuated, 10,459.
Six thousand or 7,000 successfully evacuated at Kowloor, 5453.
Total evacuation of Malegaon, with a population of 18,000, in about a fortnight, 13,777.

Limit of Population, 20,000 AND UPWARDS:

Can be applied to a town of 60,000 inhabitants, but impossible in large towns like Bombay and Surat, 11–12.
Could be done easily up to 100,000, 26,546.
Cutch Mandvi: between 30,000 and 35,000 evicted in second epidemic, 13,424.

EVACUATION—*cont.*

Evacuation of Karachi on second epidemic, population, 40,000, 3773.
Impossible in large cities, 7854.
Karachi: about 30,000 in camp at one time, 11,318–20.
Maximum population evacuated 70,000, 5460.
Surat, about 35,000 at one time in the municipal and health camp in, 24,420.
Surat: Thirty-four thousand persons evacuated at one time, 15,766.
Town of 70,000 Hindu inhabitants easily evacuated, impossible if the population is Muhammadan, 5462.

Limit of Population, NO LIMIT:

No limit to, if done in sections, as far as population is concerned, if accommodation can be provided, 26,689.
Under favourable local conditions no limit to, but that of expense, 18,586, 18,784.

Partial Evacuation: Instances and Opinions regarding:

Ahmedabad: Evacuation of the infected locality and disinfection proved sufficient, 13,937.
Ahmedabad: The dryness of the atmosphere probable cause of partial evacuation proving there more successful than at other places, 13,937.
Ahmednagar: Partial evacuation resorted to unsuccessfully, and town at last totally evacuated, 24,234, 24,253–5.
Bangalore: About 75 per cent. of population evacuate their houses themselves, 3481.
Bangalore City: Evacuation at first confined to infected houses, 3232.
Bangalore: Complete street evacuated and very successful, 3396, 3399, 3440.
Baroda City: Partial evacuation having failed, whole town was evacuated by March 1898, 14,613–4
Baroda: Inoculated persons not forced to evacuate their houses in the villages of the Baroda district, 15,084.
Bombay City: Evacuation not attempted on a large scale, 11–13, 1345.
Bombay: Evacuation among the Parsees in the Fort restricted to houses in which plague cases occurred, or dead rats were found, 25,247.
Broach: Partial evacuation resorted to, 15,486–91.
Calcutta: Houses adjoining infected houses not emptied, 6580.
Chipagiri: Partial evacuation succeeded, 4964–73.
Cutch Mandvi: Partial evacuation checked but did not stop plague, 13,453.
Evacuation by instalments not so definitely beneficial as prompt evacuation, 23,202.
Evacuation of the whole village preferable to its disinfection block by block, 10,349.
Guntakal: Partial evacuation unsuccessful, 4144.
Hardwar: Only partly evacuation resorted to successfully, though all but 500 people left the town voluntarily, 9039–44.
Hubli: Clearing and burning down streets did not check progress of disease across the town, 1645.
Hubli railway chawls, 2403.
Hyderabad: Village evacuated, people lodged in railway waggons, 19,468.
Instances in which partial evacuation was not successful, and instances where it proved sufficient, 23,241–4.
Jawalapur: Partial evacuation failing, was totally evacuated, 9173–7, 9276–8.
Kankhal: Evacuated in sections, had to be totally evacuated, 9090–4, 9101–2, 9113.
Karachi: Evacuation done in sections; a very great undertaking, 26,676.
Karachi: Methods of evacuation and segregation modified in the course of the epidemic, 11,143, 11,219–23.
Karachi: Joria Bazar evacuated on 7th April 1898; people allowed to go where they pleased, went to other parts of the town, 11,240.

EVACUATION—*cont.*

Karachi: Very large part of native town evacuated in May 1898, 11,242–4.
Kotri: Dhobi quarter evacuated at beginning of outbreak, 12,551.
Kotri: Does not stop disease at, 3755.
Malegaon: Partial evacuation unsuccessfully tried, 18,070–5, 23,241.
Molagavelli: Partial evacuation failed, and whole village was evicted, 4992, 4999.
Nasik: Evacuation began with the Musulmans and Kalals, 24,481.
Nasik: Gradual evacuation of infected areas until three-fourths of the town were evacuated, 13,751, 13,771, 16,929–44, 23,241.
Nominal evacuation no use, 22,041, 22,045.
N. W. P.: Partial evacuation succeeded in villages where first case detected, 9134.
Palanpur State: Partial evacuation insufficient in the villages, 13,124, 23,241.
Panjab: Banga: Muhalla system of evacuation very unsatisfactory, 10,172, 10,232–5.
Panjab: Bilron: Partial evacuation and cordoning of the area successful, but the village re-infected from outside, 10,741.
Panjab: Partial evacuation in villages failed, 9977–9.
Partial evacuation a danger to the surrounding villages, 20,237.
Partial evacuation did not stop progress of plague, 24,431.
Partial evacuation inadequate, 10,231, 11,126, 19,459.
Partial evacuation may succeed if infection is in a block of houses separate from rest of town, 18,783.
Partial evacuation sufficient if early intimation of the first case is obtained, 13,797.
Partial evacuation very little good. Disease gets across open space, 1710.
Poona: No evacuation during first epidemic, but rigorous plague measures, 21,690.
Poona: Partial evacuation in first epidemic, 10,921.
Satara: Only partially evacuated—plague kept on, 22,297.
Sholapur: Partial evacuation not successful, 20,231-3.
Sinnar: Partial evacuation proved inadequate; total evacuation ordered, 13,790.
Sirohi State: Partial evacuations failed, and villages totally evacuated, 9821–2.
Sukkur: Success with 600 people, 3816.
Surat: Adopted in, during second epidemic, 15,734, 15,883, 24,430–1.
Timmencherla: Partial evacuation successful, 4124–8.
Trade not affected by piecemeal evacuation, 17.
Umreth: Partial evacuation ineffective; town completely evacuated on November 24, 14,041.
Undhera: Partial evacuation tried at, proved inefficient, 14,648.
Wardha: Nearly the whole evacuated, 6120.

Seasons favourable for Evacuation:

Ahmednager: People complained both of the cold and heat in camp, but ultimately preferred camp life, 18,996.
Evacuation successful in every season of the year, though more troublesome in winter than in summer, 10,361.
May and June the most favourable months of the year for evacuation in the N.W. Provinces, 8804.
Panjab: People complained of heat in hot weather, but suffered little with camps under trees, 10,239.
Plague can always be controlled without much expense and without compulsion in up-country districts during the dry season, 26,544.
Sirohi: People objected to go into camp on account of the cold, 9912.

The Rains and their Effect on Evacuation:

Ankleshwar: Plague stopped within a month after evacuation, notwithstanding the rainy season, 14,403.

EVACUATION—*cont.*

Bandra: Impossible, owing to the rains and the opposition of the Muhammadans, 18,929.
Bangalore: People driven out from the health camps by rains, 3267.
Cutch Mandvi: Salaya and Bada, people return to villages from camp on account of rains, with recrudescence of plague, 13,456.
Dharwar: Byahatti and other villages: Epidemic extremely severe where evacuation was impossible on account of the rains, 2168–93, 2192.
Dharwar: Villages in which plague was severe, as evacuation was impossible on account of the rains, 1601, 1719, 23,518, 1. 92–3, 2168–2200.
During rains, entails great sufferings, 22,761.
During rains evacuation unsuccessful because huts built too solid and without ventilation, 22,048, 22,607–9.
During rains, exposure to cold and damp in the camps renders people more susceptible to plague, so that evacuation then fails, 22,737.
During rains, makes people more liable to the disease, 23,273.
Financially impossible to provide adequate shelter for the evacuated during the rainy season, 16,079.
Flat roof of houses the best place to camp people in black soil country if plague occurs during the rain, 23,591.
Hardships much greater in the rains in some parts than in others, 22,990.
Hubli: Wholesale evacuation not attempted, because impossible on account of the rains, 1943, 2001.
Igatpuri: Heavy rainfall interferes with evacuation, 16,887, 23,196.
Impossible in black soil, during the rains, without great hardships to the people, 24,560.
Impossible in the rainy season unless accommodation be prepared beforehand, 15,148.
Impossible on clay soil during rains, 5879.
Impossible to carry out completely in the rains, 5525, 22,606–10.
No increase in the mortality from other diseases, notwithstanding evacuation took place during the rains, 24,033.
Of rice-growing district in rainy season requires great and costly preparation, 22,196.
Panjab: Chak Kalal people driven back to village from camp by rains; increase of plague, 10,603 (8).
Panjab: In some parts evacuation on a large scale is possible during the rains, 10,237, 10,572.
Panjab: Mallupota: Great discomfort, half the camp under water, 10,236.
People will not stay out of their houses during the rains, 22,041, 22,077.
Possible during rains on rocky or sandy soil, 5878.
Prevention from leaving the town, the alternative in black soil country during the rains, 26,545.
Rains make supervision and evacuation impossible, 1588–9.
Sholapur: Little complaint by villagers against evacuation in the rains, 22,058.
Surat: Rains interfered with evacuation in second outbreak, 15,739.
Surat: Second outbreak during the rains; evacuation impossible, 24,417.
Thorough evacuation impossible in rainy weather, on a black cotton soil, 22,076.
Vathar and other villages: Evacuation unsuccessful, as, on account of rains, people kept on returning to the village from their huts, 22,041, 22,737.
Where rains interfered, percentage of deaths very high, 2169.
See Recurrence of plague.

Time taken to effect Evacuation:

Ahmednagar: The Sadr Bazar evacuated in 24 hours in, 24,145.
Dharwar, When arrangements in working order, villages usually evacuated in three days, 23,163.

EVACUATION—*cont.*

Duration of epidemic depends upon the time the evacuation occupies, 22,600.
Evacuation done in one month at Unkal, 2194.
Guntakal: Evacuation takes one month, 4164.
Hardwar: The time necessary to prepare a camp depends on the supply of materials and facilities of carriage, 9104.
Hinganghat: Five hundred people or more removed in six hours, 5986–8.
Jagjitpur, N.W.P.: Population 1,200, evacuated in three days, 9144–5.
Malegaon: Total evacuation, with a population of 1,800, in about a fortnight, 13,777.
Molagavelli: Takes four or five days, 5009.
Nasik: Evacuation commenced on November 11th, 1897, and completed early in January, 1898, 14,733.
Rahon: Total evacuation, with a population of 8,900, took 20 days, 10,460.
Rohri (5,000 inhabitants): Evacuated piecemeal; operations commenced 17th April; town emptied 30th June, 12,038–41.
Two months necessary for evacuation of 60,000 people, 23,903.
Wardha: Evacuation commenced 6th December 1898; whole town evacuated by end of December, 6218–9.

Total Evacuation: Opinions and Instances regarding:

Ahmednagar: Evacuated November 1897, 2.
Ahmednagar: Evacuation successful, 2008.
Ankleshwar: Totally evacuated by August 23, 14,222.
Backergunge: Inhabitants of village evacuated in a country boat, and entirely cut off from communication with their houses, 6448.
Baroda: Total evacuation of, completed in March 1898, 14,614.
Baroda: Total evacuation of villages in the Baroda district as soon as an indigenous case was discovered, 14,647.
Kankhal: Ultimate evacuation of the whole town, 9094.
Panjab: Total evacuation of a village as soon as more than one case appeared, 10,451.
Sholapur: Description of evacuation, 5547.
Sholapur: Wholesale evacuation considered too drastic a measure at the beginning of outbreak, 20,229.
Total immediate evacuation the great remedy, 20,238, 22,595.

Unnecessary or Unsuccessful: Opinions and Instances that Evacuation is:

Belgaum: Disease already on the decline when evacuation was commenced, 22,910.
Daman: Failed, except in the case of the Machis, who segregated themselves, 16,368.
Disinfection without evacuation recommended for imported cases, 22,892, 22,896.
Even without evacuation, plague spends itself and disappears in six or seven weeks from first attack, 16,250.
Instance in which evacuation was not successful in staying the disease, 22,038.
Not necessary if the house be good, 1069.
Removal of people to open places without comfort or protection from weather is as harmful as the disease itself, 24,935.
Rohri: Evacuation did not stop plague, as people took no precautions to keep away from cases after evacuation, and position of huts insanitary, 12,081–2, 12,120–1.
Rough and ready method, 16,016.
Satara: At Limb and Rahmatpur evacuation did not at once stop plague as people went to badly ventilated huts, 22,290–6.
Unnecessary if early notification be given, 16,026.
Uran: Evacuation failed to check plague quickly as huts overcrowded and people revisited houses, 22,752–87.
Worthless unless combined with searching, 21,667.
Would become unnecessary if information could be obtained early enough to limit the zone of infection, 21,711.
See Rats: *Death of rats regarded as a warning of plague, and action taken upon.*

EXCRETA:

All may convey plague bacillus out of the body, I. 374.
Bacillus present in, as a rule, I. 378.
Infection by excreta and discharges, 9418, 18,130, 19,036–40.
Mode of exit of plague bacillus from the body, I. 374.
Rats, excreta of, supposed to cause infection, 15,459.
Rats becoming diseased, taint articles with dung or urine, 992.
Should be disinfected, 318.

See Fæces.
,, Scavengers.
,, Sputum.
,, Urine.

EXODUS OF PEOPLE FROM PLAGUE-INFECTED PLACES:

Causes of:

Ahmednagar: One thousand out of 3,000 run away from fear of plague measures in, 2011.
Bombay: In 1896–7, 300,000 people said to have left the City, 1034.
Bombay: Exodus in 1899 not due to fear of plague measures, 26,563.
Bombay: Plague measures the principal cause of the general flight at the commencement of the epidemic, 20,911.
Calcutta: Panic caused principally by the fear of segregation in, I. 468.
Calcutta: 150,000 to 200,000 people out of 700,000 left the city, chiefly from fear of segregation, 6540–5.
Dharwar: Eighteen thousand persons left in one week for fear of segregation and inoculation, 23,746.
Dharwar: One-third of the people went out, but they were of the agricultural class, 1956.
Enforcement of restrictive measures led to the running away of the people, 17,864.
Evacuation impossible in a big city, only frightens people away, 7854, 8272.
Fear of plague as well as of plague measures determine the exodus at the beginning of the epidemic, 20,249.
Fear of the plague drove the people from the suburbs into the date plantations, 12,079.
Ghoti: Deserted after the riot, 16,901.
Karachi: People in first epidemic encouraged by the authorities to leave, but in the second not allowed to scatter, 11,130–5, 11,303.
Karachi: People running away equally from fear of the plague and the plague measures, 11,695.
Nasik: About 5,000 people left from dread of segregation, 13,832.
Segregation practically impossible, drives inhabitants away, 7043, 20,237.

Details of:

Ahmednagar City: 16,000 people left the place when city was evacuated, 24,358–9.
Ankleshwar: People leaving in numbers at the commencement of the outbreak from fear, 14,538.
Bangalore City: 40,000 people left the city, 3504–5.
Bangalore Civil and Military Station: 25,000 people fled, 2639, 2666.
Belgaum: 12,000 people left, being encouraged by the authorities to leave, 22,824.
Bhiwandi: 7,000 out of 14,000 people fled during plague, 14,549, 23,359.
Bombay City: Details regarding exodus, 26,079–91, 26,559–66.
Broach: About 18,000 people left the place, about 3,000 for camps near the town, the rest for other places, 15,502.
Calcutta: Graphic description of panic when it became known that the Bombay plague had reached the town, I. 467.
Cutch Mandvi: During the first epidemic people fled from the infected houses leaving the sick and dead, 13,494.
Daman: Large number of people left by land before Surat cordon imposed, 15,997–9.
Gadag: Flight of traders, the landowners remaining, 23,680.

EXODUS OF PEOPLE FROM PLAGUE-INFECTED PLACES—*cont.*

Karachi: Population reduced through both epidemics by over 25,000, 11,716.
Karachi: 25,000 people allowed to leave Karachi in January 1897, 11,130–6.
Mysore City: Exodus less than at Bangalore, but extent not determined, 24,977.
Palanpur: 3,000 or 4,000 people fled to villages around, 13,084.
Panjab: Difference between the census population and the number of people ascertained by the roll-call in the villages of the Jullundur and Hoshiaspur districts, 9940–4.
Poona Cantonment: Normal population, 24,000; reduced to 15,000 or 12,000 during plague, 10,903, 10,906, 21,314.
Poona City: Second epidemic, population reduced from about 118,000 to 60,000 or 80,000 by exodus, 21,782–4.
Risk that evicted people will go to other villages, 21,147.
Sholapur: People in easy circumstances the first to leave the town, 20,250.
Sholapur: About 35,000 people left the place, 20,245.
Sholapur: People left the town before proceedings taken for general evacuation, 20,237, 23,989.
Shopkeepers scatter on being evicted, but landowners do not, 5891, 24,067–14.
Surat: About 10,000 people left with passes, 24,461.
Surat: Population increased by 20,000 through influx from Bombay, 15,863.

Prevention of:

Concessions connected with inoculation have good effect in stopping flight at Bangalore, 2637–8.
Concessions given to inoculated prevented the running away at Bulsar, 16,291.
Exodus at Bangalore not checked by guarding roads and pass system, 2641–3.
Hubli: Inoculated remain in larger proportion than uninoculated, I. 399.
Hyderabad: Stringent measures adopted to prevent the people flocking to the district, 18,116.
Mysore: Lenient measures prevented flight, and consequently there was very slow spread of plague in the town and neighbourhood, 24,970–8.

Spread of Plague through:

Bangalore: Villages in the neighbourhood infected by refugees, 2669.
Dharwar: One-third of those who left the town encamped near it, but about 19,000 people must have scattered over the country and spread plague, 23,767–70.
Karachi: People left in great numbers in beginning of 1897, and carried infection to Cutch Mandvi, 3,708.
Neighbouring villages infected by people flying from plague in towns, 24,016.
Sholapur: Fifty-five thousand refugees infected every village between that town and Hyderabad, 5153.
Sholapur: Refugees from, spread plague, 23,338.
Sholapur: At least 20,000 people left, carrying the plague with them over the country, 5425, 23,332–8, 23,912, 24,016.

See Fear of Plague.

EXPERIMENTS ON ANIMALS:

Experiments on animals of no value, except on those of the same class, 27,370.
The test of the efficiency of a method should be made directly on the species of animal which it is intended to benefit, 26,515–22.

See Inoculation with Haffkine's plague prophylactic.

EYE:

Clinical Features in Plague:

Complications of the eyes a clinical feature of plague, 20,897–901.
Conjunctiva: hyperæmia of, a clinical feature of plague, 12,398.

EYE—*cont.*

Inflammation of the cornea a clinical feature of plague, 16,768.
Ophthalmia a clinical feature of plague, 10,215.

Infection through:

Infection by microbes entering the body through the corners of the eyes and nostrils, III. 42.
Infection entered through the conjunctiva in one case, 7211, 7215.
Infection through the mucous membrane of the eye, 20,530.

Sequel of Plague:

Complete disintegration of the orbits and disease of the eyes followed plague, 16,770, 16,822, 16,833, 20,896–901.

Sight, Loss of:

Loss of sight through careless handling of bubonic discharge, 17,587.

FÆCES:

Life of Bacillus of Plague in:

Bacillus of plague dies in 2½ hours in fæces, 3611.
Bacillus not recoverable from fæces after death, 1437.
Can only be found in the excreta of fæces and urine when they contain blood, 22,367.
Cannot be cultivated from fæces, 1436–7.
Found in fæces, 3556–64.
Negative results as to discovery of plague bacillus in four cases examined, and positive result in a fifth case where matter examined was almost pure mucus, 25,363–4.
Negative results as to discovery of plague bacillus in cases examined, 17,271.
Unsuccessful attempts at isolating the bacillus from fæces ascribed to the rapid growth of contaminating micro-organisms, 26,391.

See Excreta.
„ Rats, *discovery of bacillus in*, and *infection by.*

FAKIRS:

The fakirs at Bhiwandi remained entirely free from plague, 22,128–9.

FEAR OF PLAGUE:

Deccan Brahmans are very cautious with regard to plague, 14,367.
Fear, &c. of plague drove the people at Rohri from the suburbs into the date plantations, 12,079.
Fear of plague is growing on the people, 26,568.
Fear of plague shown in Ankleshwar, 14,566.
Fear of plague makes people neglect to dispose of their dead, 7,420, 9,895–8, 13,491, 18,569.
Fear of plague did not at first move people at Dharwar to take any steps, 1614.
Great fear of infection among the natives in the hills, 8829, 26,615.
Great fear of plague shown in Bangalore, 2625–6.
Native dread of plague, 9898.
People more afraid of plague officers than of plague, 15,130.
People showed much fear of the plague in the Panjab, 10,263.
People who are afraid of the disease most liable to be affected by it, 10,857.

See Exodus of people from plague-infected places.

FEMALES.

See Inoculation with Haffkine's fluid. *After Effects, Bars to Inoculation* and *Dosage.*
„ Sex.
„ Pregnancy.

FEVER, RELAPSING:

See Relapsing Fever.

FLEAS:

Fleas, no plague microbes found (Hankin), 8600.
Fleas in Bombay hospitals do not convey infection, 20,640, 20,999.
Fleas in the plague infected villages of the Kaira district, 14,081.

FLEAS—*cont.*

Fleas, plague microbes said to be found in, 151.
Fleas, independent of plague, Baroda noted for its colonies, 14,642.
Fleas and bugs possible agents for carrying infection, 9,500–4.
No evidence that fleas carry infection, 20,640.

LIGHT OF PEOPLE FROM PLAGUE-INFECTED PLACES.

See Exodus of people from plague-infected places.

FLOORS:

Disinfection of:

Ahmedabad: Digging up of floors resorted to as disinfecting method, 13,923.
Ammonia and albumenoid substances in floors hindrances to chemical disinfection, 20,217–20.
Bacillus of plague survives disinfectants in infected floors, 5159.
Danger in digging up floors minimised by whitewashing it, 5554, I. 456.
Dharwar: No plague after ventilation, &c., of dug-up floors, 23,778.
Experiments on best method of disinfecting floors, II. 10–3.
Experiments on effect of perchloride of mercury on infected floors, 18,828–63.
Experiments showing that the number of micro-organisms in floors is less after than before disinfection, 18,801–27.
Guntakal: Upper two inches of floor dug up and burnt to disinfect, 5117.
Jawalapur: Digging up of floors, 8934.
Khandraoni: Floors dug up, 9659.
Mud floors very difficult to disinfect, 8558.
Palanpur: Digging of floors resorted to as disinfecting measure, 13,091–4.
Panjab: Taking up the floors of infected houses a dangerous and expensive process, but resorted to, 10,039.
Rohri: Disinfection by digging up floors, 12,029.
Stone floors much easier to disinfect than cow dung, 8269, 8562.
Stone floors cannot be removed for disinfection, 6442.

See Burning.
,, Cow-dung.
,, Kiln burning.
,, Perchloride of mercury.

Infectivity of:

Bacillus of plague on aerobic species cannot live far under the surface of floors, 10,040.
Bacillus of plague extends to a certain depth by growth, 11,457.
Bacillus of plague generally located in floors and walls, 9682.
Bacillus of plague may be disseminated by rain and carried into buildings by soil adhering to the feet, 6900.
Cases frequent in those who sit on the ground, 5097.
Eating food in infected localities off the ground, a cause of infection, 18,108.
Fact that women are, as a rule, more affected by plague than men would point to the floor as seat of infection, 16,216.
Floor, infection confined to, 23,249.
Floor one of the only factors which has proved infective, 21,717.
Floors principal source of infection, 24,311.
Floor probable medium of infection, 9617.
House with pukka floors remained immune, while cases frequent in houses with earthen floors, 19,442.
Houses with cemented and tiled floors less attacked than houses with mud floors, 22,650.
Infection spread by earth and cowdung floors, 21,725.
Infection thrives better in houses with mud floors than with stone floors, 16,222–8.
Infection of plague mostly found in mud houses, 10,373.
Instance to show greater infectivity of mud floors, 17,288–91.
Parsee houses, Poona, plague cases mostly on ground floors, 25,244.

FLOORS—*cont.*

People living in huts and on ground floors of mud are more susceptible than those living in the top floors of wood, 19,100.
People who live in upper stories escape most, 18,569.
Plague cases in Bombay tabulated according to the floor on which they occurred, 916.
Plague cases not so numerous in upper as lower floors of chawls in Bombay, 2784, 28,422.
Poona: Most cases on ground floor, which are more crowded and worse ventilated than upper floors, 21,519–22.
Practically no stone, wooden, or concrete floors in Poona, 12,730.

See Beds.
,, Boots.
,, Habits of the people affecting liability to plague.
,, Soil.

FLYING COLUMNS:

Composition of the flying columns, organised to carry out disinfection in places where special staff was urgently required, 16,992.
Organisation of flying columns, 17,158–9.
Staff and duties of flying columns, 21,618–29.

FOOD:

An acid re-action in articles of food kills the bacillus in a very short time, 8544, II. 7.
Infection by the alimentary canal is possible, 7076, 7211.
Natives may be infected by eating food directly off infected ground, 18,108, 22,021.
No post-mortem evidence of infection by the alimentary canal or stomach, I. 368, I. 375.

See Mahamari: *Food and Grain and Mahamari.*

FORMIC ACID:

Result of experiments, II. 7.

FORMS OF PLAGUE:

See Atypical forms of plague.
,, Bubonic plague.
,, Bullæ.
,, Clinical features of plague.
,, Pestis minor.
,, Pneumonic plague.
,, Post-mortem appearances in plague.
,, Septicæmic plague.

FOWL.

See Birds.

FUMIGATION:

Fumigation with resin and sulphur in Daman native villages used as a disinfecting measure, 25,448.

See Sulphur.

FUNERALS:

Backergunge: Cases of plague contracted by attendance at funerals of pneumonic patients, 7331–9, 8463–9.
Baroda, Gungaur: Epidemic due to attendance at the funeral of a pneumonic patient, 15,182–5.
Bombay: Three or four friends of a man, dead of plague pneumonia, got plague by attending his funeral, 18,212.
Bombay: Plague contracted from contact with the corpse of a pneumonic patient, 19,099.
Calcutta: Funerals are powerful features in spreading the plague, II. 538.
Clothes distributed at a funeral might be calculated to spread plague, 9802.
Hubli: Woman with plague at Hubli in February 1897 contracted it by attending a funeral in Bombay, 2396.
Kakhindi: Plague due to attending a funeral, 19,513.
Sirohi: Spread of plague after attendance at funeral of first patient, 9702–9, 9794–802.
Surat: Plague brought to Umra by people who had attended a plague funeral elsewhere, 2054.
Surat: Plague kept alive in camps because people got infected at funerals and gatherings to lament over the dead, 24,441.

FUNERALS—*cont.*

See Acharj.
,, Corpse bearers.
,, Domes.
,, Habits of the people affecting liability to plague.

GANCHI:

First cases of plague at Ankleshwar among the Ganchi, 14,209.
Houses of Ganchis in Surat very dirty: Sunars fairly clean, 2048.
Mortality in Government health camp accounted for by it being occupied by Ganchis, who hired themselves out as corpse bearers, 24,422.
Severe outbreak among the Ganchis in Surat, 2047.

GANJA:

Immunity of ganja smokers from plague, III. 43.

GARHWAL:

See Bombay: *Introduction of plague into.*
,, Mahamari and Sanjar.

GEOLOGICAL CONDITIONS AND THEIR RELATION TO PLAGUE:

Alluvial Soil:

It is doubtful whether alluvial soil is favourable to plague, I. 378.

Black Soil:

Chemical composition of black cotton soil, 8324.
Plague rages most fiercely in black soil, 23,649.

See Evacuation: *The rains and their Effect on Evacuation.*

Deccan Trap:

Plague cases almost entirely over Deccan trap and crystalline rocks; rare in alluvial belt, I. 295.
The connection between Deccan trap and plague merely due to infection spreading from Bombay over neighbouring part of the country of this formation, I. 295.

Geological Formation of Plague Areas:

Description of geological formations of the plague-stricken areas, I. 294–6.
No proof that geological formation has any effect on plague except by its physical formation, 8311, 8326.
Rocky and sandy soil and climate of Hyderabad Sind favourable for combating plague, 18,142.
Something in the environment of Calcutta inimical to the spread of the plague in epidemic form, 7627.

Laterite:

Laterite-supporting rocks coincide with chief plague areas, 8315.
Plague practically occurs in all soils of India and at present in the soil directly covering laterite, 8317–8.
Water passing through laterite would dissolve iron, which may be favourable to pathological organisms, 8319.

Porous Soils:

Medical opinion holds that porous soils are favourable to the spread of epidemics, 8326.
Porosity of the soil has probably some connection with plague, 8311.

GLANDS:

Clinical Features of, in Plague:

Description of typical bubo, I. 379.
Diffused discolouration over the bubo and ecchymosis underneath the skin in plague patients, 9573.
Mumps in early stage sometimes resemble buboes, 10,235.
Necrosis of; four instances, two recover, 6940.
Suppuration generally occurs, 2371.

Diagnosis of Plague:

Bubo alone not sufficient, 7530.

See Pneumonic plague: *Clinical features.*
,, Septicæmic plague: *Clinical features.*

GLANDS—*cont.*

Disappearance after Death:

Cases of bubonic plague in which the bubo disappeared after death, 20,010–6.

See Corpse inspection. *Efficacy of Corpse inspection in identification of plague.*

Discharge, Character of:

Loss of sight through careless handling of bubonic discharge, 17,587.
Peculiar character of the slough, 20,733.

Discovery of Bacillus of Plague in:

Found in bubo during life, 7189.
Found in bubo, spleen, liver, and lungs of plague corpses, 7189.
Found in enormous numbers in buboes, I. 370.
Found in glands, kidney, spleen, liver, and blood, I. 370.
Found in the bloody discharge from the nose in patient with sub-mental buboes, 26,259.
Gradually disappears from bubo as soon as suppuration sets in, 20,613.
Invariably recovered from buboes before suppuration has taken place, but none after, 25,370.
Not extracted from pus of bubo, 1530.
Not found in pus of buboes, 1,530.
Other than plague bacilli found in pus from buboes, 26,265.
Plague bacilli not found in lymph of bubo in patients whose temperature had gone down, 26,396.

Fatality with reference to:

Cases with multiple buboes generally fatal, 14,853.
Fatal forms of plague do not develop buboes, 10,199.
Sixty per cent. of multiple bubo cases recovered among the inoculated, 14,997.

Frequency of:

Bubonic cases represent about 75 per cent. of the whole number of cases, 9389.
Enlarged glands without pronounced plague a common occurrence among plague workers, 18,065.
German Plague Commission report cases of swollen glands unknown to patient, 7003.
Lymphatic glands enlarged in about half the cases of primary carbuncles and buboes, 12,487.

Number in Plague:

Generally one; highest number seen, 17, I. 370, 2368.

Position of:

Axillary buboes represent about 14 or 15 per cent. of the total cases, 9389.
Glands, affected by proximity to spot of entry of infection, 1410.
Glands directly related to the seat of inoculation, bubo not necessarily situated in the group of, 9566.
Groin, generally in the, 298.
In buboes of the neck local lesion generally found on the surface of the tonsil, 11,580.
Notes on the relative frequency of the buboes in different situations, 12,395–6.
Observations on the appearance and position of buboes in the patients of the Sassoon Hospital, 12,897.
Table showing the position of buboes in 3,128 cases, II. 95.
Table showing the site of the glands in 101 plague cases, II. 196.
See Inoculation with Haffkine's fluid: *After-effects—Buboes.*

Post-mortem Appearance:

Enlargement and injection of the mesenteric glands and enlargement of the epiploic vessels constant features in plague cases, 9549.
Lymphatic and mesenteric glands generally found enlarged in cases where no external buboes appeared, 10,419.
Post-mortem appearance of glands, 1419–20.

GLANDS—*cont.*

Prognosis of Plague:

Prognosis bad when cases with small buboes, 21,652.
Prognosis bad with slight glandular enlargement, which indicates fatal septicæmia, 6986.
Prognosis is good if the gland is confined to the femoral region, 13,025, 15,308, 16,544.
Suppuration of bubo a good prognosis, 1529.

Sexes, in:

In females mostly axillary, 18,051.
Women in C. Ward, Bombay, suffered more from axillary buboes than men, 18,049.

Time of Appearance:

Attack, during, may develop, 12,398.
Beginning of fever, have been noted before, 12,398.
Convalescent, may appear when patient is, 2,370.
Details of cases showing period between beginning of illness and appearance of buboes, 20,027, 20,032.
Early symptom, buboes a very, 10,204.

See Glandular fever.

GLANDULAR FEVER:

Bacteriological Examination:

Cultivations of the blood taken from hospital patients of the Shropshire regiment remained absolutely sterile, with one exception, where a strepto-coccus was found, 11,035.
Cultures from the blood of two men of the Shropshire regiment injected into rats and guinea-pigs produced no effect whatever, 26,859.
Microscopical examination for the malaria plasmodium in patients of the Shropshire regiment gave no result, 11,017.

Clinical Features of:

Cases with or without buboes common and long known in Calcutta with 40 per cent. mortality and not clinically to be differentiated from plague except, perhaps, by look of tongue and infectiousness, 8209, 8213–17, 8220–31.
Clinical features of glandular fever have nothing in common with those of bubonic plague, 6974.
Clinical record of cases of lymphatic gland enlargement in the military hospital, Mian Mir, 11,065.
Difficult to tell glandular fever from plague, 1161–4.
Fever and swollen glands possible apart from plague, 6958.
Glandular enlargements from causes other than plague not uncommon, 613–4.
Plague quite distinguishable from ordinary fever with swollen glands, 6975–9.
Several men of the Shropshire regiment ill with dysentery developed buboes, 11,023, 11,053–4.
Typical symptoms of, I. 521.

In:

Bengal: At certain times of the year people suffer from enlarged inguinal glands, ascribed to climatic influence, I. 488, I. 521.
Bengal: Glandular fever very common in poorly fed low caste natives, who are constantly exposed to malaria, 7636.
Bombay: Glandular fever is not plague. No cases seen during epidemic, I. 382.
Bengal: No bubonic fever resembling plague in Bengal, 7322.
Calcutta: Cases of, may be found at any time, 8180, 8372–5.
Calcutta: Cases seen all amenable to treatment, 7846.
Calcutta: Appearance in 1858. Very fatal, 8107–8.
Calcutta: Details of cases of bubo and fever among the soldiers since 1894, 11,020.
Calcutta: Record of cases at Station Hospital, I. 495–6.

GLANDULAR FEVER—*cont.*

Calcutta: Seen every year from 1858 to 1898, 8114.
Mian Mir: Cases of glandular fever like those observed at Calcutta observed in Panjab, 11,050.
Navy: Cases of non-venereal bubo, I. 495, 27,005–8.
Poona: Many cases decidedly not plague, 7636.
Shropshire regiment: Cases of bubo and fever among the men at Calcutta during the summer of 1896 attributed to malaria, 11,017.

Infectivity of:

Non-infectious and non-contagious, 8121.

See Calcutta; *Plague in* 1898 and *Suspected cases of Plague in* 1896 *in Calcutta.*

GOATS:

Effects of Virus on:

Goats wasted away under repeated doses of plague virus, 133.
Secure local immunity after repeated dose of plague virus, 115.

Immunity from Plague:

Unaffected by plague, I. 378.

Serum of:

Serum of goats used for inoculation, 130–3.

GOLAS:

First detected cases in Umreth in the Gola quarter, 14,027.
Mortality in Government health camp accounted for by it being occupied by Golas who hired themselves out as corpse bearers, 24,422.
Refused to move to other sites, municipality too poor to apply the Land Acquisition Act, 24,459.
Spread the infection to the other quarters in Surat, 16,064.
Suffered most from plague in Surat, 16,108.

GRAIN:

Discovery of Bacillus of Plague in:

Experiments on, with several kinds of grain and seeds, II. 16–17.
Found in grain, I. 442.
Failure to isolate bacillus from grain, 619–20, 635, 995.
Not found in supposed infected grain bags, grain, &c., 635.
Series of experiments for the recovery of the bacillus from grain, 26,386.

Disinfected by Sun:

Grain sundried at Hinganghat to disinfect it, 6066.
Grain infected by the excreta of rats disinfected by exposing to the sunlight, 9409.
Grain exposed to the sun for six hours, 10,317, 10,935.

Infection due to:

Damaged grain source of contagion to rats, thence to men, III. 42.
Danger of infection through clothes, much less than through bags containing grain, in which rats would nestle, 994.
Dharwar Jail: Possible introduction of plague in grain, 2241, 2289.
Grain bought from infected Banniah's shop by woman; she got plague; no other source of infection traced, 23,005–7.
Grain is eaten unparched as well as parched, 9455.
Grain may be infective if infected by rats, 9399.
Grain stolen from a house evacuated by Banniahs; plague followed among the Mangs who stole it, 23,004.
Infection by grain, 23,004, 23,005, 13,814, 13,834.
North-West Provinces: Infection supposed to be imported at Kankhal by infected grain from Hardwar, 8774.

GRAIN—*cont.*

North-West Provinces: Jawalapur, possible introduction of plague by grain, 9153.
Possible introduction of plague at Reri, by grain and eatables brought from infected areas, 12,447.
Rats and grain somehow responsible for spread of plague in Bombay, 8277.
Rats, clothing, and some unknown agent in the retail grain shops spread plague, 11,278, 11,430.
Rotten grain suspected at Bombay, 54.
Theory that grain kept long generates the plague bacillus, 17,019–20.
Sholapur: Disease said to be due to importation of infected grain from Karachi, 1000.

See Mahamari: *Food and Grain and Mahamari.*

Infection not due to:

Grain not a factor in the dissemination of the disease, 16,316, I. 377–8.
Not through grain, 20,636.
Not carried by grain or articles of food, 7511.
Rats proved not immune by subsequent injection eat with impunity artificially infected grain, 635, 642.

Life of Bacillus in:

Bacillus not recovered after 7 days in grain artificially infected and dried, 26,386.
Dies in sterilised solution of rotten grain, 3669.
Experiments to show that the bubonic microbe derived from pure cultures perishes within 13 days after being added to specimens of grains and seeds, II. 17.
Results of experiments with several kinds of grains and seeds on life of bacillus of plague, II. 16, 17, 18.
Virulence of the microbe in grain only persistent for a few days, 8535.

GRAIN DEALERS:

See Banniahs and Traders.

GRANARIES:

See Banniahs and Traders.

GROWTH OF BACILLUS OF PLAGUE:

See Bacteriological characteristics of bacillus of plague.

GUINEA PIGS:

Discovery of Bacillus in:

Easily discovered in the bronchial contents of guinea-pigs in laboratory experiments, 27,341.
Found in the intestines of a guinea-pig, 27,336.

Involution Forms of Bacillus of Plague in:

Involution forms of plague bacilli seen after death at the seat of inoculation in a guinea-pig, 26,227.

Post-mortem Appearances:

Greater variety in those of guinea-pigs than in those of rats, 26,409.

Virulence of Bacillus of Plague in:

Virulence of bacillus of plague increased by a series of intra-peritonial passages through guinea-pigs, 26,434.

GUNNY BAGS:

Discovery of Bacillus of Plague in:

Microbes not found in sacks or other article of merchandise, 995.
None found in gunny bags in the Joria Bazar at Karachi, 11,210.
Not found in, 635.
Rats proved not immune by subsequent injection, eat with impunity supposed infected bags, 635–642.
Series of experiments for the recovery of the bacillus from artificially infected grain and gunny bags, not recovered after seven days, 26,386.

Disinfection of:

Grain, sun-dried at Hinganghat, and the bags boiled, 6066.

GUNNY BAGS—*cont.*

Gunny bags imported from infected places sent to Kiamari camp for disinfection by steam, 12,017.
Only cargo subject to disinfection at Karachi are the gunny bags which are sent back empty, 12,212.

Infection by:

Bhujpur: Infection said to be imported in gunny bags from Bombay, 13,462–71.
Idea that bags carry infection through rats, and that Karachi was infected by them in the second epidemic, 817.

HABITS OF THE PEOPLE AFFECTING LIABILITY TO PLAGUE:

Habits connected with Animals:

Jains and Banniahs averse from killing any animal or insect, 13,354.
Jains: Animal life sacred among the, 17,681.
Jains averse from anything involving the death of an animal, 7893.
Jains: High death-rate among, due to their refusal to destroy animals, particularly rats, 17,681.
Jains, Banniahs, and Marwaris will not take animal life, 17,741.
Jains, Banniahs, and others would sooner run the risk of plague than take animal life, 910.
Marwaris object to the slaughter of rats, I. 464.

Other Habits:

Attendance on sick: Natives kiss and wipe the mouths of plague patients, 13,013, 25,229.
Attendance on the sick: Plague spread by handling sputum, 17,785–18,511.
Attendance on sick: Spread by native habit of receiving patient's sputum into their hands, I. 379.
Attendance on sick: Sputum caught from plague patients in the hands of sympathetic friends, I. 408.
Barbers: Disease communicated by razors, hair-brushes, and aprons of barbers, III. 43.
Barbers: Infection through natives having their armpits shaved, III. 44.
Barbers use their razors for cutting the buboes of patients, 17,962.
Barbers who went to infected villages and brought clothes to their own villages introduced plague there, 10,051, 10,088.
Bare feet: Cracks on feet of natives common, 15,198.
Bare feet: Going barefoot, a common habit, is dangerous, 24,311, 24,349–51.
Bare feet: Infection through feet not common in North India, as no stones there to cut the feet, 9391.
Bare feet: Kumaun: No shoes or stockings generally worn, 26,573.
Bare feet: Kumaun: Shoes often not worn except in higher parts, 26,619–24.
Bare feet: Natives infected by their feet through cuts, 1002.
Bare feet: People go barefoot and have cracks in their skin, 532.
Bare feet: People go barefoot and sit on the ground, 17,370.
General remarks on influence of habits, 17,681–6.
Ground: Cases frequent in those who sit on the ground, 5097.
Ground: Infection by food in infected localities eaten off the ground, 18,108, 22,021.
Ground: Natives sit with their hands on the floor, and have many scratches and lesions by which infection may enter, 20,644.
Infection by mud used for cleaning purposes after deeds of nature, 18,113, 25,778.
Infection by mud used to clean brass vessels: cleaning with infected earth may communicate plague, 18,049, 18,112.
Infection by visiting the sick, 19,369.
Infection through funeral ceremonies, 17,993.
Infection through certain remedial ceremonies, 10,104.

UNIVERSITY OF EDINBURGH INSTITUTE

HÆMORRHAGES:

Clinical features:

Hæmorrhages in the bowels and stomach, 20,854.

Post-mortem Appearance:

Description of internal hæmorrhages, 6898.
Hæmorrhage in every part of the body, 20,972.
Small hæmorrhages in Peyer's patches seen in two cases, 6899.

Prognosis:

Sign of bad prognosis in plague cases, 12,413.

HAFFKINE'S CURATIVE SERUM:

Experiments on Animals:

Animals favourably affected by serum treatment, 135.

General Statement about:

General statement regarding method of preparation and trial of Haffkine's serum, 128–42.

Inefficacy:

Arthur Road Hospital: Serum treatment ineffectual, and at Poona and Bombay, 133, 140–1.
Byculla Jail: Cases treated with Haffkine's serum; mortality 50 per cent.; results unsatisfactory, 17,043–51.
Four cases treated with Haffkine's curative serum; all died, 19,113.
Only on one occasion, in Byculla Jail, in the treatment of six patients was the serum treatment applied with favourable result, 133.
Only one case in which the course of disease was favourably influenced by treatment with, 130–3.
Opinion that Haffkine's curative serum failed 19,041.

HAFFKINE'S PLAGUE PROPHYLACTIC:

Arranged under the following subheads:

Character and preparation of Haffkine's fluid.
Constituents of Haffkine's fluid.
Re-sterilisation of Haffkine's fluid.
Sterility of Haffkine's fluid.

See also, Inoculation with Haffkine's Plague Prophylactic, *under which the entries are given under the following subheads:*

Adoption of Inoculation as a general Plague Measure.
After Effects of Inoculation with Haffkine's Fluid.
Age and Inoculation.
Animals, Experiments on.
Attitude of People towards Inoculation.
Bars to Inoculation with Haffkine's Fluid.
Caste, Religion, and Race; Inoculation with reference to.
Certificates of Inoculation.
Dosage.
Duration of Protection afforded by Inoculation.
Effects of Inoculation with Haffkine's Fluid—
Attacks; on Plague—
Clinical Symptoms of Plague; on—
Incubating Plague; on—
Mortality; on Plague—
Other Diseases; on—
Spread of Plague; on—
Extensive Application of Inoculation: when resorted to and General Effects of.
History of Inoculation in particular places.
Identification of Bodies of Inoculated Persons.
Inducements to Inoculation with Haffkine's Fluid.
Investigation Sheets.
Method of performing Inoculations.
Period for which Protective Effect exerted.
Persons recovered from Plague; Inoculation of.
Reaction after Inoculation of Haffkine's Fluid.
Registration of Inoculated Persons and Statistics regarding Inoculation.
Re-inoculation.
Standardisation of Dose.
Strength of Haffkine's Fluid.

HAFFKINE'S PLAGUE PROPHYLACTIC—*cont.*

CHARACTER AND PREPARATION OF HAFFKINE'S FLUID.

Consists of a transparent fluid and a solid residue of dead microbes, 27.
Cultures made with microbes of varying virulence, which is not tested, 17,418–22, 17,425.
How decanted and sterilised, I. 345.
Is sterile at the time it is being decanted, 17,274–87.
Method of testing the bottles in laboratory, 17,476.
Might be cultivated on papaya, to meet Jains' religious scruples, 7895.
Preparation of, 26–31, 99–109, 1. 345.
Requires great care for cleanliness, 919.
Rules for decanting the fluid, 17,456–67.
Specimen labels on bottles, 4577.

CONSTITUENTS OF HAFFKINE'S FLUID.

Experiments for determining the toxic element of the supernatant fluid would point to its being contained in the carbolic acid, III. 141.
Mr. Haffkine unwilling to eliminate the supernatant fluid until exact observations on men show such a modification to be admissible, 26,516.
No facts from experiments made on animals to show that the supernatant fluid is of use in providing immunity, 26,526.
Relative toxicity of peptone broth and of filtrate from plague culture, III., 345.
Results of experiments to determine the respective protective power of the sediment and supernatant fluid, III. 342.
Sediment: Amount in the bottles, details of experiments to determine the, 26,272.
Sediment: Weights of, in a prescribed dose, table showing the different, III. 335.
Sediment: Weighing of, not considered a satisfactory method for standardising the fluid, 26,473.
Supernatant fluid: 20c.c. minimum lethal dose for animals, 26,380.
Supernatant fluid was introduced into the prophylactic in order to reduce the fatality of attacks in the inoculated, 26,507.
Table of respective immunising power of Haffkine's nutrient medium and prophylactic, III. 343.
Table showing experiments on relative immunising power of Haffkine's nutrient medium, and of filtrate of culture of plague grown in that medium, III., 345.
Tables showing the results of tests to determine the toxicity of the sediment and supernatant fluid, III. 341.

RE-STERILISATION OF HAFFKINE'S FLUID.

Experiments for resterilising vaccine by heat gave satisfactory results, 24,917–21, 29,926–31.
Experiments on rabbits with re-sterilised fluid more satisfactory than with fluid as received from Bombay, 24,602–30.
Re-sterilisation at 60° C. for a quarter of an hour for three consecutive days killed the organisms in the prophylactic fluid, 24,670.

STERILITY OF HAFFKINE'S FLUID.

Contaminated:

Animals: Eight out of 38 died from the effects of inoculation of the prophylactic, which was found to be contaminated, 24,589–601.
Bacteria seen in fluid, but not motile, and no growth obtained, 6310–8.
Cocci found in, brown and white, 5298.
Fungus appearance, one bottle of Haffkine's fluid rejected out of 300 on account of the contents presenting a, 14,805.
Impurities found in fluid, I. 460.
Impurities found in seven bottles out of 25, 8381.
Many doses returned as not good, 1809.
Micro-cocci and occasionally bacilli, fluid contains, 5680.
Micro-cocci, stained preparations from six bottles of Haffkine's fluid showed, 10,659.
Micro-organisms in fluid appear to give a certain amount of immunity, 5708.

HAFFKINE'S PLAGUE PROPHYLACTIC—*cont.*

Micro-organisms are cultivated from five out of six bottles, 5804.
Micro-organisms found in two out of 12 bottles of Haffkine's fluid, 10,653.
One bottle out of six from Hyderabad contains impurity, 8405.
Organisms found in each of the 24 bottles tested, 5387.
Organisms, three out 12 bottles tested contained, but none the bacillus of plague, 26,376.
Organisms, the contents of six properly-sealed bottles left to grow at the natural temperature of the room showed a growth of living, 5811.
Plague bacilli, objections to the prophylactic on the ground that it contains living, 18,663–727.
Putrefaction, Haffkine's fluid liable to, 19,319.
Putrefaction in most bottles, slight smell of, 5805.
Putrescent fluid, tests to verify the assertion that the prophylactic is a, 17,908.
Putrescent organic liquid, 5161.
Pyogenic cocci found in, 5299.
Rabbits, no result from injection of organisms from into, 5314.
Smell not a sound test for purity of, 8415–6.
Several bottles of Haffkine's fluid rejected because contents smelt of fish, 16,566.
Septic organisms, the fluid as received from Bombay was examined and proved to contain, 24,890.
Two bottles of bad fluid seen, 7884.
Two bottles returned, 1837.
White precipitate found, 6305.

Non-contaminated:

Found in uniform good condition at Belgaum, 5629.
Fluid in bottles still sterile six weeks after first use, 6823.
Less than one per cent. rejected by Captain Leumann, 3014.
Never found putrid, 10,159.
Never obliged to reject Haffkine's fluid on account of its being impure, 16,279.
No living organisms found in fluid, 6563.
No recognised organism of disease found, 8386.
Sterile at the time it is being decanted, 17,274–87.
The purity of the fluid lately improved, 24,646, 24,917.
Very few bottles rejected, 1781.

Experiments to test Sterility:

Bottles tested at Bombay, 26,375.
Cook's samples sterile, 6567.
Experiments by Captain Johnston, I.M.S., 5798–821, 24,895–916, App. LXX.
Experiments on purity of fluid, I. 211.
Fluid tested after sterilisation and carbolisation. 17,471.
In experiments in Mr. Haffkine's laboratory the carbolic in the fluid not diluted, 17,302–6.
Report on examination of Haffkine's fluid, 15,388–92.
Results of bacteriological examination of Haffkine's fluid at Calcutta, 8380–9.
Results of examination of old bottles of prophylactic in Haffkine's laboratory, 17,481.

See Rabbits.

Sterilisation by Carbolic:

Carbolic acid added to culture to sterilise it, 105.
Carbolised vaccine first used in Lanauli, 65.
Plague bacillus cannot possibly live in the fluid, because of the carbolic acid, 8411.
Probably affected by heat but not by carbolic, 119–20.

Sterilisation by Heat:

How affected by heat, 109, 119.
Sterilised by one hour's heating to 65 C., 104.
The culture dies at 45 C. 102.

Sterilisation, Importance of:

The use of a microbe of known virulence and an absolutely aseptic vaccine the necessary factors in, 26,488.

HAFFKINE'S PLAGUE PROPHYLACTIC—*cont.*

The use of a perfectly sterile vaccine and of a dose definitely known, the most important points in every vaccination, 26,449.

HANKIN'S METHODS OF SEARCH FOR THE PLAGUE BACILLUS:

Description of method, 8552, (II. 8), 8594–8603.
Hankin's method not a reliable test for detecting the plague bacillus, 26,130.

HARDWAR.

See North-Western Provinces, *places infected in.*

HEALTH OFFICERS:

Each district should have a Health Officer. 8002.
Great improvements in the general health of the N.W. Provinces, since the appointment of Health Officers, 8973–9.
Health Officers not necessarily members of the Indian Medical Service, 7939.
Health Officer might with advantage report to Sanitary Board, 7804–5.
Health Officers appointed by Municipality, 7937.
Health Officers only in large Municipalities, 7795.
Position of Health Officer in Municipality purely advisory, 7796, 7937.
Power of Health Officer in plague matters absorbed by Plague Committee at Poona, 21,834.

HEAT.

See Hot weather.
„ Period for which plague bacillus can survive.

HIDES.

See Merchandise.

HISTORY OF INOCULATION IN PARTICULAR PLACES.

See Inoculation with Haffkine's plague prophylactic.

HORSES:

Immunity:

Secure local immunity after repeated doses of plague virus, 115.
Unaffected by plague, I. 378.

Serum of:

Serum of horses used for therapeutic inoculation, 130–3.

See Lustig's serum.

HOSPITALS:

Attitude of the People towards:

Bangalore: Very unpopular, 3282.
Bangalore: People thought Government were poisoning patients in hospital, 2628.
Bombay: Arthur Road Hospital threatened with destruction by the populace, 26,638.
Bombay: Patients go more readily now to hospital, 444, 7863.
Bombay: People had no belief in hospitals, 17,950.
Calcutta: Manicktollah Hospital, patients will not go to, 7717.
Calcutta: Natives say they are not properly treated at Manicktollah, 7722.
Calcutta: Patients go fairly readily to Mayo Hospital, 7717.
Calcutta: Very friendly relations with relatives of patients, 6966.
Dharwar: Patients come readily, 1863.
Dread of Government hospitals and of being carried there on stretchers, 22,656.
Hardwar: Great objection of the natives to go to hospitals, 8800.
Hindu notions averse to taking people to hospital, 22,581.
Karachi: People voluntarily brought sick to hospital huts in camps Trans Lyari, 11,246.
Mortality in hospitals the reason for their unpopularity, 26,550.
Muhammadans rather troublesome in hospitals, 13,532.

HOSPITALS—*cont.*

Objection to hospital from fear of being poisoned, 18,574.
Poona: Relatives willing to send patients to hospital as soon as definite symptoms of plague develop, 25,842.
Preponderance of males in hospitals partly due to the objection to bring the females there, 12,347.

Caste Prejudices and Caste Hospitals:

Bangalore: Caste prejudices respected as far as possible, 3483.
Calcutta: Caste prejudices respected in hospital, I. 471.
Cutch Mandvi: Caste hospital much approved of by the people at, 13,443.
Cutch Mandvi: No difficulty to get people to caste hospitals, but considerable objection to be taken to Government hospitals, 27,191.
Surat: Caste prejudices considered in the Hindu Hospital, 16,137.
Surat: Concealment punished in Surat by removal to general instead of caste hospital, 24,417.

Friends and Relatives of Patients, Arrangements for:

Broach: Families should never be separated in hospitals; good results of system, 15,500.
Dharwar: Friends allowed to stay with patients if they like, 1867.
Each hospital should have a house attached for some of the friends of patients, 21,544.
Friends encouraged to come to the hospital with the sick, 6963.
Hubli: Friends allowed to accompany patients to hospital, 1656.
Poona: A friend of the patient taken to hospital with him, 10,915, 21,259.
Surat: Accommodation for friends of patients in Hindu Hospital, 16,137.

Infection in:

A properly made plague hospital does not require disinfection every time a patient dies, 19,515.
Attendants and friends of patients escape the disease in hospitals because they are under much better hygienic conditions, 14,713.
Bangalore Civil and Military Station: Of 16 attendants and ayahs, four got plague, 2737–8.
Bangalore Civil and Military Station: Friends of patients allowed to accompany them and attendants do not suffer, 2897–900, 2922–3, 3483.
Bombay: Arthur Road Hospital: very few attendants attacked, 20,973, 20,989.
Bombay: Cases among attendants at Bombay, 7218–9.
Bombay: No cases noted of infection of hospital servants by Major Deane while in Bombay, 2789.
Bombay: No disinfection at first of plague cases in Jamsetjee Hospital, Bombay, but no bad results, 1439, 1516.
Bombay: Staff and attendants not often infected, 22,489.
Broach: No infection in hospital, 15,500.
Calcutta: Antiseptics used but particular precautions not taken by nurses, 7083, 6961–2.
Calcutta: Disinfection carefully attended to, 7022.
Calcutta: Medical College Hospital not an ideal place, ventilation leaves much to desire, 7082.
Calcutta: No infection in the Medical College Hospital, 6921, 6961.
Calcutta: No infection among 74 servants in the Chandni or Mayo Hospitals, 7020.
Calcutta: No infection in the Medical College Hospital, 7081.
Clothing destroyed and no further infection in Bangalore Hospital, 2894.
Clothing disinfected in Anand Hospital by steam, 14,127.
Clothing not very infectious to hospital attendants, 237.
Contact with plague patients in plague hospital said to be means of conveyance of plague, 19,031.

HOSPITALS—*cont.*

Cutch Mandvi: Fourteen plague nurses working in Mandvi Hospital during first epidemic; very few casualties among the attendants or relatives, 13,527, 13,533–6; I. 351.
Dharwar: 30 relatives attending on patients developed plague, and two bubonic and four pneumonic cases occurred among hospital staff; pneumonic infected from pneumonic cases; bubonic not from pneumonic cases, as there were none such in hospital at the time of their infection, 1896–1901.
Dharwar: Attendants on the sick not very often attacked, 1953.
Freedom from infection due to good sanitary conditions, 1440–1, 10,376.
Gadag: Hospital staff and attendants not infected; cases that occurred contracted outside, 23,684–91, 23,757.
Hubli: Few cases amongst hospital attendants at Hubli and Dharwar, 1704.
Panjab: Hospital attendants usually not attacked, 10,488.
Patients spit about everywhere, 20,628–7085.
Plague cases among doctors, 7220.
Plague cases among nurses, 7220, 7661.
Plague mortality among those connected with hospitals, 7220.
Poona: People in hospitals free, disease not very infectious, 12,876–7, 12,937, 21,539.
Porbandar: Few cases in hospital, where only six pneumonic cases treated, 13,724–7, II. 484.
Sirohi: Few cases among attendants and plague officials, 9878–80, 9906–9.
Sirohi: High mortality among the sick attendants accounted for by their being in incubation stage on arrival at hospital, 9907.
Surat Government Hospital: Few attacks among staff and attendants, 15,792–6.
Surat: One-fourth of the staff and attendants in the Hindu Hospital were attacked; no shoes were worn, the floors were bad, and disinfectants not properly used, 15,797, 15,825.
Surat: Only 19 cases among 1,200 relations of patients in the Hindu Plague Hospital, Surat, 16,149.
Umreth: No deaths among the attendants in the Plague Hospital or the village hospitals, II. 233.
Very slight infectiousness in a properly kept hospital, 1439.

Mortality in Hospitals:

Ankleshwar hospitals: table showing, with results, admissions to the, II. 246.
Bangalore City: 66.7 per cent., 25,024.
Bangalore City: Statistics regarding, 3483.
Bangalore Military Hospitals: 71·4 per cent., III. 286.
Bangalore, North Camp Hospital: 63·4 per cent., 25,024.
Bangalore, South Camp Hospital: 60·2 per cent., 25,024.
Baroda: 71 per cent., 15,266–8.
Bombay, Arthur Road: 71·4 per cent., 21,050, III. 457.
Bombay: Arthur Road and Parel Hospitals, I. 391.
Bombay: Arthur Road Hospital: Statistics of cases treated from September 1896 to February 1899, III. 457–60.
Bombay: Parel Hospital, I. 257.
Bombay: Statement showing number of plague patients admitted to all plague hospitals, public and private, from March 1897 to March 1899, III. 313.
Calcutta: 80 per cent., 6550.
Calcutta: Mayo Hospital, description of plague cases in, 7015.
Calcutta: Medical College Hospital, I. 244.
Dharwar Hospital: Case mortality, 58 per cent., 1857.
Gadag: Statistics relating to, 23,694–5.
Karachi Civil Hospital: From March till August 514 cases treated with a mortality of 60 per cent., 12,342.
Mysore: 49 per cent., 25,024.
Poona, Sassoon Hospital: 74·4 per cent., 12,896.
Umreth Plague Hospital: Forty-eight deaths out of the 64 cases admitted to, II. 233.

HOSPITALS—*cont.*

See Medical treatment, European.
,, Removal of the sick to hospital.
,, Removal of moribund patients to hospital.

Private Hospitals:

Ahmedabad: Private hospitals established, 13,890.
Bombay: Private local hospital started in the Telang property whilst the blocks were disinfected, 17,865.
Calcutta: Large number raised by private subscriptions, and licensed, I. 469.
Calcutta: Particulars of private hospitals, I. 470.
Calcutta: Private hospitals little resorted to, II. 533.
Karachi: Private hospitals started by several communities, 12,523.
Porbandar: Hospitals started by private persons, 13,702.
Private plague hospital and segregation camp popular with the people, 12,522.
Surat: Hindu Hospital maintained entirely by private contributions, 16,137.

Provision, Organisation, and Staff of Hospitals:

Ahmedabad, list of plague hospitals, 13,890.
Anand: Plague hospital built of millet seed stalks, lined with bamboo matting which was whitewashed, 14,111.
Bangalore: The details of the camp hospitals at, I. 117–9.
Bombay: Hospital arrangements, accommodation for 1,000 cases, 251–71, 276–84, 417–8.
Bombay: Nursing poor at first, now satisfactory, 259.
Bombay: Organisation satisfactory, 250.
Bombay: Very inadequate staff in plague hospital, 25,508–32.
Calcutta: Arrangements for hospitals in different wards of the town, 6756.
Calcutta: Manicktollah Hospital, description of, I. 469.
Dharwar: Staff (beds 76), 1852, 1854, 2068, 2071.
Hardwar: Old temple used as plague hospital, 9332.
Igatpuri: Municipal school turned into hospital, 16,887.
Inspector-General of Civil Hospitals not responsible for supervision of municipal hospitals, 276–8.
Inspector-General of Civil Hospitals responsible for inspection of municipal hospitals, 7742.
Plague hospitals should be located at a distance of at least half a mile from the town limits, 13,928.
Poona: Sassoon Hospital, special building for plague cases, 12,941.
Porbandar: Eleven plague hospitals, 13,702.
Rural areas: No hospitals in, 1661.
Surat: Native hospitals good at, 5.
Surat: Proper hospital system introduced by Lord Sandhurst, 16,137.
Surat: The Parakh Dharamsala turned into a municipal hospital, 24,417.
Sweepers and police on duty at the plague hospitals at Hardwar relieved every 10 days, 9337.
Tents as hospitals better suited for cold than hot weather, 12,943.
Ward hospitals more suitable than one central plague hospital, 21,544.

HOT WEATHER:

Abatement of Plague during:

Ahmedabad: The dryness of the atmosphere probable cause of partial evacuation proving there more successful than at other places, 13,937.
Bombay Presidency: During the hot season the plague declined in, 2.
Broach: The habit of the people to sleep outside their houses in hot weather the reason why plague has remained dormant in May and June, 14,385.
Heat prevents plague from spreading fast, 5307.

HOT WEATHER—*cont.*

Hot winds appear to act as natural disinfectants, 8.
Hyderabad: The dry and very hot climate and rocky and sandy soil favourable conditions in combating the plague, 18,142.
Kolaba: Plague occurred in each of the infected towns in, in the cold weather, and dropped as the hot weather came on, 17,650.
Panjab: In hot weather plague becomes milder in type, 10, 332.
Plague decreases in hot weather, I. 378, 1035.
Sirohi State: Relation between temperature and epidemic very marked in, 9902, App. XXXII.
Table of maximum and minimum temperature during epidemic in Baroda City, II. 283.
Temperature of 80° to 90° the predisposing conditions to plague, 17,354.
Temperature in Bengal before outbreak of plague below normal, 6874.
Variable temperature; a rise in the plague attacks coincides with a fall in the temperature, in places with a, 22,433.

Epidemic of Plague during:

Cutch Mandvi: Plague begins in hot weather, 2.
Hot weather seems to have no influence on the virulence of the epidemic, 25,682.
Kankhal: Plague did not spread in May on account of the hot weather conditions, people being much out in the open and sleeping out, 9071.
Karachi: Heat did not affect plague in, 1700.
Sukkur: Epidemic at its height when temperature was 115 degrees in the shade, 11,446.
Sukkur: Rise in temperature no influence on the disease in, 18,441.
Temperature: Has nothing to do with plague epidemics in India, 11,444.

HOUSE.

See Disinfection.
,, Evacuation: *Length of period of evacuation.*
,, Floor.
,, Incubation period: *Incubation period in plague cases contracted by visits to infected places and houses, or contact with the sick.*
,, Infection by locality.
,, Soil.
,, Recurrence of plague in the same house or locality.

HOUSE SEARCHES:

Adoption of and Experience in:

Ankleshwar: House to house visitation gave good results, 14,218–9.
Bangalore City: House searches not adopted on account of the attitude of the people towards them, 3279.
Bangalore Civil and Military Station: System of house searches adopted, 2572.
Baroda: House to house inspection at the commencement of second outbreak very unsatisfactory, 14,601.
Bombay: House to house visitation by native gentlemen unsuccessful, 17,954.
Bombay: On account of large chawls and shifting population house searching of little use, 16,987.
Bombay: Opposition during the first epidemic to search parties, 18,465.
Bombay: Raids only made at odd times in worst quarters, 10,949–51.
Bombay: Search parties resented in, and cases concealed, 487–9.
Bombay: Search parties with European agency resulted in plague being driven out of one district but only into another, 18,464, 25,794.
Bombay: System of house searching abandoned, 8257.
Cutch Mandvi: Search parties instituted towards the end of April 1897, 13,375.
Karachi: Search parties employed with good results in camps, though results in the town were bad, the people scattering, and no information being obtained, 11,370–2.

HOUSE SEARCHES—*cont.*

Kolaba: In the second epidemic no resistance offered to the search parties by the people, except in 5 Muhammadans' houses, 18,465.
Kolaba: Search parties were good friends with the people, as they never interfered with caste prejudices, 18,466.
Poona: House searches successfully carried out, staff strong enough to prevent concealment, 10,908–13, 21,216, 21,259, 21,269.
Poona: Second epidemic, house searching by volunteers with help of soldiers, 21,494, 21,526, 21,576.
Shikarpur: People induced to use precautionary measures to avoid search parties, 18,288.
Surat: House to house search of no practical utility, 16,004, 24,417.
Umreth: House to house visitation every morning, 14,039.

Agency for:

Karachi: Objection to use of military in, 12,527.
Palanpur State: Darbar Sepoys employed for search parties, 13,069.
Poona: Search parties of European and native soldiers employed, 10,908, 21,259.
Voluntary organisations for the detection of plague more successful than military search parties, 18,387.

Opinions and Recommendations regarding:

House to house visitation for discovering plague cases absolutely intolerable to the people, 25,554.
House to house visitation impossible without considerable annoyance to the people, 16,987,
In large places only possible methods are searching, &c., 10,963, 16,987.
Room to room visitation in tenements impossible on account of the irritation it would cause, 7619.
Search parties did more harm than good at Surat, 24,417.
Search parties do more harm than good, 18,978.
Search parties not a good thing, too unpopular, 8259.
Searching ought to be the last means resorted to on account of the objection of the people, 10,964.
Ward system with superintendence a better measure than search parties, 18,975.

HOUSING:

Existing Conditions:

Ahmednagar: Contains houses in which air and light had never had access since they were constructed ages ago, III. 253.
Ahmednagar: Number of houses condemned in, re-building on a particular pattern, ventilation, big doors, windows, and height of roofs specified, 24,191.
Bangalore: Overcrowding in houses, 3258.
Bangalore: Statistics of housing, 3386, I. 128.
Baroda: Dwellings insanitary, 15,193.
Belgaum: Description of houses in, 22,810.
Bombay: Conditions vary in different parts, 8295–6.
Bombay: Conditions very bad, 17,692, 26,638.
Bombay: Description of houses and difficulty of keeping them clean, 833–91.
Bombay houses: Practically no light, 851.
Bombay: Kamatipura, 70 per cent. of houses insanitary, 972.
Calcutta bustees more airy than Bombay chawls, 7439.
Calcutta: Bustees dreadfully insanitary, 7632.
Calcutta: Bustee houses very difficult to disinfect, 7689–91.
Calcutta: Construction of bustees, 7708.
Calcutta: Housing conditions, 6861.
Dharwar houses: No light, 1711, 2307.
Dharwar: Houses of the agriculturists in the villages are very dirty, ill-ventilated, and dark, 23,518.
Dharwar: Style of houses one-storied with bamboo roofs laid on beams covered with earth easily opened up, 23,175.
Dharwar: Ventilation and light very bad, 23,185.

HOUSING—*cont.*

Hardwar: Houses well built, well ventilated, and not overcrowded, 9005–7.
Hinganghat: No light or air in houses, 6249.
Hubli: Except for ventilation, houses excellent for an Indian City, 20,144, 20,207–10.
Hyderabad: Houses badly lighted and ventilated, 5446.
Kankhal: Houses very large and sparely occupied, except on the occasion of the Kumbh fair, 9013.
Karachi: Houses in old town very bad, 11,080–6, 11,971, 12,456–63, 22,649.
Kumaun: Sleeping rooms, for warmth, just over cattle stalls, and also used as store-room for grain, some of which is gathered wet, II. 354, 360.
Nasik: Description of houses, 13,786–8, 16,980–4.
Panjab: Description of houses, 10,370.
Surat: Houses of Ganchis very dirty; Sunars fairly clean, 2048.

Housing of Cattle:

All villagers inclined to keep cattle and manure close to their houses, 7922.
Baroda: Cattle and men live all under same roof, 15,193.
Cattle in one enclosure with living rooms at Pali, 6423.
Cows kept in filthy state in Kumaun dwelling-houses, 6163.
Cutch Mandvi: Cattle kept by the people of, in the lower rooms of the houses, 13,353.
Dharwar district: Kept in the dwelling-houses in all the villages in the, 23,180, 23,431, 23,518.
Housing of cattle in human dwellings a confirmed habit which cannot be altered, 7922.

Improvements in Housing:

Bangalore: Scheme for improving housing and rebuilding part of city, 3261, 3481.
Bombay: Houses marked unfit for human habitation and removed; number removed, 25,666.
Bombay: Improvements effected in respect of insanitary houses, 946–71.
Bombay Municipal Act is likely to improve the housing, 869.
Bombay: Re-building of houses proposed by Bombay Government at cost of four crores, 1101.
Bombay: Re-housing cannot be carried out at once, 965.
Improvements required in conditions prevailing within the houses, 8066.
Intended to destroy the worst houses, but this was found impossible, 26,682.
Poona: A considerable number of bad houses demolished, 21,290.
To secure light and air in houses, the whole of India would require to be rebuilt, 8067.

No Relation between bad Housing and Prevalence of Plague:

Bombay: Mandvi quarter, houses where plague broke out first roomy and airy, 19,437.
Bombay: Plague, though often found in insanitary houses, severe in many sanitary houses in Mandvi, 17,691.
Bombay: Plague infected houses in Mandvi, many of them good, 19,437.
Bombay: Several cases at Mandvi in well-lighted and well-aired rooms, 1512.
Calcutta: Bustee houses expected to be the scourge of the place have been its salvation, 7443.
Calcutta: Some cases in good houses; disease appearing in good or bad houses wherever the contagium morbi was carried, 6659–60.
Habitation and surroundings not the exclusive factors in giving immunity from plague, 6070.
Incidence of plague does not vary with character of house, 6285.
Poona: Infection for a time raged very high in houses on raised platforms with plenty of air and light, 21,583, 21,608–11.

HOUSING—*cont.*

Sholapur: Cases equally frequent in bad and better class houses, 23,959–62.

Relation between bad Housing and Prevalence of Plague:

Ahmedabad: Considerable difference between the houses in the chief plague-infected areas and the other areas, 13,975, 13,978, 13,980, 13,985.
Baluchistan: Unfit houses pulled down, plague does not come, 8096.
Bombay: Bad housing responsible for plague remaining, 8273.
Bombay: Plague occurred in bad houses; no plague in good houses, 26,638, 26,672–4.
Calcutta: Incidence of attacks in dwellings at, I. 4474.
Dharwar: Plague in bad houses, while well ventilated houses escaped, 2307–9.
Karachi: Really good houses in the worst infected parts of the city remained free, 22,649.
Karachi: The wretched construction of the houses in the market quarter, and their insanitary condition, enabled rats to spread the disease, 22,649.
Most cases where sleeping rooms badly lighted and ventilated, 19,515.
Nasik: Plague cases chiefly in dark, dirty, and badly ventilated, and overcrowded houses, 24,524.
Nasik: Plague not worst in worst quarters, but houses in which cases occurred generally defective in lighting, ventilation, or overcrowding, 16,971–86.
Plague chiefly in low, damp, dirty, and ill-ventilated habitations, 11,848.
Plague very common in houses with no light and air, 2784.
Poona: Bad houses most exposed to attack, 21,505.
Poona: Sadashiv Pet: Particulars of houses affected, III. 157.
Poona: Well ventilated spacious houses escaped plague, 21,547.
Poona: The great mortality in certain parts of the city ascribed to the insanitary conditions of the houses, 12,880.
Rats die in well ventilated sanitary houses without plague following, 1147, 21,538.
Surat: Dirty houses attacked, 2048.
The poorest who live in damp, filthy localities are most susceptible to, 25,256.
Virulence and extension of disease dependent upon dirt, over-crowding and want of ventilation, 11,281.
Virulence of epidemic varies with badness of housing, 8298.
Worst cases of plague in ill-ventilated and overcrowded houses, 11,228.

See Air and light.
„ Overcrowding.
„ Sanitary conditions.

HUBLI:

Introduction and course of plague:

Attempt to confine plague to the chawls by a cordon failed, and first cases in town were those of persons who passed through the cordon from the chawls, 1583, 2407, 2436–8, 20,151.
Epidemic slight in beginning of 1898, and did not become severe till May, 1582, 1587, 20,168.
First epidemic in railway chawls, first case coming to notice on 15th October 1897, 1576, 2396–9, 19,971.
Infection said to have been first imported by persons who came with the disease from Sholapur, 2398.
Infection said to have been first imported by railway employés who had been to Poona and contracted the disease there, 20,141–2.
Plague attacks and death-rates, I. 412–6.
Plague may easily have been reimported in May 1898 by sick persons, or the infection already imported into the town may never have died out, 20,170.

HUBLI—*cont.*

Population at beginning of epidemic 57,000, 1570.
Statistics of attacks, deaths, and inoculation, 1598, 1615, 25,151.
Suggestion that the increase of plague in May 1898, after apparent cessation for a short period, was due to the reimportation of the infection in merchandise, 2413, 2441.
Woman who returned from Bombay in February 1897 developed plague, but disease did not spread, 2396.

Inoculation with Haffkine's prophylactic:

Both inoculated and uninoculated left the town, 3085.
Fifty-eight thousand and eighteen operations in 15 weeks I. 407.
History of inoculation at, 70.
Inoculations: Began on 11th May 1898, 1936.
Inoculations: Discrepancies in statistics, 3056–65.
Mortality from plague and other causes in inoculated and uninoculated, May to November 1897, 1819–24.
Report on inoculations at Hubli, I. 398–409
Statistics relating to inoculations, I. 65.
Statistics (corrected) relating to inoculation, 25,151.
Whole population inoculated in Hubli, except sick and aged, 1689.

HYDROCHLORIC ACID:

Result of experiments, II. 8.

See Perchloride of mercury.

HYDROGEN:

Growth of Bacillus of Plague in:

Experiments on the growth of the plague microbe in air with admixture of hydrogen, 18,893.
Plague bacillus survives 5 days' desiccation in hydrogen, II. 8.

Isolation of Bacillus of Plague in:

Failure of attempt to isolate the plague bacillus from earth in an atmosphere of hydrogen, 26,387.

IDENTIFICATION OF BACILLUS OF PLAGUE.

See Isolation of bacillus of plague.

IDENTIFICATION OF INOCULATED PERSONS.

See Inoculation with Haffkine's plague prophylactic.

IMMUNITY FROM PLAGUE:

Classes of Persons alleged to be immune from Plague:

Alcohol consumers, III. 43.
Bhang consumers, III. 43.
Ganja smokers, III. 43.
Lepers, 917.
Opium eaters and smokers, III. 43.
Prostitutes, 917.
Syphilitic persons, 8693–4, 22,487, III. 43.

General Remarks regarding Immunity from Plague:

Immunity not racial, 19,448.
No such thing as complete immunity, 27,375.
Observation on immunity in different classes of people and castes during the present epidemic, 22,264–7.

See Europeans.
„ Inoculation of plague virus.

IMPORTATION OF CASES: *Instances in which Imported Cases were Numerous:*

A large number of importations or contacts are necessary in order to establish plague in a place, 16,000.
Ahmedabad: 77 plague cases (the majority bubonic) discovered at Ahmedabad Station among passengers from Bombay between October 5th, 1896, and February 16th, 1897, 13,886, 13,906, 13,908.

IMPORTATION OF CASES—*cont.*

Ahmednagar: 1896, 26 imported cases and no spread of infection, 24,216, 24,225.
Bhuj: Cases imported into, but no epidemic, 13,407.
Cutch Mandvi: Local cases began in March 1897; up to end of February 1897, 47 imported cases detected, 13,360–2, 13,519, 13,760.
Cutch Mandvi: 26 cases imported in January to April 1898 in period before second outbreak and when indigenous cases were very few, 13,411.
Hyderabad (Sind): 34 or 35 imported cases before infection became local, 18,087.
Mundra: 26 imported cases, with 17 indigenous cases, up to 6th June 1897; the main outbreak commenced later in August, 13,401.
Nasik: 26 imported cases, mostly bubonic, before outbreak commenced, 14,705–11.
Nasik: 35 cases of plague imported before disease became indigenous, 23,319.
Poona: 63 cases imported by railway before indigenous cases occurred in first outbreak, 12,856–9–62.
Poona: 30 imported and no indigenous cases between second and third outbreaks, 21,687–8.
Rohri: 22 cases imported from Sukkar between February 22nd and April 17th, 1897, 12,021–5.
Surat: Series of imported cases, 33 occurring before plague became indigenous, 15,556, 15,561–3.
Surat: Between March 1898 and February 1899, 16 imported, and no indigenous, cases, 15,750.
Wai: Notwithstanding influx of people from infected quarters, Wai remained entirely free from plague, 17,605.

INCUBATION PERIOD OF PLAGUE:

Arranged under the following subheads:

Incubation Period in Cases of Plague contracted from direct Inoculation.
Incubation Period in Cases that may be cited in connexion with the above.
Incubation Period in First Cases on Introduction of Plague.
Incubation period in Plague Cases contracted by direct infection from Rats.
Incubation Period in Plague Cases contracted by Visits to Infected Places and Houses or contact with the Sick.
Opinions regarding the Incubation Period.
Plague Cases of exceptionally long alleged Incubation Periods.
Plague Cases in Segregation Camps and Hospitals showing the Number of Days after Admission on which they developed.

Incubation Period in Cases of Plague contracted from direct Inoculation.

A compounder at Hubli was bitten on the thumb by a pneumonic patient and fell ill 3½ or 4 days after, 4567.
A Dome died 48 hours after assisting at a post mortem, 6921.
A Dome who assisted Major Gifford in the post mortem last-mentioned, died of plague; his relatives said he was taken ill 3 days after the post mortem, 6503–6.
A medical student who assisted at a post mortem, and made smear preparations, got plague 14 days after. Between the post mortem and his illness he worked regularly in the laboratory with plague material, the usual laboratory precautions against infection being taken, 6888, 6927–32.
A man who assisted at a plague post mortem on 3rd June is said to have injured his hand. Major Green was informed on 8th June that he was ill of plague, and had had fever for 2 days, 6894 (7220, D 28).
A student in the Jamsetjee Hospital was assisting in the post mortem of a case of plague, and he pricked himself in the left thumb, a very slight prick, which he did not notice at the time. About 3 days afterwards, he got a bubo in the corresponding left axilla and died of plague, 1411.
At the post mortem of first discovered case of plague in Calcutta, on 17th April 1898, at 8 a.m., Badri Dome scratched his hand. At noon on 19th he was found to have fever, and plague declared itself, 6462, 6493.

INCUBATION PERIOD OF PLAGUE—*cont.*

Dome, who assisted at post mortem, and did so on 27th and 29th April, and 1st May, on last date got a scratch; fever was noticed in the evening of the 2nd, and the man died of plague on the 3rd, 6923–5, 6988–95.
Dr. Sticker, of the German Plague Commission, had several times cut or otherwise wounded his left hand without any evil consequences at post mortems made during the second week in March 1898. On March 26, he performed three post mortems, and one at 3 p.m. on March 29th, without wounding himself. At 6 p.m. on the 29th, on drying his hand after a bath, he noticed over the metacarpo pharyngeal articulation of the right thumb a small, slightly painful, vesicle. This received a blow the same evening, and the arm at once became painful and plague developed, the bacilli of plague being recovered afterwards from the vesicle, 4562–9.
During post mortem on pneumonic corpse, a Hospital Assistant pricked a finger of his left hand at 3 p.m. on March 14. On the evening of the 16th he felt ill, and plague set in, 7218.
On October 7th 1897, an imported case of plague died at Poona; on Thursday Major Gifford made a post mortem; on Sunday Major Gifford felt unwell, on Monday he he had to go bed, and went through an attack of plague, 6496, 6502.
On 17th January 1898, Hospital Assistant got scratch on back of right hand at post mortem of pneumonic patient; plague manifested itself in 36 hours, fever setting in on afternoon of January 19th, 9393, 9566.
On 21st December 1897, about 5 p.m., Captain Leumann scratched himself at a post mortem. On 24th December he had a feeling of malaise all day; in the evening suffered from a sort of mental aberration; got fever, and an enlargement of glands in the armpit, on the same side as the scratch, and then went through a slight attack of plague, 4542–55.
Sputum was accidentally introduced into the eye of a nurse in Parel Hospital on the 15th February. On 18th feverishness set in, and next day the plague symptoms were marked, 7213–5.

Incubation Period in Cases that may be cited in connexion with the above:

A nurse at Poona who was attending on pneumonic patient died of pneumonic plague, as proved by bacterial examination of her sputum. She had not been long in attendance on the patient, perhaps 2 or 3 days, 7576.
A patient came to hospital and was there two days till he died. A friend came from an uninfected place to nurse him while in hospital. She fell ill of plague three days after the death. Other similar cases noted, 4316–9, 4323–5.
A phthisis patient in the police ward of the Civil Hospital, Karachi, who had been in since 12th January, got a sudden rise of temperature on 6th February and developed plague. A case admitted on 1st February probably infected him, that case having developed buboes and died on the 4th, 12,387.
Man got plague and was in hospital from 31st March to 9th April, when he died with secondary pneumonia. His brother went to hospital to nurse him, and developed plague on the 13th, 13,003–15.
Policeman A. died of plague of the pneumonic form in the lines on 18th April. On 26th April Policeman B. got a wound on his right foot at noon, was admitted to hospital that night, and developed plague next morning, 12,380.

Incubation Period in First Cases on Introduction of Plague:

A man went to Guntakal when it was infected. The day after his return home his daughter sickened of plague; she died the following day. The man was well until her death, but he died of plague shortly after. Infection

could have been communicated to the girl only through her father, 4481.
In Kelwa 5 days after the arrival of people from Bombay, who stayed 3 days, plague broke out among men, rats having died before, 23,207.
In Kersova a case was imported on 30th, proving fatal on 31st January. The schoolmaster who lived in the Talati's house visited the patient, and on 2nd February the Talati's nephew sickened, 23,207.
People from Bombay stopped 3 days in Ahmedabad; 3 days after they left plague occurred among the people with whom they had stayed, 15,202.
The first case in Shriguppi was a member of the family of a man who went to an infected place. This case was attacked about 4—not more—days after the man's return. The man himself suffered later, 2107–14.
The first imported case at Bangalore Civil and Military Station was taken ill on his return on 12th August after 3 or 4 days in Hubli, 2538.
Two servants belonging to Banniahs in Sharafi and Reri went to the Joria Bazar on 16th May and returned on the 19th; one got plague on the 21st in Reri and the other on the 23rd in Sharafi; 4 of their masters, probably infected by them, got plague on 24th May, 12,446.

Incubation Period in Plague Cases contracted by Direct Infection from Rats:

A listless rat was sound on the 5th March, and 8 days after a servant boy, who is said to have killed and burnt a rat, was attacked with plague, 17,996.
An imported case, Khandwa, developed plague 25th October, and died 29th. Dead rats found on 30th and 31st October. Boy, who was playing outside the verandah of the room where the man died, and must have been infected from the first case by the rats, attacked 2nd November, 5958.
A woman got a dead rat on her hand in taking out rice, and next day she got plague, 19,023.
Fitter in Karachi who played with a rat got plague three days after, 11,418.
Four cases in Customs' Lines after finding of dead rats and pending removal to huts, and no cases after, 11,976.
In Areh dead rats were found on 1st and 2nd October in 2 houses; on 3rd October plague broke out in both houses, and those adjoining, 22,223.
In Bhiwandi plague broke out in a house 7 days after dead rats were found there, 22,223.
In Jegapur 2 or 3 days after a man returned from Dharwar rats died, and 3 days after his daughter was attacked, 23,207.
New Kurla: Dead rats found 4th April; plague occurred 8th, 23,207.
On the fourth day after dead rats were found in the Karad Post Office the postmaster's daughter was attacked, 14,363.
On 19th November rats were found in a house; one old lady threw them away; other rats were found on the 24th; on the 29th the old lady got plague, 1180.
Pali: Dead rats found 6th or 7th January; plague occurred 13th, 23,210.
Santa Cruz: Dead rats found 12th February; plague occurred 15th, 23,207.

Incubation Period in Plague Cases contracted by Visits to Infected Places and Houses or contact with the Sick:

A compounder attacked with plague on May 4th was probably infected on the previous evening by a visit to a non-disinfected house where he went to get an article, 10,588–91.
A disinfected family that re-occupied a disinfected house had four cases of plague (including one death) within five days of re-occupation, 11,271.

After evacuation had stopped the plague in Pademal, people were, on 29th June, allowed to re-visit their houses for disinfection, and on 4th July cases began again, 22,737.
After the people of Trimbak in camp were perfectly free, 2 cases suddenly occurred; the patients had gone in the previous evening to an infected temple to get grain, 13,814.
Andumbar: Three cases of plague occurred the same day or the next day among people who had re-visited their houses for disinfection, 22,732.
An infected room was left vacant till 15th April. A man then went to live in it, and got plague on 18th, and later on, on 14th May, another man, who had used the place for cooking for 2 or 3 days only, got plague there, 11,266.
A man who assisted in carrying a plague corpse got plague 4 days after, 19,038.
A prostitute who about 23rd April re-occupied a disinfected house getting plague 4 days later, 11,276.
Chak Kalal: Series of cases on occupying infected houses, 10,109–10, 10,189, 10,603.
In Bada, after 17 days freedom, people were allowed in for 4 days on occurrence of rain; immediately they came out again there were 4 cases. Same happened in Salaya, 13,456.
In Hinganghat from 26th November to 1st December there was little plague, only one attack. On 2nd December plague started again with 6 cases. On the 28th people were prematurely allowed to re-visit their shops; they did so on 29th November, and this led to the cases of 2nd December, 6006–11, 6024.
In Joo people left their houses for some time on dead rats being found, but returned prematurely: three days after their return plague appeared among them, 23,216.
In 2 cases men from Kankhal who went to Jawalapur to see after the disinfection of their houses got plague in 3 or 4 days after, 9226.
Mahlgahla: Cases after occupying infected houses, 10,348.
On 20th April a disinfected and vacated house was re-occupied; plague occurred there again on 24th, 11,276.
Poona: European editor of paper went out with a search party the first day such parties went out. He lived in an uninfected part, and was not otherwise in contact with plague. The same day he developed the disease, 12,883–8.
Succession of cases connected with the Backergunge epidemic, 6835–9, 7350–94, 7409–13.

Opinions regarding the Incubation Period:

About a week, 3375–6.
About 8 days, 13,016.
Appears to be from 2 to 10 days, 45.
Eight to 10 days, 1899.
Five to 10 days, 4457.
From 3 to 5 days. Longer periods mostly mild cases, 25,485.
Incubation period from 2 to 4 days, 8640.
Majority of cases in camp developed in 48 hours after admission, 17,368.
May extend to 15 days, 3139.
Most difficult to ascertain period of incubation when the infection is through clothing, 8640, 13,023.
Ordinarily from 24 hours to a week, 3375–6.
Over 10 days, 1903.
Period of incubation from less than one day to 10 days, 10,407–12.
Period certainly up to 10 days, 10,196.
Period in some cases under 2 days, 1198.
Some cases have incubation period over 10 days, 12,505.
Ten days a liberal allowance, probably shorter, 1619, 1796, 2833.
Usual period 4 or 5, extending to 10 days, 226.
Varies from 1 to 8 days, I. 351.
Varies from 36 hours to 10 days, I. 399.

INCUBATION PERIOD OF PLAGUE—*cont.*

Plague Cases of exceptionally long alleged Incubation Periods:

Cases in which incubation period was beyond 10 days, II. 184.
Dharwar: Contacts got plague up to 18 days, 1902.
Details of cases in plague hospital, Baroda, in which the period of incubation appeared to be more than 10 days, II. 285–6.
On 3.12.96, a Parsee child arrived in Poona from the Fort, Bombay, where there was plague. She got plague 14 days after, on 17th December. There were suspicious cases in Poona City, but the child had not access to the city, 12,889–92; 21,658–63.
Statement of a number of cases that occurred more than 10 days after removal to segregation, as proof of a period of more than 10 days but these cases may have been due to a surreptitious visit to an infected house, 22,330, 22,414–22, 22,456–80.
Statement of 7 cases said to have a period of over 10 days; the histories are not detailed enough to show exact source of infection and exact length of period, 15,293.
Syce who came from Bombay to Baroda 5 weeks before was attacked by plague, 15,187.
Ten days after wearing a pair of shoes that gave her a sore on her heel the day she wore them, a Parsee lady developed plague. She lived in a non-infected quarter, 20,658.
Woman develops plague on 10th day at Bandra, 8240.

Plague Cases in Segregation Camps and Hospitals showing the Number of Days after Admission on which they developed:

Anand, 14,182, 1291.
Anand detention camp, one case on the 11th day, 14,138.
Ankleshwar, 14,215.
Bangalore Civil and Military Station, 25,030.
Bhusawal, 1,291.
Bombay (Wari Bundar Camp), 301, 17,367, 20,442.
Dharwar, 1,926.
Gadag, 23,693.
In Kalankot and Gharibabad, evacuation stopped plague 8 days and 2 days after evacuation, 11,145–6, 11,163–6.
Poona: 1st and 2nd epidemics, 21,835.
Poona: 3rd epidemic (to March), 25,827.
Porbandar, 13,722,
Porbandar: Dates of developing plague after arrival in observation camps, ordinary period not more than 9 days, 13,662, 13,744–7.
When two members of a family were attacked the other members were segregated; one of the persons segregated developed plague 9 days after segregation, 4320.

See Inoculation with Haffkine's plague prophylactic: *Effect on incubating plague.*

INFECTED PLACES; *Miscellaneous particulars regarding:*

Ahmedabad: Bombay, plague introduced from into, 13,855.
Ahmedabad: First plague cases among the mill hands occupying a dehla outside the Sarangpur gate, 13,918.
Ahmedabad: Table showing number of plague cases, imported and indigenous, from October 1896 to April 1898, II. 228.
Ahmednagar Cantonment: First case in September 1897, 24,136.
Ahmednagar City: First cases in, October 1897, evacuated November 1897, 2, 24,237.
Ahmednagar City: Four hundred and seven cases and 315 deaths from October 1897 to March 1898, 24,238–9.
Ahmednagar City: Plague travelled in a line from house to house and ward to ward, 24,234.
Alibag: Latest outbreak among Brahmans, former among the Kolis, 17,621.
Ankleshwar; Population, 10,700: First cases among the Ganchis in April 1898, 14,205–6.
Ankleshwar: Table showing monthly mortality from April to November for the years 1896, 1897, and 1898, II. 247*a*.

INFECTED PLACES—*cont.*

Ankleshwar: Table showing weekly attacks and deaths from plague in 1898, 14,214.
Ankleshwar Taluka: Table of weekly attacks and deaths in the villages during the year 1898, II. 239.
Backergunge: Epidemic at, 6836–43, 7331–475.
Backergunge: Plague bacillus not found in sputum of pneumonic patient at, as examination could not be made in time, 7471–4.
Bantwa: Population 8,500; Epidemics August and September 1898, deaths 602 in 944 cases, 17,549–55.
Baroda Cantonments: Table of deaths from causes other than plague, from August to December, 1898, II. 289.
Baroda City: First outbreak began April 1897, second began October 1897 and ended April 1898, 14,584, 14,596, 14,628.
Baroda City: Population 112,500, 14,582.
Baroda City: Table of mortality from plague and other causes, January 1897 to January 1899, 14,983.
Baroda City: Influx of people to Baroda from infected places, especially Surat, 14,599.
Baroda City: Table of gross mortality three months before outbreak, II. 274.
Baroda City: Table of weekly gross mortality from plague and all other causes, II. 274.
Baroda City: Table showing progress of plague from January 2nd to April 9th, 1898, II. 287.
Baroda City: Table showing weekly number of plague cases from October 1897 to January 1899, II. 253.
Baroda City: Table showing weekly returns of mortality from October 1897 to January 1899, II. 252.
Baroda State: Dhamdachha: first epidemic among the Kolis and Pattidars; the second epidemic began among the Kolis, 15,120.
Baroda State: Ratio of number of attacks to population in the several divisions, II. 283.
Baroda State: Table showing ratio per 1,000 inhabitants of plague deaths in different villages, II. 282.
Baroda State villages: Statistics regarding the plague outbreaks and inoculations, 14,793–4, 14,834–981, II. 496, 502, II. 503–21.
Belgaum: Account of the introduction of plague in Belgaum, 23,028, 23,031.
Belgaum: First epidemic October 1897 to June 1898, 23,124.
Belgaum: Plague began among the Muhammadan Kolis, 1715.
Belgaum: Population about 28,000; 23,122.
Belgaum: Second epidemic began July 1898, 23,125.
Belgaum: Sweepers first infected in Belgaum, 2086.
Belgaum: Table showing number of plague cases from October 1897 to end of January 1899, III. 210.
Bhiwandi: Plague epidemic from May to September 1898, 22,111–3.
Bhiwandi: Population 15,000, 22,108.
Bhiwandi: Table showing attacks and deaths from plague, 14,482.
Bombay Presidency: Deaths from plague, 61,915 from May 27 to November 25, 1898, 3.
Bombay Presidency: Deaths from plague to May 1897, 28,737; to May 1898, 61,219; and in 1898–9, to 3rd March, 94,000, 26,536–7.
Bombay Presidency: One-half of the plague mortality in Bombay Presidency occurred in the districts of Dharwar and Belgaum, 26,537.
Bombay Presidency: 94,000 deaths from plague in the Presidency during the first three epidemics, 26,536.
Broach: Infected in September 1898, arrangements made, 15,484.
Broach: Lower classes and Banniahs suffered most, 15,470.
Bulsar: First epidemic in early part (February) of 1897, 19,940.
Bulsar: Plague probably did not spread from Dhebras to Tais in Bulsar, 16,179.
Bulsar: Second epidemic began in April 1898, 16,159.
Cutch Mandvi: Account of the outbreak at Rawapur in 1897, 13,364.

INFECTED PLACES—*cont.*

Cutch Mandvi: First cases, probably about February 1897; most virulent, 455.
Cutch Mandvi: First epidemic, 4,298 cases, with 4,224 deaths, 13,384–5.
Cutch Mandvi: First imported cases in October 1896, 13,358.
Cutch Mandvi: History of cases among the Megwals, 13,408–10.
Cutch Mandvi: History of former epidemics, 13,356.
Cutch Mandvi: Khatris suffered most during first outbreak at Mandvi, 13,417.
Cutch Mandvi: No cases among the Waghris, who live in grass huts outside Mandvi, 13,480.
Cutch Mandvi: Not visited by plague since 1817 until now, 13,351.
Cutch-Mandvi: Particulars of deaths from causes other than plague from February 20th to March 9th, 1898, II. 218–9.
Cutch Mandvi: Report of an outbreak of disease in Cutch Mandvi, II. 405–8.
Cutch Mandvi: Salaya: Two hundred and thirty-three cases and 176 deaths during the second epidemic, 13,433.
Cutch Mandvi: Second epidemic from March 1898 to January 1899, 992 cases and 748 deaths, 13,412.
Cutch Mandvi: Second epidemic severe from March to end of May 1898, with 288 cases and 202 deaths, 13,411.
Cutch Mandvi: Severe epidemic of fever in 1878, 13,357.
Cutch Mandvi: The town being a mile square contained 40,000 people before the outbreak, 540.
Dharwar district: Attacks and deaths, I. 72.
Dharwar district: Plague introduced into the villages from Hubli, 23,499.
Dharwar district: Statement of attacks and deaths, I. 72.
Dharwar district: Statement of the course of the epidemic in Byahatti, 2192.
Dharwar district: Statistics of very severe plague in certain villages in which measures could not be properly carried out, 1601, 1719, I. 92–3, 23,518.
Dharwar Jail: Plague in, 2227–303.
Dharwar Town: Measures applied to plague infected houses, 1610, 1943–5, 2328–37, 23,747.
Dharwar Town: Plague began among the Muhammadan Kolis, 1715.
Dharwar Town: Population 32,000 at census, 38,325 in August 1898, 1571, I. 67.
Dharwar Town: Statistics of attacks, deaths, and inoculations from middle October 1898 to middle December 1898, 1608, 25.151.
Guntakal: Course of infection around, 5039–47.
Hinganghat: Daily mortality, 6096.
Hinganghat: In spite of precautions taken, plague imported, and escaped detection till November 19, 1898, when it had been some time in the town, 5948–59, 5977, 5980, 6001, 6083–8, 6,200, 6289, 6395–9.
Hinganghat: Plague mortality, 6197.
Hinganghat: Suggestion that plague was introduced by two mill hands from Bombay who came to the town, but did not themselves develop plague, 6200, 6240–7, 6293.
Hinganghat: Table of death-rate, 6,200.
Hyderabad (Sind): Population 65,000; slight increase by arrivals from Karachi before plague broke out; no great decrease after plague broke out, 18,114–7.
Hyderabad State: Plague imported from Sholapur, and first cases in January 1898; measures adopted, 5,153.
Hyderabad State: Statistics of plague in villages of, I. 194–6.
Igatpuri: Statement of course of plague for 1897, III. 219.
Igatpuri: Table of plague cases and deaths, III. 90.
Ilkal: Table of plague cases and deaths, III. 90.
Kaira district: No direct evidence to show how plague was introduced in the, 14,025.
Khandraoni: Gwalior State: List of persons attacked with plague in 1897, II. 71.
Kotri: First case in second outbreak a Hindustani, plague then spread to Banniahs and Muhammadans, 12,597.

INFECTED PLACES—*cont.*

Kotri: First imported case, January 24, 1897; last March 26, 12,532.
Kotri: Table of deaths from all causes during September and October 1897, II. 452–4.
Kotri: Table of particulars regarding the first 20 cases in the second outbreak, II. 182–3.
Kotri: Table showing total mortality during January, February, and March, 1897, and average mortality during the same month for five years, 12,556.
Kotri: Table showing weekly death-rate from April, 1897, to end of January, 1898, II. 182.
Madras City: Though no plague about end of 1898, death-rate abnormally high, 3904.
Madras Presidency: Infection first appeared about August 1898 in the Anantapur district, 3882–93, 4101–19.
Mysore City: First infected on 2nd October 1898; measures adopted, 3202–481.
Mysore City: Statistics of incidence of plague, III. 274–5.
Mysore State: Dates of first spread of plague in villages, 3302.
Nasik: A great centre of pilgrimage, 13,751.
Nasik: Epidemic ceased end of March 1898; 450 cases in all, 16,837, 16,946.
Nasik: First case a Muhammadan dealer in rice, 13,756.
Nasik: First cases, October 1897, 2, 16,920, 16,966.
Nasik: First indigenous case among the permanent population, 13,753.
Nasik: Permanent population of Nasik between 25,000 and 26,000, 13,752.
Nasik: Plague introduced from Bombay, 18,068.
Nasik: Plague supposed to be introduced from Ghoti, which had been infected from Bombay, 13,756.
Nasik: Table showing number of plague cases from November 12th, 1897, to April 8th, 1898, II. 2565.
Nasik: Total mortality from February 3rd, 1897, to April 8th, 1898, 14,732.
Palanpur: First outbreak February to May 1897, 141 cases and 90 deaths, 13,051–3, 13,859.
Palanpur: Second epidemic August 1897 to January 1898, 13,057, 13,060, 13,095.
Palanpur: Second epidemic, 674 cases and 413 deaths, 13,101.
Palanpur State: Dates and particulars of outbreaks in all places infected in 1897–8, 13,159.
Palanpur State: List of villages, population, date of first case, evacuation, &c., II. 199, 200.
Panjab: Jullundur district: Table of mortality, II. 96.
Panjab: Khatkar Kalan first village attacked; plague detected October 1897, 9917–30.
Panjab: Measures taken on appearance of plague, 9934.
Panjab: Rahon: No data to prove how Rahon was infected, 10,534, 10,553.
Panjab: Table of statistics in reference to the plague at Sotran, Lidhar Kalan, Khanpur, Bika, Punian, Gosal, and Kariam, II. 107–10.
Panjab: Table of summary information concerning the plague-infected villages, II. 404–7.
Panjab: Table showing mortality in villages according to their population, II. 94–95.
Poona Cantonment: First infected June 1897, 21,193.
Poona Cantonment: Infection spread from Kirki and became epidemic in August 1897, 21,206–8, 21,247–8.
Poona Cantonment: Last case December 1897, 21,221.
Poona Cantonment: Measures adopted and organisation, 21,259.
Poona Cantonment: Two hundred and ninety-eight deaths in 1897 epidemic, 21,316.
Poona City: During first outbreak only eastern part affected, and during the second only the western, 21,533.
Poona City: First case December 1896; second epidemic, August 1897, 2.
Poona City: First epidemic December 1896 to May 1897, 21,674, 21,679.
Poona City: Second epidemic commenced August 1887, ended February 1898, with 4644 cases and 3633 deaths, 21,681–5.
Poona City: Statement of attacks and deaths from plague recorded from February 14th to March 17th, 1899, III. 318.

INFECTED PLACES—*cont.*

Poona City: Statement of figures of normal and actual mortality from February 14th to March 17th, during the years 1897 to 1898, III. 318.
Poona District: Poona collectorate death-rate rose suddenly in one month, just before outbreak in Bombay, by 1,000, 905.
Porbandar: First cases among the Kharwas 13,665.
Porbandar: Plague spread from the Kharwa quarter to that of the Bhois and Borahs, 13,680.
Porbandar: Plague spread from the Kharwas to the Muhammadans, the Turias, the Julahas, the Sepoys, and Memons, 13,705.
Porbandar: Statistics of plague for 1898, II. 483–5.
Rohri: Course of epidemic impossible to trace at, 12,096.
Rohri; One hundred and fifty-one cases and 92 deaths, 12,043–4.
Rohri: Outbreak of plague in the suburbs, 12,078.
Rohri: Plague appeared in March 1897, 12,024.
Satara: District plague returns 1897–99, III. 181 191.
Satara: History of epidemic, 22,093.
Sholapur: Epidemic started among the servants of the Europeans, 23,893.
Sholapur: Infected in October 1897, 2, 20,225, 23,888.
Sholapur: List of weekly number of attacks and deaths, II. 242.
Sirohi State: Table of cases, 9886, II. 75.
Sukkur: First case in February 1897, 3723.
Surat: First epidemic, 49 imported and 65 indigenous cases, 15,626.
Surat: First epidemic lasted from February to May 1897, 24,378.
Surat: First imported cases, December 8th, 1896, 15,556.
Surat: Plague begins February 1897. Second epidemic in August, 2, 15,856.
Surat: Plague imported from Bombay, 16,053.
Surat: Sudden outbreak of cholera and plague in jail, 15,789.
Surat: Table of number of cases during the first epidemic, II. 295.
Surat: Table showing total mortality between the two epidemics, II. 302.
Surat: Table of weekly mortality from December 1st, 1896, to May 31st, 1898, II. 298.
Surat: Total of cases and deaths during first and second epidemics, 15,728.
Table showing plague cases and deaths at several large places, II. 258*b*.
Umreth: First case in the Kaira district occurred at, 14,014, 14,019.
Umreth: First detected cases in the Gola quarter, 14,027.
Umreth: Plague officially declared on September 26th, 1898, 14,020.
Umreth: Table of weekly attacks and deaths, II. 232.
Wardha: First cases on 5th December 1898, 6212.
Wardha: Statistical table of mortality and course of plague, 6197, I. 224.

INFECTION BY LOCALITY.

Both pneumonic and bubonic plague are infectious in the houses in which the disease exists, 10,227–9.
Danger lessens with distance from centre of infection, 26,537.
Disease is intensely local in floors, 23,245–8, 23,285.
Disease spreads rather to neighbouring houses than by human agency, 13,698.
Houses do not seem to be themselves infective, 16,004.
Infection appeared to be in the ground and local at Hubli, 1645.

INFECTION BY LOCALITY—*cont.*

Infection not from person, but from locality, 1947.
Localisation of epidemic well marked in several areas, 26,537.
Locality seems to be infected, 9275.
Person to person infection rare; locality the cause of infection, 18,146.
Plague a disease of locality, 1650, 18,108.
Plague poison mostly located in the houses, 17,727.
Plague generally extends by continuity of dwellings, 22,067.
Residence in an affected area communicates the contagion, 21,537.

See Incubation Period: *Incubation period in cases contracted by visits to infected places or houses or contact with the sick.*
,, Floors.
,, Recurrence of plague in infected towns and villages.
,, Recurrence of plague in the same house or locality.

INFECTION, MODES OF:

By Lesion of the Skin:

Bacillus enters body through open sores, 20,386.
Bacillus introduced into the body by fissures in the skin, 16,068.
Bacillus produces plague through infection of the distal lymphatics, 20,385.
In bubonic cases the virus enters the system through lesions in lymphatic connexion with the particular set of glands affected, 17,367.
Infection of bubonic plague through abrasions, 12,359, 17,775, 18,174.
Infection most frequent through the skin, 7076, 20,586.
Infection by skin far commoner than supposed, I. 350.
Infection probably by lesions of the skin in some instances, 1391, 7076.
Infection possible by scratch or cut, 338.
Infection through wounds and cracks in the skin, 15,275, 16,007, 16,068, 18,048, 18,051, 18,113, III. 42, 18,177, 18,506, 19,965, 20,386.
Plague bacillus found in small lesion near bubo in four cases, I. 374, 1393.
Report of cases in which the virus had been introduced through abrasions of the skin, 12,875, 6908–10, 7302.
Seventy-five per cent. of plague cases contracted through local lesions, 11,579.
Skin of the Feet: Disease contracted through abrasions of the toes, 1003.
Skin of the Feet: Frequent cracks on native feet make infection through the skin probable, 534.
Skin of the Feet: Point of infection generally in lower extremity, 2374.
Skin of the Feet: Sweepers infected through the skin of the feet, I. 442.
Skin of the Feet: Through the abrasions in skin of the feet, I. 351,1781.

See Incubation period: *Incubation period in cases of plague contracted from direct inoculation.*
,, Lesions.

By Means other than Lesions of Skin:

Cutaneous inoculation not usual mode of dissemination, 221–37, 337, 347.
Difficult to believe that all bubonic cases should be due to abrasions of the skin, 9389.
Fissures in skin not so constant as to warrant any decided inference to their being the way of infection, 18,108.
Infection through the skin improbable, 232.
Introduction of plague through the skin a rare occurrence, 9383.
Many other lesions by which plague might enter except the skin, 1505.
Multiple buboes evidence against cutaneous inoculation, 347.
No proof that skin is chief method of infection, 2728–9.

INFECTION, MODES OF—*cont.*

No lesions found in the skin of human beings or monkeys to account for the inoculation of disease, 9389.
Point of entrance in skin cannot be accurately indicated, 7211.
Very few cases confirmatory of inoculation through cuts and wounds, 22,360.

Infection through:

Alimentary canal: Possibly by alimentary canal, 7076.
Alimentary canal: Produces abdominal form of plague, very rare, 20,388, 22,325.
Alimentary canal: Through alimentary canal possible, 7211.
Eye: Infection entered through the conjunctiva in one case, 7211, 7215.
Eye: Infection by microbes entering the body through the corners of the eyes and nostrils, III. 42.
Eye: Infection through the mucous membrane of the eye, 20,530.
Lungs: Infection chiefly through inhalation, 22,360.
Lungs: Means of infection not external, but pulmonary, 222, 230, 332–9.
Mouth: Cervical buboes in children probably the result of auto-inoculation through the mucous membrane of the mouth, 11,581.
Mouth: Infection by inhalation; probably through abrasions in the mouth, 7211.
Nose: Instance in which the nasal mucous membrane was the absorbing surface of infection, 20,394.
Sexual intercourse: Cases probably due to, 21,293, 22,264.
Stomach: No post-mortem evidence that infection contracted through stomach, I. 368, I. 375.
Tonsil: In buboes of the neck local lesion generally found on the surface of the tonsil, 11,580.
Tonsil: Of cervical glands through the mucous membrane of the tonsils, 21,761.

See Lungs.
,, Food.

Opinions of certain Witnesses regarding Modes of Infection:

Opinion of Mr. Davur, III. 42.
Opinion of Mr. Dantra, III. 271.
Opinion of Mr. Ghadiali, III. 271.
Opinion of Mr. Muhammad Nivaz Shah, II. 123.
Opinion of Mr. Nowrosji Desai, II. 291.

INFECTIOUSNESS OF PLAGUE:

Infectiousness of Plague from Personal Contact:

Among monkeys: did not spread among monkeys confined in open cages at Hardwar, 8739–45.
At Jamalpur plague mostly communicated from person to person in families, 9165.
Cases of infection by persons, 7243–60.
Cases of infection probably due to sexual intercourse with plague-infected persons, 21,293, 22,264.
Course of cases from person to person in Calcutta, 7509.
Course of cases from person to person in Surat, 16,045.
From person to person infection rare, 18,146, 18,789.
Infection not often communicated by touching plague patients, 22,554.
Infection in Kotri seemed to spread by contact of persons not from houses, 12,650.
Infection carried in Cutch chiefly by people, personal infection, 13,462.

INFECTIOUSNESS OF PLAGUE—*cont.*

Not infectious in the early stages, 1913.
Not a very infective disease, 26,714–7.
Not very infectious or contagious, 12,876.
People observed hugging and kissing plague patients without getting infected, 25,229–31.
Plague cases in camps and hospitals do not spread infection to any important extent, 10,374.
Spread of plague from a single case not noted in Bombay, 1269–71.
Very little infection from person to person, 17,722–3, 21,500, 21,538, 21,569.

Instances in which Infection has been severe in individual Families or Houses:

In Calcutta in a family of 15, 8 succumbed to plague, and in another case 11 persons died in one hut, II. 537.
In Hubli 9 persons out of a family of 13 died before the existence of plague among them became known to the authorities, 23,383.
In one family eight deaths occurred and in one compound 13 deaths out of 18 people, 3698.
In one house in Karachi no less than 21 people among 35 to 40 inmates caught the plague from one another, 12,333–4, 12,479–80.
Instance of a family of 13 members (Mr. Shelke's) in which infection spread and 9 uninoculated members all died, 1725.
One case in Kajurgi, Hyderabad State, introduced the infection and started an outbreak, 9 or 11 persons dying in one family, 5498–506.
Three persons out of five infected in a week in a small room, 18,321–3.
When ventilation openings closed, 20 cases at once occurred in a fairly sanitary chawl, which, though in the middle of plague, had before remained free, 22,382.

See Bubonic plague.
,, Infection by locality.
,, Pneumonic plague.
,, Septicæmic plague.

INFORMERS:

Cutch Mandvi: Poor people giving information of cases paid small reward, 13,436.
Hyderabad State: Reward of 10 rupees offered for information of an infected village. System worked well, 5439–42.
In large places only possible methods of discovering plague are paid informers, &c., 10,963.
Karachi: Rewards paid for the reporting of plague cases, 13,436.
Panjab: Good results of the system of rewards for information of newly infected villages, 9934–6.
Panjab: 50 rupees paid to informer who first gave notice of newly infected village. System worked well, 9934–6, 10,826.
Panjab: Banga, system of reward for notification of plague very successful in, 10,249.
Panjab: Banga, people under the belief that the first case was imported for the sake of the reward, 10,235.
Sukkur: Small rewards paid to informers, 18,385–6.
Surat: System of rewards to private persons, Sanitary Inspectors and police for information, 15,575–9.

INOCULATION OF PLAGUE VIRUS:

Confers special local immunity as well as general, 194.
Doses of virus necessary to produce the initial reaction must be increased in order to produce the same reaction subsequently, 27,376.
Immunity conferred by inoculation with plague cultures, living and dead, 27,355–7.

Inoculation of Plague Virus—*cont.*

Animals:

Immunity—Local and general immunity in animals produced by repeated inoculations of plague virus, 115–7.
Post-mortem appearances the same in animals partially protected by inoculation with plague virus and those dying without previous inoculation, 27,363.
Sterilized cultures of plague bacilli have not given the satisfactory results obtained with microbes of cholera and typhoid, 27,358.

Test for Presence of Plague by:

Method of testing for the presence of plague bacilli by inoculation of suspected substances into rats, an exceedingly sensitive method, 153.
Method used by Dr. Gibson, 619-20.
Not a good method, and gives doubtful results, 8522–4, 8588–9.

Test of Virulence of Plague by:

Inoculation into the peritoneum a surer and quicker method for testing the virulence of the microbe than subcutaneous injection, 17,413.

See Experiments on animals.
„ Inoculation with Haffkine's prophylactic.

INOCULATION WITH CURATIVE SERUM:

See Haffkine's curative serum.
„ Lustig's curative serum.
„ Yersin's curative serum.
„ Serum.

INOCULATION WITH HAFFKINE'S FLUID.

Arranged under the following subheads:

Adoption of Inoculation as a general Plague Measure.
After Effects of Inoculation with Haffkine's Fluid.
Age and Inoculation.
Animals, Experiments on.
Attitude of People towards Inoculation.
Bars to Inoculation with Haffkine's Fluid.
Caste, Religion, and Race; Inoculation with reference to.
Certificates of Inoculation.
Dosage.
Duration of Protection afforded by Inoculation.
Effects of Inoculation with Haffkine's Fluid—
Attacks; on Plague—
Clinical Symptons of Plague; on—
Incubating Plague; on—
Mortality: on Plague—
Other Diseases; on—
Spread of Plague; on—
Extensive Application of Inoculation: when resorted to and General Effects of.
History of Inoculation in particular places.
Identification of Bodies of Inoculated Persons.
Inducements to Inoculation with Haffkine's Fluid.
Investigation Sheets.
Method of performing Inoculations.
Period for which Protective Effect exerted.
Persons recovered from Plague; Inoculation of.
Reaction after Inoculation of Haffkine's Fluid.
Re-inoculation.
Registration of Inoculated Persons and Statistics regarding Inoculation.
Standardisation of Dose.
Strength of Haffkine's Fluid.

See also Haffkine's Plague Prophylactic, *arranged under the following subheads:*

Character and preparation of Haffkine's fluid.
Constituents of Haffkine's fluid.
Re-sterilisation of Haffkine's fluid.
Sterility of Haffkine's fluid.

Adoption of Inoculation as a general Plague Measure.

Cannot be trusted alone to stamp out plague, 22,411.
Prophylactic inoculations alone not sufficient to eradicate plague, 10,179.

Inoculation with Haffkine's Fluid—*cont.*

Preventive inoculation is limited in its applicability, 21,741.
People even if they admit its value will neglect it as they do small-pox vaccination, 7881.
Can never prepare a district against invasion of plague, 3872.
Impossible to rely on as chief measure, takes too long, 7882, 7988–90.
Inoculation not an indispensable measure in combating plague, 15,432.
Protective value proved, but it cannot replace sanitary measures, 274–5.
Must be secondary to sanitary measures, I. 407.
Inoculation combined with complete evacuation the ideal plague measures. 22,408.
Partial inoculation of villages unadvisable, 1958.
Not a plague policy in rural areas, 1858.
Recommended with caution, III. 43.
Segregation preferable to forcible inoculation, 7061.
Facilities should always be before the people, 923.
Inoculation stations, provision should be arranged for, 923.
Should be done by Government officials, 1963.
Essential for nurses and attendants, I. 383.
Value in preventing interruption of trade, 1956, 23,680.
Prevents panic and the scattering of the people, 3482, 18,430, 24,977–9.
Bose, Dr., formerly an opponent, converted by results, 7542.
Dinshah, Dr., thinks it had better be avoided, 24,935.
Lawrie, Col., thinks in no way to be recommended, 5161.

After Effects of Inoculation with Haffkine's Fluid:

Differ in different persons, 4748, 10,711, 10,799–802.

Abscesses:

Occur occasionally at point of, 4743, 4781, 11,705, 16,568.
Due to defect in antiseptic precautions and neglect, 1753, 4781, 10,714.
Ten in 2,500 cases, 1779; 2 abscesses, 1806; 8 in 27,000 cases, 1836; 12 in 75,000 cases, 3034.
None noticed, 664, 14,519, 16,317.

Alcoholism: One death at Bangalore after inoculation due to, 4636.

Apoplexy: Death 1½ months after due to, 14,819.

Boils: Attributed by population to, I. 477.

Buboes:

If resulting, appear near point of, 193, 1877, 2280–1.
Have occurred, not near point of, 16,327.

Cellulitis: Of whole arm form seat of inoculation to wrist, 4853.

Chorea and Tetanus: In a child follow, 4774.

Collapse: In a girl follows, 11,707.

Consumption: Attributed to, 201, I. 340.

Deaths:

Apparently due to inoculation fever, 4605, 4973, 2388.
Death not due to, 4754, 6370.
Death shortly after, 1820, 2763, 4605, 4763, 5074, 12,939, 14,092, 16,584, 19,106, 20,458.
Death shortly after, in inoculated mostly occur in first few days after inoculation, 3185
Plague bacillus found in 41 cases which died shortly after inoculation at Hubli, 3074.

Debility: General, caused by, 14,813–5.

Delirium follows: 2762, 6381–2, 16,592.

Depression: Great, caused by, 20,458.

Diarrhœa:

Followed, 4742.
Did not follow, 16,322.

Endocarditis: Death from, ascribed to, 20,458.

Erysipelas:

No case known to M. Haffkine, due to, 204.
Erysipelatous blush followed, 6302, 16,328.

Erythema: Followed, 5160.

Fainting: Followed, 4741.

INOCULATION WITH HAFFKINE'S FLUID—*cont.*

Fever:
Continued, followed, 23,699.
Course of in 826 cases, 10,863.
High fever, cases of, 5160, 6387–8, 23,705.
Apparently caused death of a boy after, 4605.
Two cases die of simple fever, 5123.

Gastric Irritability: caused by, 20,458.

Headache: Caused by, 14,519.

Hydro-nephrosis: Woman suffering from, died after, 4763.

Induration: Near point of, 6319.

Impotence: Two cases alleged to be due to, 14,818.

Leprosy: Alleged, 19,314.

Leucoderma: Alleged, 19,314.

Malaria: Followed, 6361.

Neuralgic Pains:
None due to, 14,818.
Follow, 14,813.

Pains in Joints and Muscles: Follow on, 23,707.

Permanent evil Results: None, 202, 705, 1481, 2759, 4635, 10,154, 10,645, 10,698, 14,518, 16,278, 16,322, 19,051.

Phthisis: Attributed to, 205.

Pregnant Women:
Take inoculation well, 4869, 23,732.
Woman died at Guntakal after, 5074.
No reason to refrain from inoculating with modified dose, I. 400.
Of two inoculated, one miscarried and one did not, 23,733.

Rashes: Caused, 19,306–19,313.

Rheumatism: Caused by, 14,821.

Severe Symptoms from:
Case of severe reaction, 4012.
In Europeans, 5124–6.
In the case of Colonel McConaghy and an Assistant Surgeon, 12,944–59.
Mr. Hogan's case, 6383.
Sirkar: Assistant Surgeon, description of personal experience, I. 227.
Surgeon-General Harvey's case, 5160.

Soreness: Continued for some days at point of, 6384, 10,648, 10,717.

Swelling of Arm: Followed, 4694, 4750, 6383–4, 10,715–6, 16,330, 16,578.

Syphilis: No case known to have resulted from, 204.

Tetanus and Chorea: In a child followed, 4774.

Tubercle: No case known to have resulted from, 204.

Urticaria: Followed, 1806, 10,717–8.

Vomiting:
Followed, 4742.
Caused death in 48 hours after, 2763.

AGE AND INOCULATION:
Children in arms not inoculated at Karachi, 11,737.
Children not suitable to inoculation, 13,442.
Effect of inoculation on children, I. 400.
Number of inoculated persons at Karachi classified according to age, II. 376.
Old and infirm persons excluded from inoculation, 1759, 15,442.
Old men up to 90 years of age and infants 2 months old inoculated at Alibag, 25,878.
Table showing the ages of inoculated people at Banga, II. 94.

ANIMALS, EXPERIMENTS ON:
Small dose does not protect rabbits, 5204.
Small doses of Haffkine's fluid have no protective effect on animals, 5161.
See Rabbits.

ATTITUDE OF PEOPLE TOWARDS INOCULATION:
Bangalore: People inoculated partly for protection, but chiefly to avoid segregation, 3170, 3184.
Baroda: Inoculations encouraged at Undhera and elsewhere; number of inoculated persons in the State, II. 517 (R).
Baroda Cantonment: Native soldiers refused inoculations, 15,434.

INOCULATION WITH HAFFKINE'S FLUID—*cont.*
Belgaum: Withdrawal of privileges put a stop to inoculation, 23,132.
Bombay: Better class came forward in, 48.
Bombay: 25,358 people inoculated in 1898 in, 1363, 1366.
Bombay: Disliked because of fever and inconvenience caused, and doubt as to value of, 921.
Bombay: Disliked because of fear of communication of disease by the syringe, 919.
Bombay: Opposition decreasing, 922.
Broach: Parsees and Muhammadans favour inoculation, 15,511.
Calcutta: Better class people, and the Muhammadan leaders, came forward, 6643, 6650.
Calcutta: People will not take to it before plague, 6651.
Calcutta: Grows in popularity, I. 476.
Calcutta: Only 2490 inoculations in three months, 6557, 6640, 6645–6.
Calcutta: People who undergo inoculation looked down on, opposition strong, 7532–3.
Calcutta: Plague officers attacked, supposed inoculator murdered, I. 469.
Calcutta: Wild popular rumours of its evil effects circulated, I. 475.
Dharwar district: Fees paid for inoculation, 170.
Dharwar: 18,000 people left in one week for fear of inoculation, 23,746.
Dharwar: People get inoculated to secure certificate and privileges, 1963.
Dharwar: Villagers anxious to get inoculated, 1961.
Gadag: Fees paid by the people for inoculation, 23,871.
Gadag: General rush for inoculation to avoid segregation, 23,680.
General antagonism, 18,594.
Guntakal: Fear of inoculation because of sudden death of a man after the operation, 5068.
Hinganghat: People inoculated merely to secure privileges, 6046.
Hubli: Fee paid by the people for the benefit of inoculation, 23,871.
Hubli: Popular, 3163, I. 399.
Jawalapur: No inoculation done; strenuously objected to, 9211.
Madras City: In spite of official encouragement very few people got inoculated when outbreak of plague was threatened, 3872.
Madras Presidency: Adopted before appearance of plague, 170.
Mysore City: Inoculations were pressed; about one-seventh of the population inoculated before plague broke out, 25,034.
Native States averse to inoculation or any treatment at all, 9803–4.
Panjab: One village fully inoculated before plague broke out, owing to influence of an interested leading man, 10,723–8.
Panjab: People at Banga inoculated on advice and example of their leaders, 10,172.
Poorer classes specially inoculated at Hubli, I. 408.
Satara: Karad: People inoculated to obtain right to travel, 21,123.
Satara: People at first averse from but influenced by their doctors or officials with regard to inoculation, 22,391–400.
Satara: Strong objection against inoculation, 22,155.
Surat: Inoculation mostly of Bombay refugees who were anxious to return, 15,879.
Unpopular at first, much less unpopular later, 922, 3163.

BARS TO INOCULATION WITH HAFFKINE'S FLUID.
Anæmia, persons refused who suffer from, 16,588.
Diabetes, phthisis, old age, and marked plague debar from, 1759–62.
Fever or marked plague disqualifies for inoculation, 3068.
Fever; no person with temperature of 100 degrees should be inoculated, I. 400.
Infirmity and Bright's disease bars to inoculation, 1790–1.
Malarial fevers, refused to persons with, 16,588.
None, except infants, who applied rejected at Karachi, 11,737.
Pregnancy, weak health, or certain diseases as diabetes, form a bar to inoculation, 1689–95.

INOCULATION WITH HAFFKINE'S FLUID—*cont.*

Sickly and weak persons and pregnant women not inoculated, 16,273.
Sickly infants, pregnant women, and people with fever not inoculated, 1812–4.
Weak persons dissuaded from, 12,967.

See Age and inoculation.
,, After effects of inoculation: *Pregnant women.*

CASTE, RELIGION, AND RACE, INOCULATIONS WITH REFERENCE TO:

Baroda: Table of inoculated and uninoculated according to castes and social position, II. 276.
Bajwa: Table of inoculated and uninoculated according to castes, II. 72.
Calcutta: Caste and sex and social position of inoculated, 6557.
Dhamdacha: Numbers of inoculated and uninoculated per castes, II. 268.
Europeans do not, as a rule, apply for inoculation, 1815.
Hindus persuaded to take it, 1363, 1366.
Jains, on account of their objection to anything which involves death of animals, are difficult, 7892.
Karachi: Weekly number of inoculations according to caste, II. 376.
Koili: Table of inoculated and uninoculated in the different castes, II. 270.
Low Class Cultivators: Inoculation applied for at Ankleshwar principally, 14,314.
Muhammadans offered themselves first for inoculation in Hubli, 3052.
Muhammadan soldiers at first object, 2819.
Muhammadans readily come at Calcutta, I. 476.
Muhammadans slow to take it up, 4016.
Muhammadans: Among those inoculated at Bangalore only 2163, 3482.
Muhammadans: Inoculation not resorted to at first, later more frequently resorted to in Bangalore, by 2636.
Muhammadans: Come forward to be inoculated in Calcutta, I. 476.
Muhammadans: Favour inoculation in Broach, 15,511.
Muhammadans: Set example of being inoculated in Calcutta, 6643.
Parsee gentlemen assisted in inoculation operations in Daman, I. 306.
Parsees favour inoculation in Broach, 15,511.
Parsees inoculated at Broach, II., App. LIII.
Undhera: Table of inoculated and uninoculated according to castes, II. 266.

CERTIFICATES OF INOCULATION:

Are occasionally transferred from one person to another, 25,504.
Certificates of inoculation liable to be taken from dead by relatives, 2480, 2482–7.
Certificates of single inoculation likely to be used by persons other than those to whom granted, to secure advantages of double inoculation, but not successfully, 23,872–4.
Certificates rarely sold, 2513.
Certificates very rarely transferred, 3089, I. 408.
Occasionally transferred, but nothing of the kind of a regular traffic in certificates existent, 1966–7.
Occasionally transferred, but not likely that a person should get inoculated in order to give his certificate away, 3089.
Prosecutions stop transference of certificates, 1965.
Refusal of relatives to return certificates of dead patients, 2647, 2714–5.
Thumb-marking for identification difficult in practice and an unnecessary precaution, 1965.
Transfers of certificates would, without doubt, take place if the transferor could make anything by it, 2676.
Transfers suspected in Mysore City in rare instances only, 25,040.
Where the register is kept properly there is little room for personation; it may only come in afterwards by the transfer of certificates, 1964.

DOSAGE.

Amount injected, 32–34, 72, 141, 180, 185, 1832, 10,705–6.
Average dose fixed at 2½ c.c. 33, 4002, 4577.
Children stand a larger dose comparatively, 1748, 3009, I. 400.

INOCULATION WITH HAFFKINE'S FLUID—*cont.*

Children stand proportionately much larger doses, 23,819.
Dose one-fifth more than standard dose given by Miss Corthorn, 23,812.
Experiments for obtaining a permanent immunisation by a succession of doses rapidly increasing from the minimum dose, 19,287.
Fighting weight the most important factor in standardising the dose, 3010.
Half dose used at Belgaum, 5627.
Larger dose given in cases where patient had not reacted on the first, 1751.
Uniform doses very important, 3156–7.
Uniform, dose should be more. Would save much trouble, 4064, 7889.
Use of a dose definitely known, the most important point in every vaccination, 26,449.
Women bear quite as strong doses as men, 23,813–5.

DURATION OF PROTECTION AFFORDED BY INOCULATION.

Details of cases to show that period of immunity is uncertain, II. 282.
Duration of protection probably at least 6 months, 1938.
Effects upon people living in good houses and fresh air last about 2 years, III. 43.
Investigations into the length of protection afforded by the prophylactic rendered impossible by the eagerness of the people to be inoculated over and over again, 26,436.
Newspaper statement that immunity from inoculation wears off in about 5 months, 11,760.
Period of immunity very uncertain, 15,438.
Period of immunity 6 months in the majority of cases, 23,723.
Table of plague cases among inoculated in Baroda cantonments, II. 289.
Table showing date of inoculation and of attack in Baroda, II. 282.
Table showing percentage of mortality from plague at Bulsar after inoculation had been introduced, II. 319.
Two cases admitted to Poona Hospital of bubonic plague 8 and 9 months after inoculation, 18,896.

EFFECTS OF INOCULATION WITH HAFFKINE'S FLUID:

Attacks, on Plague:

Alibag: Instances of good effects in individual cases in, 25,879.
Baroda: Table showing date of inoculation and of attacks, II. 282.
Belgaum: List of persons inoculated and list of attacks and deaths among them, III. 211–2.
Belgaum: Two cases after inoculation in the 26th Madras Infantry, 25,932.
Billimora: List of plague cases inoculated, with particulars, II. 262.
Billimora: Percentage of attacks on the total population higher among the inoculated than the uninoculated, 14,835.
Bulsar: Number of attacks among the inoculated and uninoculated about the same, but the mortality greater among the uninoculated, 19,989–92.
Cases to show the effects of the prophylactic in actually preventing plague, 19,066.
Child, the only uninoculated person in a compound, attacked by plague at Belgaum, and dies, 4021.
Daman: Persons attacked in 1897, recovered, inoculated and attacked a second time a month later, 16,554.
Did not check the disease among the Tais at Bulsar, 16,280.
Disinfecting coolies and staff inoculated with good results, 10,006–8, 10,681–6, 10,690–4, 11,769, 22,668.
Family of 13, 4 inoculated, the other 9 died of plague, 1752.
Good results of inoculation among coolies on disinfecting gangs in Karachi, 22,618.
Good results of inoculation in chawls on the Telang property, Bombay, 17,878.
Great safeguard, 18,230.
Increases resisting power, 1788.
Karachi: List of all inoculated persons who developed plague, II. 395.
Karachi: Only one case among 900 inoculated, some of them contacts, 22,671.

NOCULATION WITH HAFFKINE'S FLUID—*cont.*

Low figure of attacks and mortality in inoculated, 15,424.
No attacks among inoculated at Calcutta, 6557.
No case in 1,500 inoculated near Bellary, 4466–7.
No deaths from plague among the Barodias, Bhois, Kachhias, and Mahrattas at Billimora, 14,857.
Not a single attack among 200 inoculated kept under observation for five months, 18,519.
Of 2 men, working in a disinfecting gang under the same conditions, the uninoculated died of plague, the other, who was inoculated and nursed the patient, remained well, 10,681.
One person only out of 500 inoculated developed plague symptoms, 17,907.
Only uninoculated person in family of sweepers gets plague, 2776.
Percentage of recoveries, inoculated and uninoculated, in pneumonic plague, 2382.
Plague cases among inoculated 6 days after injection, 15,421.
Poona: No cases of death from plague among the inoculated, 12,971.
Preventive against plague, 10,866.
Protective remedy, 1059–60.
Protects those in contact with plague cases, I. 399.
Report of cases of plague among disinfecting gang inoculated with Haffkine's fluid, 10,006.
Summary of observations on 2 groups of inoculated and uninoculated persons, 23,809.
Two tables showing particulars of cases after inoculation, II. 153.
Table of plague cases among inoculated in Baroda cantonments, II. 289.
Table showing percentage of mortality from plague at Bulsar, after inoculation had been introduced, II. 319.
There is no such thing as complete immunity, 27,375.
Three cases in which plague appeared 10 days after, 14,941.

Clinical Symptoms of Plague, On:

Cases among the inoculated of a milder type, 1843.
Cases of inoculated so mild as to be almost unrecognisable, 69.
Clinical history of 3 inoculated plague cases. Two recover from very mild attacks, 7236.
Delirium and aphasia very rare in cases among inoculated, 14,977.
If plague follows, symptoms among inoculated are of much milder type, 1869, 23,696.
Inoculation seems greatly to modify the symptom of subsequent plague, 69.
Plague among inoculated milder than in uninoculated, 14,997.
Plague among the inoculated at Bulsar was of an attenuated type, 16,307.
Plague cases milder in inoculated, 75, 1869, 2892.
Pneumonic plague little influenced by inoculation, 2382.
Temperature not high and less exhaustion in inoculated cases, 1843.
Two cases describing course of disease in inoculated, I. 383.

Incubating Plague, On:

Cannot arrest symptoms developed very soon after inoculation, 44.
Favourable effect on incubating plague, 1772.
May influence for good course of disease when injected during incubation, if infection has taken place 3 or 4 days previously, 45.
Powerless to arrest incubating plague, 36.
Probably harmful in plague cases of short incubation, I. 400.

Mortality, On Plague:

Apparently saved a number of people from dying, but did not prevent plague from spreading, 24,447.
Bangalore: Relative mortality of inoculated and uninoculated patients in hospitals, 2917–8.
Bulsar: Number of attacks among the inoculated and uninoculated about the same, but the mortality greater among the uninoculated, 19,989–92.
Keeps down the mortality of plague, 16,282.
Miss Corthorn's table of plague death-rate among inoculated and uninoculated at Hubli, I. 76–7.

INOCULATION WITH HAFFKINE'S FLUID—*cont.*

Multiple buboes: In Baroda 60 per cent. of multiple bubo cases recovered among the inoculated, 14,997.
Rate of mortality reduced, 15,426.
Reduces mortality from 80 to 90 per cent., 78.
Sixteen out of 18 cases recover in Bombay after inoculation, 49.

Other Diseases, On:

Appears to protect from disease generally, I. 338, I. 400.
Asthma relieved, 4872, 17,963, 19,303–5.
Cases to show the beneficial effect on the general health, 19,055.
Dyspepsia, improves appetite, 4870.
Eczema relieved, but lupus and tuberculosis aggravated, I. 400.
Effects of inoculation on other diseases, 198–9, 201, I. 340, III. 43.
Fever, chronic, relieved, 17,916, 17,963.
General health much improved after inoculation, 25,443–5.
Gout milder and at longer intervals after inoculation, 25,459.
Headache, chronic, cured, 17,809.
Hemicrania, relieved, 16,631.
Instance to show its effect on other disorders, 17,912–5.
Leprosy, anæsthetic, marked improvement, 14,827.
Lumbago relieved, 199, 17,916.
Malarial fever, good effect on quartan, 199, 14,824.
May have general prophylactic effect against other diseases, 198–9.
Neuralgic pains, dissipated, 201, 14,824.
Old complaints revived, 201, 16,627.
Parametritis, revived by, 16,628.
Polyuria, good effect on, 14,826.
Rheumatism revived, 201, 16,627.
Ringworm disappeared, 14,827.
Statistic evidence does not prove that the plague prophylactic confers immunity against other diseases, 26,441.
Venereal diseases benefited, 22,402.

On Spread of Plague:

Alleged spread of plague in Daman owing to the use of Haffkine's fluid, 18,698–707.
Alleged spread of plague in Dharwar owing to use of Haffkine's fluid, 18,684–98.
Alleged spread of plague in Undhera owing to use of Haffkine's fluid, 18,707–13.
Infection carried through an inoculated person who himself remained free, 10,753.
Inoculated persons are not a source of danger to the uninoculated, 14,977.
Inoculated persons do not spread the disease, I. 408.
Not prejudicial to the uninoculated, 24,112.
Produces an increase in mortality among the uninoculated, 18,703.
Table in support of allegation that increased mortality at Daman followed inoculations, III. 65.

EXTENSIVE APPLICATION, WHEN RESORTED TO, AND GENERAL RESULTS OF:

At first applied only where epidemic was severe, 165.
Cannot be done quickly enough to stop epidemic, 7990.
Cannot be carried out on same scale as vaccination, 7982.
Five hundred inoculations a day a fair average, 4079.
Produces good results mainly through the feeling of safety it provides, 23,680.
Inoculation in Karad and Belgaum commenced when plague was practically over, 21,121, 25,930.
Not general until plague becomes epidemic, 88.
People refrain until panic-stricken, 4476.
Prevents disturbance of trade, 1956.
Useful as a means of allaying the dread of plague, 16,096.

HISTORY OF INOCULATION, IN:

Alibag: Inoculations in the beginning of 1899, with particular instances of its protective effects in individual houses, 25,878–91.
Ankleshwar: No positive results as to the value of inoculation at, plague dying out when commenced, 14,250.

INOCULATION WITH HAFFKINE'S FLUID—*cont.*

Ankleshwar: Of 645 inoculated persons in, 4 died from plague, II. 242.
Ankleshwar: Statement of inoculations with Haffkine's fluid at, II. 240.
Baroda Cantonments: Plague occurrences among the inoculated and the uninoculated, 15,426.
Baroda Cantonments: Native troops refused inoculation, 15,435.
Baroda Cantonments: Register of persons living in cantonment maintained: total population 4,000: two thousand and forty-eight were inoculated: the balance reckoned as uninoculated, 15,401, 15,406, 15,475.
Baroda City: Figures relating to inoculation in, 14,986–8.
Baroda State: Evidence and report on inoculations, II. 261–78, II. 503–21.
Belgaum: Eleven thousand persons inoculated in I. 202–3.
Belgaum: Inoculations began in December 1897, 3,447 persons inoculated in the district, results of inoculation, 23,131–56.
Belgaum: Major Forman's evidence regarding inoculations among his servants, 23,787–9, 23,102–9.
Belgaum: Major Forman's evidence regarding inoculations among hospital servants, 23,797–9, 23,809.
Belgaum: Number of plague casualties among inoculated not ascertained by inquiries at the time but by reference to registers which were very defective, 22,929–36.
Belgaum: Registers very inaccurate; instances of omissions, 23,079–102.
Belgaum: Two thousand five hundred and sixty-five persons inoculated in the city, 23,133.
Belgaum: 26th Madras Infantry: Plague occurred on 12th November 1897, and inoculations commenced on 23rd December, when outbreak near its close: only two inoculated attacked, 25,927–33.
Belgaum: 26th Madras Infantry: Second outbreak: On reappearance of plague the regiment re-inoculated at the men's request between 18th and end of August, only men away being uninoculated, 25,940–2.
Belgaum: 26th Madras Infantry: Second outbreak: Lieutenant Lethbridge with the regiment from 5th September to 15th October 1898, and inoculated everyone in it, 5617–21.
Belgaum: 26th Madras Infantry: Second outbreak: Re-inoculations began 10th September, and were done in 10 days, 5625–6.
Belgaum: 26th Madras Infantry: Second outbreak: Lasted from July to December: Major Bannerman's details of cases, 25,934–8.
Belgaum: 26th Madras Infantry: Second outbreak: Lieutenant Lethbridge's statement of cases in September and October, 5621–6.
Broach: Encouraged by native practitioners, 15,504, 15,510.
Broach: Inoculations, chiefly among the Parsees, 15,511; II. 522–3.
Broach: Kantiajal: Good results of, at, 15,505.
Bulsar: Census taken and statistics carefully checked, 16,288, 16,296–306.
Bulsar: Comparison between inoculated and uninoculated Tai wards, 16,280–1, 19,970–94.
Bulsar: Comparison between inoculated and uninoculated Ghanchi wards, 16,287.
Bulsar: History of inoculations in Bulsar, 16,255–341.
Bulsar: Inoculations performed to see to what extent they would stop plague, 75.
Bulsar: Inoculated did not leave the place but uninoculated persons did so, 16,291.
Bulsar: Table of results of inoculation, 16,256, 16,277; II. 320.
Dharwar: Cases among inoculated and uninoculated in camp recorded only if found in the town, 1988, 1991, 1996, 2351–8.
Dharwar: Deaths among people who left the town and camped outside not included in inoculation returns, 1976.
Dharwar: Inoculations recommended on the outbreak of plague, 1974.
Dharwar: Most people in the town inoculated, the people in camp being the large majority of the town population not inoculated, 1956, 1974–9, 1991–4, 2351.

INOCULATION WITH HAFFKINE'S FLUID—*cont.*

Dharwar: Report on plague cases among inoculated, I. 429–38.
Dharwar: Statistics of inoculation and plague, I. 67.
Dharwar: Statistical comparison by Miss Corthorn of inoculated and uninoculated, 1763–71.
Dharwar: Whole population inoculated in, except sick and aged, 1689.
Dharwar District: Inoculations at Huilgol, II., 226.
Dharwar District: Inoculations at Lingdhal, III., 225.
Dharwar District: Villagers desired inoculation and were permitted to be inoculated, 1958–61.
Dharwar Jail: All prisoners in inoculated successfully, 2263–4.
Gadag-Betigeri: Classification of doubtful cases as inoculated or uninoculated done by Mr. Foy, 23,837, 23,863.
Gadag-Betigeri: Inoculations done on a large scale, 23,680.
Gadag-Betigeri: Miss Corthorn's figures obtained from official statistics supplemented by independent inquiry, 23,837–9.
Gadag-Betigeri: Miss Corthorn's statistics of inoculation, 23,831.
Gadag-Betigeri: Mr. Foy's statistics of inoculation, 23,727.
Hyderabad State: Not introduced at, 5159, 5511, 18,141.
Madras: Efforts to introduce in, 3871–2.
Mora: Statistics of inoculation, 52, 27,310–8.
Mysore City: Census not taken, and extent of exodus not determined, 24,977.
Mysore City: Large numbers inoculated before plague broke out, 3482.
Mysore City: Statement of inoculations at, III. 277.
Mysore City: Statistics checked by inquiries but not very accurate, 25,037.
Mysore City: Statistics of attacks and deaths among inoculated probably correct, 25,112–5.
Mysore State: Evidence on inoculations of the native troops, I. 177–9.
Panjab: Banga: Details of, in, 10,172–7.
Panjab: Banga: Prophylactic inoculations done in, on a large scale, 10,235.
Panjab: Garhshankar: Inoculations in, 10,674–8, 10,861.
Poona Lunatic Asylum: Inoculations performed partly as a preventive and partly as an experiment, 12,841.
Satara: Gave very good results, 22,156–61, 22,390.
Satara: Seven hundred and eight persons inoculated, 22,390.
Satara: Six hundred and ninety-one persons inoculated in the city, 22,154.
Satara: Statistics of inoculation in the district, 1898–99, III. 190.
Surat: Not tried at, 2061.
Umreth camp: Inoculations on a large scale in, but the existing conditions offer no fair test of its efficiency, 14,088.
Wardha: Evidence on plague cases and inoculations at, I. 225–7.

IDENTIFICATION OF BODIES OF INOCULATED PERSONS:

Bangalore City: Identification of dead thrown into the streets difficult, 3522.
Bangalore Civil and Military Station: Identification in doubtful cases difficult, and depends on inquiries, 2615–6.
Hubli: Dead bodies classed as inoculated or not after careful inquiry; tendency of people to assert that uninoculated dead have been inoculated, 1726.
Hubli: Half the dead found in the streets had inoculation certificates on them, 3093.

INOCULATION WITH HAFFKINE'S FLUID—*cont.*

Hubli: Inoculation register had no index, 2528.
Hubli: Method of registering deaths. Over 95 per cent. of bodies identified I. 400, 409.
Hubli: No difficulty in identifying the dead as inoculated or not by register and certificates, 1964–5.
Hubli: The unidentified dead classed as inoculated or not according to the proportion of each class shown by the census to be in the town, 3082–4, 3131–7, 3181–2.
Hubli: Statistics assume a man inoculated if no certificate is found, 2473–7, 2515–6, 2530.
Mysore City: Inquiries made and certificate recovered if possible, but margin of error remained, 25,038–9.

INDUCEMENTS TO INOCULATION WITH HAFFKINE'S FLUID:

Alibag: Inoculates allowed to remain in their houses and go where they like, 25,880, 25,883.
Bangalore City: In houses, where all inmates inoculated, neither sick nor contacts removed, 3292.
Bangalore City: Privileges for inoculated same as at Hubli, 3298–9, 3315–6.
Bangalore Civil and Military Station: Contacts from going to camp, inoculation exempts, 2637.
Bangalore Civil and Military Station: Contacts not evacuated at Bangalore if inoculated, 2576.
Bangalore Civil and Military Station: Inoculated contacts allowed to remain in their houses, if good, otherwise to go where they please, 2637, 2661–4.
Bangalore Civil and Military Station: No restrictions on the movements of the inoculated, 2637, 2661.
Baroda State: Inoculated persons not forced to vacate their houses in the villages of Baroda State, 15084.
Baroda State: Passes offered in the Naosari district as an inducement, 15,071.
Belgaum: Privileges to inoculated at Belgaum, 23,132.
Bombay: Certificates given to inoculates which passed them on railways. Not treated as contacts, 1366.
Bombay: Contacts given the option between inoculation and removal to camp, 17,878.
Bulsar: Concessions in the way of treatment of sick in their own houses, &c. given to the inoculated, 16,291.
Calcutta: Inoculated persons practically free of all plague measures, 6537–9.
Calcutta: Segregation, inoculated families promised freedom from, I. 468.
Dharwar: Concessions granted to inoculated persons in the matter of return to evacuated houses, 2337, 23,746–7, 23,763–6.
Discomforts of plague measures, people would submit to inoculation to avoid the, 10,727.
Hubli: Certificate to enable travelling without detention and short time of segregation induced the people in Hubli to submit to inoculation, 2428–34.
Hubli: Inoculated persons re-admitted to evacuated areas after 10 days, 1955.
Hubli: Inoculation encouraged by moral suasion and grant of privileges, 2471–2, 3055, 19,889.
Hubli: Method of persuading people to inoculation at Hubli, I. 398–9.
Hubli: No rule prohibiting non-inoculated from re-occupying their houses, but they could not travel by road or rail, 3158–9.
Hubli: People induced to submit to inoculation by the offer of privileges, 19,826–8, 19,888.
Hubli: People not allowed to return from segregation to infected places unless inoculated, 2432–3.
Hubli: The once inoculated had no privileges in segregation, 3164.
Hubli: Twice inoculated persons allowed to return to their houses at once after disinfection, 23,375.
Karachi: Inoculates not segregated, II, 423.
Karachi: Only inducement that inoculates were not turned out of their houses, 11,756.
Mysore City: Number of people probably inoculated in order to leave the place, as facilities for travelling granted to inoculates, 25,108.

INVESTIGATION SHEETS:

Banga: Tables of inoculated and uninoculated persons in the houses attacked with plague, II. 91–93.

INOCULATION WITH HAFFKINE'S FLUID—*cont.*

Baroda State: Manner in which investigation sheets prepared, 15,040–54.
Belgaum: Investigation sheets of four houses in Belgaum prepared by Colonel Peters, I.M.S., 23,108–15.
Billimora (Baroda State): Table of inoculated and uninoculated in the same houses, II. 263.
Daman: Particulars of households where inoculation was applied and plague occurred, I. 310–30.
Hubli: Investigation sheets prepared from cases selected by Lieutenant Keelan as good cases, 19,877–88, 19,899–906.
Hubli: Investigation sheets selected from 200 cases collected and investigated by Lieutenant Keelan, 19,829–35.
Hubli: Investigation sheets, 60 cases appended to Leumann's Report selected by him from 200 cases picked and chosen for him by Lieutenant Keelan, 1725.
Hubli: Plague cases (house by house) in inoculated houses, I. 417–28.
Kantharia (Baroda State): Investigation sheets synopsis, II. 506.
Karachi: Details of plague cases in houses inhabited by inoculated persons, II. 428–42.
Koili (Baroda State): List of cases with particulars among inoculated, II. 269.
Koili (Baroda State): Table showing the results of inoculations, II. 277.
Undhera: Cases among inoculated and uninoculated, house by house, I. 333–6.
Undhera: Summary by houses of plague cases, I. 331.

METHOD OF PERFORMING INOCULATIONS:

An operation requiring very little skill, 178.
Place generally in left arm, rarely flank, 1,746–7.
Precautions for cleaning inoculating instruments, 1752.

PERIOD AFTER WHICH PROTECTIVE EFFECT EXERTED:

Acts in from 12 to 24 hours, 144.
Affords some protection from first day, 1774.
Beneficial within 24 hours, 47.
Protection begins in 24 hours, 4024.
Rapidity of action, 47.

PERSONS RECOVERED FROM PLAGUE; INOCULATION OF:

Reaction does not differ from that in persons who have not had plague, 1537.
Recovered plague cases not inoculated, 2504.

REACTION AFTER INOCULATION OF HAFFKINE'S FLUID:

Amount of:

Above 103° not observed after inoculation, 14,319.
Above 104° not observed after inoculation, 14,520.
Average temperature, 103°, 16,571.
Average resulting temperatue, 101·8°, 778.
Between 100° and 103°, 12,398.
Higher in men than in women after inoculation, 23,813.
Highest 24 hours after inoculation, 10,796.
Inoculation of the 26th Madras Infantry gave so little discomfort that they submitted willingly to a second, and were anxious for a third, 25,942.
Maximum after inoculation, 102½°, 32.
No excessive reaction observed, 6338.
Reaction temperature after inoculation ought not to be less than 102°, 3006.
Subnormal after, 20,471.
Some of the doses did not give enough febrile reaction, 2996.
Temperature aimed at after inoculation 102½, 32.

Animals, In:

Effect of injection into animals, 28, 29.

Europeans, In:

Europeans suffer more than natives from, 4858–9.
Produces stronger reaction in Europeans than in natives, 4858–9.

Old Men, In:

Small doses given to old persons and little children give very little reaction, 25,891.

Particular Instances, In:

Bangalore: Maximum temperature resulting 104°, 4837.
Baroda: Highest temperature 104, 15,417.

Inoculation with Haffkine's Fluid—*cont.*

Bombay: Byculla Jail: Did not react on several of the prisoners in, 20,365.
Bombay: Byculla Jail: Prisoners suffered severely from, 20,364.
Bombay: Umarkhadi Jail: Its discomforts did not last beyond 36 hours, 20,315.
Calcutta: Highest temperature observed, 105°, 6663.
Hubli: Temperature obtained 106°, 2000.
Karachi Jail: Highest temperature 104°, lowest 99° after, 11,563–4.
Mr. Haffkine: Effect of inoculation on, 32.
Wardha and Nagpur: Report of 201 inoculations in, with special reference to the reaction produced, I. 460–1.

Persons recovered from Plague, In:

Reaction in those recovered from plague not in any way different, 1537.

Re-inoculation, After:

No diminution in the severity of the reaction after three subsequent inoculations, 19,050.
Second inoculation, effect more severe, 6626.
Temperature reaction about the same as in the first, 23,820.

Variety in:

Great variation in the general symptoms after, 11,573.
Great variety in different views, 6330.
Reaction sometimes too slight, sometimes excessive, in Calcutta, 6622–4.
Standard dose does not produce the same symptoms in each healthy individual, 5095.
Varies with individuals after same doses; ideal temperature 102°, 76, 10,797–800, 17,490–5.
Varying after inoculation of the inmates of the lunatic asylum, 12,963.

See After effects of inoculation, *fever and severe symptoms from.*

Re-inoculation.

Attitude towards:

People generally object to second inoculation, 10,166.
Second inoculation would make process unpopular, 4062.

Dharwar:

Dharwar: Measures adopted for the re-admission to the town of the people only after double inoculation, 23,746–7.
Dharwar: One hundred thousand people inoculated, nearly all twice, 25,163.

Dose:

Larger dose given in cases where patients had not reacted on the first, 1751.

Effect of:

Effect of second inoculation less marked locally than that of first, 111.
Second inoculation, effect more severe, 6626.
Temperature reaction about the same as in the first, 23,820.

Hubli, At:

Comparative death-rate of inoculated (once or twice), I. 401–6.
Double inoculation recommended in all cases, 3164, 3187.
Effects of re-inoculation at Hubli, 70.
Second inoculation benefits in Hubli by 10 per cent., I. 407.
Second inoculations have no obvious effect at Hubli, 72.
Statistics with regard to second inoculation at Hubli, I. 404–6.

Inducements to:

Bangalore: For obtaining a pass by rail or road at Bangalore it was necessary to show a certificate bearing date of second inoculation 10 days previous, 3159.
Gadag: Once inoculated have no advantages, and double inoculation only confers privileges, 23,864, 23,869.
Hubli: Once inoculated persons had no privileges, 3164.

Inoculation with Haffkine's Fluid—*cont.*

Hubli: Twice inoculated persons given passes permitting them to travel, 1687.
Hubli: Twice inoculated persons not segregated, 19,826.
Hubli: Twice inoculated persons allowed to reoccupy houses directly after their disinfection, 23,375.

Interval between 1st and 2nd Inoculation:

Second inoculation from 7 to 10 days after first, 1749.
Three days shortest interval between first and second inoculation, 4008.

Plague after:

European case after twice inoculation with Haffkine's fluid in Poona, 21,293.
European soldier contracts plague after having been inoculated twice, 21,293.
Instance of Banniah three times inoculated died of plague, 16,669.
No person known to have had plague after twice inoculation, 11,772.
Person twice inoculated dies of plague, 22,936.

Reasons for:

Bacteriological ground for re-inoculation shown by agglomeration and bactericidal effect of blood of twice inoculated persons, 3187–216, I. 398.
Ideal method, double inoculation, first with a trial dose, 77.
Reasons for inoculating twice, 3038.
Two operations advisable, first dose as a means of testing, 1482.

Standardisation of Dose:

Control experiments not always made by inoculators to standardise the doses, 3023–8, 6321, 10,803–7, 11,702–3, 14,808–11.
Dose found too weak at Hubli on account of observations of reactions produced and increased, I. 398.
Estimate of dose obtained from the reaction observed in inoculated, 26,466.
Holding up the bottle to the light is not an effectual method for the standardisation of the fluid, 26,485.
Individual physical conditions a guide to the standardising of the dose, 19,279.
Microbe of known virulence, the use of a, and an absolutely aseptic vaccine the necessary factors in, 26,488.
Microbe employed in cultivation and quantity of vaccine, connexion between virulence of, 58.
Mr. Haffkine's instructions that each inoculator should watch the first 10 or 20 patients of each new series of inoculation, and standardise by results produced by them, 78.
No difficulty in standardising dose by using standard fixed in laboratory raised according to indications obtained from observations of reaction in persons coming for re-inoculation, 1743.
Severe symptoms not always corresponding with a rise in temperature, 11,574.
Standard dose 2½ c.c., 72.
Standardising of the fluid not practicable under ordinary circumstances by observing test cases, 10,807.
Some of the doses did not give enough febrile reaction, 2996.
Strength of dose tested experimentally on control cases, 2999.
The standard of its efficacy is based on the reaction it produces, 26,494.
Weighing of the sediment considered not a satisfactory method for standardising the fluid, in view of the fact that the intention is to standardise by temperature reaction, 26,472–81.

Statistics relating to Inoculation:

Errors of:

Exclusion from inoculation of the very old and very young may account for the higher percentage of deaths among uninoculated, 17,808.
Uninoculated people coming to die in the town may corrupt statistics, 2356.

Plague and Inoculation:

Bangalore: Statistics of troops, I. 114–5, I. 165–75; III. 281–7.
Bangalore and Mysore: Statement of weekly number of inoculations from September 2nd, 1898 to February 28th, 1899, III. 276–7.

INOCULATION WITH HAFFKINE'S FLUID—*cont.*

Baroda: Bajwa: Weekly gross mortality from plague among inoculated and uninoculated after February 18th, 1898, II. 272.
Baroda: Billimora: Table of gross mortality from plague after introduction of inoculation, II. 265.
Baroda: Billimora: Statement of inoculated and uninoculated with results per castes, II. 263.
Baroda: Billimora: Table of inoculated and uninoculated according to age, II. 265.
Baroda: Billimora: Table of inoculated and uninoculated according to castes, II. 504.
Baroda: Billimora: Table of weekly gross mortality from December 20th, 1896, II. 264.
Baroda: Billimora: Table of weekly gross mortality from February 3rd, 1898, II. 264.
Baroda City: Weekly gross mortality from causes other than plague amongst inoculated and uninoculated, II. 275.
Baroda City: Table of weekly gross mortality among inoculated and uninoculated, II. 275.
Baroda: Dhamdacha: Statistics of inoculations, II. 267.
Baroda: Dhamdacha: Table of gross mortality for three months previous to the first epidemic, II. 268.
Baroda: Dhamdacha: Table of gross mortality for three months previous to the second epidemic, II. 268.
Baroda: Dhamdacha: Table of gross mortality for three months previous to the third epidemic, II. 268.
Baroda: Dhamdacha: Table of gross mortality from plague and other causes during the three epidemics, II. 268-9.
Baroda: District Villages: Table of results of inoculations, II. 273.
Baroda: Gandevi: Gross mortality from causes other than plague amongst the inoculated and uninoculated, II. 272.
Baroda: Gandevi: Gross mortality from plague and other causes from January 28, 1898, II. 271.
Baroda: Gandevi: Table of gross mortality from plague and all other causes from December 25th, 1896, II. 271.
Baroda: Kadi District Villages: Details of inoculations, II. 274.
Baroda: Naosari District: Details of inoculations in the villages, II. 273.
Belgaum: List of persons inoculated and list of attacks and deaths among them, III. 211–2.
Belgaum: Table of occurrence of plague in house inhabited by persons inoculated against plague, III. 209.
Bulsar: Table of gross mortality from plague and other diseases among inoculated and uninoculated, II. 320.
Bulsar: Table of particulars as to locality, attacks, and deaths from plague and other causes, II. 318.
Deaths among inoculated two per cent., uninoculated 70 per cent., 25,429.
Dharwar and Hubli: Death-rate of uninoculated, 9 and 14 per cent. respectively, 1727.
Dharwar: Miss Corthorn's table of plague death-rate among inoculated and uninoculated, I. 76-7.
Dharwar: Table of results, I. 67.
Gadag-Betigeri: Table of attacks and deaths from plague, II. 234.
Gadag-Betigeri: Weekly census of the number of uninoculated, once inoculated, and twice inoculated, III. 238.
Gadag-Betigeri: Weekly census of plague incidence among uninoculated, once inoculated, and twice inoculated, III. 239.
Hubli: Course of plague and inoculation, I. 65.
Hubli: Discrepancies in statistics, 3056–65.
Hubli: Statistics, 1819–24, 25,151.
Hubli: Table showing inoculation and death statistics, I. 65.
Karachi: Table of gross mortality from plague and other causes, II. 151.
Karachi: Table of weekly number of inoculations, II. 375.

STRENGTH OF HAFFKINE'S FLUID:

Comparison of cases inoculated at Daman with doses of different strength, I. 309.
Effect of weak vaccine in Daman and Kirki, 72.
Inferior vaccine at Kirki and Lanauli, 184–90.

INOCULATION WITH HAFFKINE'S FLUID—*cont.*

Least successful at Kirki, where vaccine weak, 68, 75, 119.
Lower average of temperature after inoculation at Kirki and Lanauli, 184–8.
Variety in strength of brew inevitable, 72.
Weaker fluid or smaller doses reduce protection, I. 307.
Weaker vaccine in larger doses does not give as powerful a reaction as a stronger vaccine in small doses, 27,257.

INSECTS:

Flies, fleas, bugs, and mosquitos not agents in spreading plague in the Arthur Road Hospital Bombay, 20,640–1, 20,999–21,004.

See Ants.
„ Bugs.
„ Fleas.

INTERVAL BETWEEN INTRODUCTION OF PLAGUE AND EPIDEMIC:

Cases illustrating a long interval between arrival of imported cases and the first indigenous case, 10,223–4.
Interval in the case of Aur, 10,224, 10,549–53.
Interval in the case of Bobleshwar, 19,513.
Interval in the case of Dahan, 10,091, 10,224.
Interval in the case of Gobindpur, 10,224.
Interval in the case of Igatpuri, 19,509.
Interval in the case of Ilkal, 19,512.
Interval in the case of Kajurgi, 5501.
Interval in the case of Khatkar Kalan, 9919–30.
Interval in the case of Mahlgahla, 9987, 10,348.
Maps prepared to show intervals in Bombay, but not strictly accurate to say that time between first imported and first local case is the time it takes to make a place infected, 17,135.
No hitherto published theory sufficient to explain the fact of the long interval between the first importation of plague and the general outbreak, 8566, 8630.
Plague possibly temporarily dormant on first introduction, 214–5, 295.
Three weeks the period between the importation of a plague case and the actual outbreak, 19,512.

INVOLUTION FORMS OF BACILLUS OF PLAGUE:

Animals, in:

Involution forms of plague bacilli seen after death at the seat of inoculation in a cat and guinea pig, 26,227.

Development of:

Bouillon, involution forms not developed in, 8718.
Salt agar, involution forms will develop in 24 hours if kept in the incubator, in cultures with, 8717.
Salt added to the agar-agar causes the involution forms to develop very rapidly, II. 4; 8599.

Human Body, in:

Human body, involution forms found in, and appear to be a post-mortem change, I. 376.

Test of culture:

Development of involution forms a practically valuable test whether or not the culture is of plague, 8668.

Toxic power:

The toxic power of the microbe attenuated through the effects of involution, 8520.

Variety of:

In cultures of plague the involution forms are more distinct in older than younger bacilli, I. 376.
Involution forms are very common where the cultivation media are not absolutely suitable, 27,327.
Size and involution forms vary considerably in different growths, and individuals of the same growth, 26,402.

ISOLATION OF PLAGUE BACILLUS:

Difficulties of:

Details of experiment for the discovery of the plague bacillus, I. 139–40.
Difficulties of search, 8510–13.
Difficulty of detecting the bacillus in articles examined owing to rapid growth of contaminating micro-organisms, 26,341, 26,391.
Inoculation into rats best method of testing for presence of plague, 697.
No method for identifying the microbe in articles of clothing, mud, or cow-dung, 8537.
No method for identifying bacillus outside plague patient or plague rat, 151.

See Carbonic acid gas.
,, Cultures.
,, Hankin's method.
,, Hydrogen.
,, Inoculation of plague virus.
,, Microscopic appearances.
,, Staining.
,, Stalactite formation.

In Animals:

Animals can die of plague without the microbe being discoverable in their bodies after death, 8613.
Ants: Not found in ants, 635, 8530.
Cattle: Diplo-bacteria similar to those found in plague rats discovered in the blood of cattle during the epidemic at Calcutta, 1897, 26,942.
Cat and guinea-pig: Involution forms of plague bacilli seen after death at the seat of inoculation in a cat and guinea-pig, 26,227.
Cats: Found in cats with typical plague symptoms, 20,424.
Fleas: Not found in fleas, 8600.
Fleas: Said to be found in fleas, 151.
Guinea-pigs: Found in the intestines of a guinea-pig, 27,336.
Guinea-pigs: Easily discovered in the bronchial contents of guinea-pigs in laboratory experiments, 27,341.
Recoverable from body of dead animals up to 21 days after burial, 27,382.
Leeches: Isolated from leeches which had been applied to buboes, 22,287.
Mice: Spleen and liver of mouse dead of plague found full of plague bacilli, 26,324.

See Rats.

In the Human Body:

Bronchi: Found in the bronchi, 6916.
Kidneys: Found post mortem in kidney I. 370.
Lesions: Found in four cases in small lesions of the skin, 1393.
Lesions: Cultures obtained from small lesions; blood remained sterile, I. 374.
Liver: Found in liver of plague corpses, 7189.
Liver: Found post mortem in liver, I. 370.
Nose: Found in the bloody discharge from the nose in patient of sub mental buboes, 26,259.
Saliva: Found in saliva of ordinary bubonic cases occasionally, once 10 days after apyrexia, 25,355.
Spleen: Found in spleen of plague corpses, 7189.
Spleen: Found post-mortem in spleen, I. 370.
Sweat: Never discovered in sweat, 26,393.
Throat: Found in the throat 10 days after fever had subsided, 25,312.
Tongue: Found twice in the fur at the back of the tongue out of 20 cases, 27,055.

See Blood.
,, Carbuncles.
,, Fæces.
,, Glands.
,, Lungs.
,, Sputum.
,, Urine.

Outside the Animal Organism:

After several months' work only found in one case outside of patients in salt water in a pond, 8510.
Not detected outside plague patients, 153.

ISOLATION OF PLAGUE BACILLUS—*cont.*

Once found in soiled matting which had been used as bedding, 25,394.
Results of experiments with suspected substances of human and animal origin, II. 15.

See Clothes.
,, Grain.
,, Merchandise.
,, Soil.

ISOLATION OF THE SICK:

In small-pox and other diseases natives recognise value of, and enforce isolation of the sick, 7,038.
Isolating the sick most necessary, 12,053–5, 13,191, 21,540.
Isolation of the sick imperfectly carried out by people in camps in Sind, 11,894.
Isolation of the sick, &c., did not stop the progress of the disease at Baroda, 14,604.
Isolation of sick, one of measures applied in the Panjab, 10,450.
Plague-stricken at Nasik at once taken to plague camp, 13,764.
People alive to the benefit of isolating the sick in Karachi, 11,378.

See Removal of the sick to hospital.
,, Treatment of the sick in their own houses.

ISOLATION OF THE SICK IN THEIR OWN HOUSES:

See Treatment of the sick in their own houses.

IZAL:

Action on bubonic microbe, II. 5.
Izal 1 in 300 capable of killing the plague bacillus in 3 minutes, 27,401.

JAINS:

Jains among the first to suffer in Bombay, 911.
Jains had the highest mortality rate in Bombay, this being due to the fact that animal life is sacred among them, 17,681.
Jains, on account of their objection to anything which involves the death of animals, are difficult to deal with with respect to inoculation, 7,892.

See Banniahs.
,, Habits of people affecting liability to plague.

JEYES' FLUID:

Disinfection by:

Clothes of passengers entering Karachi by sea disinfected with Jeyes' fluid, 4243.
Jeyes' fluid in strong solution enough to kill bacillus would hurt people so much that they could not stand it, 4305.

KARACHI:

Inoculation with Haffkine's Prophylactic:

Inoculated left the city, but not more than uninoculated, 11,756.
No roll call or anything of that sort in the voluntary camps, 11,374, 11,879.
Population during period of inoculation arrived at by approximate estimate, 11,713–7, II. 424, 11,804.
Report on the effects of inoculations, II. 375–97.
Results on prisoners negative, as plague ceased in the city at the time of inoculation, 11,548.
Summary of results of inoculation, 11,758, 11,765, II. 424–5.
Statement of results of inoculation among the people, 11,758-65.
Statistics of inoculation to be accepted with caution as population of Karachi during plague not accurately known, 11,765, II. 425.

See Khoja Community.

Introduction of plague into:

First case came to notice on 10th December 1896, other cases being detected immediately afterwards, and no connexion between the earliest cases being traced, 11,092–3, 11,099, 11,101, 11,846.

KARACHI—*cont.*

First case occurred in a good quarter, in a person who had had no direct communication with Bombay, 11,096, 12,984, 13,216.
Gunny bags: Asserted to have been the means of importation of plague into Karachi, but no proof of assertion, 817.
Gunny bags: Examined, but no traces of plague found in them, 635.
No plague in Karachi between the first and second epidemics; authorities confident that the city was quite free, 11,183.
Rats or cargo probable means of first importation of plague by sea from Bombay to Karachi, 12,984.
Sea: Disease must have come to Karachi in 1896 by sea from Bombay, 11,338.
Sea: Strict precautions taken against importation of infection by sea between the first and second epidemics at Karachi, 11,598, 12,151, 12,218, 12,317–8.
Second epidemic: First cases at end of March 1899, no connexion traced, 11,181, 11,512–22.
Second epidemic: First case in quarter not infected in first epidemic, in person of a man working at the Native Jetty, hence assumption that infection imported in cargo, 13,215–6, 13,220.
Second epidemic: Rats died before the first case came to the notice of the authorities, 11,198, 11,308.
Second epidemic: Joria Bazar infected, no connexion traced with first case occurring in a different part of the town and no source of infection ascertained, 11,188, 11,197–200, 13,344.
Suspicious cases between the first and second epidemics, 11,599–610, 11,611–2.

Statistics relating to:

Population estimated at 130,000 at the time of the first outbreak, 11,071.
Statistics of death-rate for the period between the two epidemics compared with three other towns in Sind, II. 142*a*.
Weekly number of plague cases and deaths from March 17th to November 4th, 1898, II. 424.

KHOJA COMMUNITY.

Inoculation with Mr. Haffkine's prophylactic in the:

Khoja community: The low rate of mortality from general causes in the inoculated probably due to unconscious selection of cases for inoculation, 26,500–3.
Khojas in Poona inoculated at H.H. the Aga Khan's house, 12,965.

Bombay Khojas:

Comparability of the inoculated and the uninoculated, 199.
Deaths and inoculations at different ages in the Khoja community of Bombay, 17,845.
Figures for the Khoja community, Bombay, obtained from the Jamaat books which are most accurate, 17,846–51.
Inoculations among the Khojas of Bombay, 17,793–822.
Inoculations in the Khoja community of Bombay, 69, 90.
List of inoculated Khojas treated in the Khoja Hospital, Bombay, III. 404–6.
Nominal roll of inoculated and uninoculated Khojas in Bombay who died of plague and other diseases from April to December 1898, III. 399–403.
Report by Mr. Haffkine on inoculations in the Khoja community of Bombay, I. 337–344.
Statement of Surgeon General Harvey's inquiry into the statistics relating to inoculations among, 26,435–42.

Karachi Khojas:

Census of Panjabhai Khojas, showing occupation, &c. in Karachi, accurate, 11,718–24, 11,734.
Gross mortality among Panjabhai Khojas at Karachi from October 1898, to January 1899, 11,780.
Gross mortality among Panjabhai Khojas in period before plague at Karachi, 11,728.

KHOJA COMMUNITY—*cont.*

Mortality among Panjabhai Khojas at Karachi during plague period from causes other than plague, 11,740.
Mr. Kaka's report on inoculation among the Khojas and other persons at Karachi, II. 423–45
Mr. Kaka's statistics checked by special house to house inquiries by Khoja headmen, 13,233.
Mr. Kaka's statistics of attacks and deaths derived from comparison of nominal rolls of casualties and inoculates, 13,227–39.
No explanation of difference between death-rate of inoculated and uninoculated children among Panjabhai Khojas, Karachi, 11,747–54.
Plague mortality among Panjabhai Khojas at Karachi, 11,735.
Possible that errors made in classifying dead persons as inoculated or uninoculated, 11,752–4.
Possible that inoculated persons resist disease better than uninoculated, 11,746.
Results of inoculation among Pirai Khojas, 11,772–6.
Verification of cause of death by corpse inspection not always made, 13,259.

See Karachi.

KIDNEYS:

Clinical Features of Plague:

Albumenuria, 10,422, 12,409, 15,300.
Hæmaturia, 15,307.

Discovery of Bacillus of Plague in:

Found post-mortem in kidney, I. 370.

Post mortem Appearances:

Of kidneys, 1421.
Only in two cases of post-mortem kidneys found to be affected, 9622.
Sometimes petechiæ on the capsule of the kidneys in bubonic plague, 10,421.

KILN BURNING:

Adoption of:

Hyderabad State, introduced by Mr. Stevens, all native floors to be treated with it, in, I. 443.
Hyderabad State: Kiln burning adopted to exclusion of other measures, 5443-9, 5846.
Thana: Used in, 19,673.
Umreth: Golas quarters disinfected by kiln burning, 14,037.

Attitude towards:

Approved by all village officers and by villagers themselves, I. 443.
Kiln method employed at Hyderabad popular, 5159.

Danger of:

Apt to give infection to persons employed in digging up the floors, 24,022.
Kiln burning a dangerous process on account of the carelessness of the coolies, 22,727.
Previous lime-washing important to lay dust and secure completeness, I. 456.

Efficacy of:

Effect of kiln method on mortality in Hyderabad villages, I. 459.
Fresh cases of plague in village disinfected by kiln burning process, 22,716–32.
In the Nizam's territory, used with great success, 5449.
No bacillus found after its use, I. 442.
No cases returned after floors have been dug up and burned, 5449, 5851.
No second outbreak after use of kiln method, 5471.
Sufficient without further disinfectants, 5470.

Expense:

Great cheapness an advantage of kiln burning, 5059.
Kiln system cheaper than disinfection with perchloride of mercury, 19,677.

KILN BURNING—*cont.*

Method of:

Floor should be allowed to smoulder for a week and when removed can be used as manure, I. 456.
Full description of, 5469–72, I. 456.
Plan of kiln, I. 457.

Necessity of:

All floors should be burned throughout India, I. 447.
Advantages of kiln burning compared with chemical disinfection, 5159, 19,675.

KIRKI:

Inoculation with Mr. Haffkine's prophylactic in:

Doses used at Kirki, 184–190.
Epidemic from July to September 1897, 21,206, 21,222.
Five hundred and sixty-one deaths during epidemic, 21,314.
Inoculations performed at Kirki, 68.
People left the town during the period of the inoculation, 160.
Records of inoculations at Kirki valueless, 21,230–5.
Special report made for Mr. Haffkine's report, probably not based on the records said to be valueless, 21,975–81.
Statistics personally checked by Mr. Haffkine, 26,531–4.
Statistics of plague and inoculation in Kirki, 26,535.

KUMAUN:

See Bombay, *Introduction of plague into.*
,, Mahamari and Sanjar.

LABORATORIES:

See Bacteriological laboratories.

LACTIC ACID:

Results of experiments, II. 7.

LANAULI:

Inoculation with Mr. Haffkine's prophylactic in:

Doses used at Lanauli 184–190.
Effects of inoculation at Lanauli striking, inoculated part of town having no plague and the other part suffering, 18,430–3.
Inoculations performed at Lanauli in July, 1897, 60–65.
Lanauli investigation sheets, 161.
People left Lanauli during inoculation period, 160.
Statistics of plague and inoculation in Lanauli, 26,535.

LATRINES:

Arrangements for and attitude towards:

Anand Camp: Latrine arrangements, 14,144.
Bangalore: Privies generally in cow yard, 4912.
Bombay: The provisions of the new Act with regard to privies will be difficult to carry out, 872.
Dharwar: Five public latrines and two trenches capable of holding 20 seats, 2306, 2327.
Dharwar: Quite inadequate for the large population, 2313.
Hinganghat: Public latrines outside the town; fairly well-to-do people have privies in their back yard, 6262–5.
Indian habit of making a *latrine* of the roads ought and can be stopped, 24,194.
Karachi: Voluntary camps: Narrow trench dry earth system of, with compartments used, 11,884.
Mahajans have a great dislike to the use of latrines, 13,351.
Mandvi: Latrine arrangements extremely bad at beginning of epidemic, 13,351.
Sind: Common custom to use the top of the houses as w.c., 11,088.
Surat: Several thousand pit privies closed with earth, and open privies constructed over them, 24,459.

LATRINES—*cont.*

Latrines and Plague:

Disinfection of public latrines is often shirked owing to caste and prejudice, II. 13*a*
Latrines in need of efficient disinfection, II. 13.
One compound infected in which only means of communication of infection was the latrine, 11,958.

LEECHES:

Application of leeches to a case of bubo, 9253.
Characteristic growth from leeches which had been applied to plague buboes, 22,286.
Possible infection of villages through leeches used in the plague-infected camps for other diseases, 22,287.

LEPERS:

Only one case in Bombay among lepers, 917.

LESIONS:

Discovery of Bacillus in:

Plague bacillus found in small lesion near bubo; four cases, I. 374, 1393.

Frequency of:

Abrasions: Plague patients generally have many abrasions on the skin, ring-worm, scabies, &c., 1393.
Natives commonly have scabs and eczema, 18,506.
Natives suffer much from skin diseases, 536.

See Habits of people.
,, Infection, modes of.

LIABILITY TO PLAGUE: CIRCUMSTANCES INFLUENCING INDIVIDUAL:

Healthy and robust people suffer from the most violent form, and die in greater proportion than those of less sthenic constitution, III. 281.

See Age.
,, Caste.
,, Habits.
,, Occupation.
,, Race.
,, Religion.
,, Sex.

LIFE OF BACILLUS OF PLAGUE:

See Bacteriological characteristics of bacillus of plague.
,, Period for which plague bacillus can survive.

LIGHT:

See Air and light.
,, Sun.

LIME:,

Attitude towards Disinfection by Quicklime:

Banga, whitewashing approved of by people in, 10,306.
Poona: Great opposition to the floors being spread over with quicklime, 21,590.

Chloride of Lime:

Chloride of lime, best in powder, 1226.
Results of experiments with chloride of, II. 9.

Efficacy of Quicklime as a Disinfectant:

Combines with and neutralises many of the more commonly used disinfectants.
Doubtful whether whitewashing is a sufficient precaution against plague, II. 6.
Lime-washing for disinfecting purposes of very little use in India, 8689.
Lime-washing apparently ineffective as disinfecting method, 1214.
Lime-washing alone insufficient, 10,972.
Result of tests with quicklime, II. 6.

Use of Quicklime as Disinfectant:

Ahmedabad: Lime-washing used as disinfectant, 13,923.
Baroda: Disinfection confined to lime-washing at commencement of epidemic, 14,590.

LIME—*cont.*

Baroda: Uninfected houses cleaned and whitewashed in, as disinfecting precaution, 14,631.
Bombay: Umarkhadi Jail: Disinfection with boiling quicklime and carbolic dilute failed to prevent succession of cases in the particular place disinfected, 20,344.
Danger in digging up floor minimised by whitewashing it, 5554.
Dharwar: No plague after whitewashing, &c. of dug-up floors, 23,778.
Guntakal: Lime applied to roof and walls as disinfectant in, 5099, 5100.
Kalindri: Resorted to as disinfectant, 9894.
Mandvi: Quicklime and sulphur used as disinfectants considered quite as effective as more expensive agents, 13,458.
Panjab: Whitewashing done with unslaked lime 30 per cent. strength, to disinfect, 10,034.
Poona: Use of lime alone as disinfectant found valueless, 10,972.
Rohri: Lime resorted to, to disinfect, 12,029.

See Perchloride of mercury.

LIVER:

Clinical Features of Plague:

Liver not enlarged, 12,412.
Liver in bubonic plague somewhat large and congested, 10,421.

Discovery of Bacillus of Plague in:

Found in liver of plague corpses, 7189.
Found post-mortem in liver, I. 370.

Post-mortem Appearances:

Of liver in septicæmic case, I. 439.
Of liver, I. 367.

LOCALITY:

See Infection by locality.

LUNG:

Clinical Features of Plague:

Acute pneumonia a complication of plague, 10,212.
Bronchial pneumonia, 15,876.
Bronchial symptoms in plague cases very common, 26,251.
Frequency of lung symptoms varies in an epidemic, such symptoms being at one time common and again absent, 21,042.
Hypostatic congestion of the lungs a common symptom, 20,821.
Lung symptoms a bad prognosis, 19,078.
Lung symptoms generally late, 329.
Pneumonic plague: Œdema of lungs a common symptom, generally noticed on third day of illness, 20,823.
Pneumonic plague: Hæmorrhage from the lungs without the characteristic signs of pneumonia, 12,897.
Pneumonic plague: The lungs are acutely inflamed; the pneumonia is of lobular type, 10,431.
Pneumonic plague: Secondary lung symptoms appear on the fifth or sixth day, 25,321.
Pneumonic plague: Secondary pneumonia, 20,827.
Septicæmic plague: Nearly every case of septicæmic plague complicated with some pneumonic symptoms, 27,187.

Discovery of Bacillus of Plague in:

Bronchi, recovered after death from, with other bacilli, from lungs in pure cultures, 6916.
In pneumonic plague cases the bacilli occur in large masses in the consolidated portion of the lung, 6915.
Plague corpses, found in lungs of, 7189.
Post-mortem in pneumonic cases found in lungs, I. 370.

Means of Infection, A:

Infection generally through inhalation, 22,360.
Infection not external, but pulmonary, 222, 230, 332–9.

LUNG—*cont.*

Infection possibly by lungs, 7076.
Inhalation, by air, produces pneumonic plague, I. 351, I. 369.

Post-mortem Appearances:

Appearance of the respiratory system, I. 368.
In two cases white hepatization of the lungs resembling the wedged-shaped masses of secondary cancer, 6916.
Pneumonic plague; Appearance of lungs in pneumonic form, 6913–6, I. 368.
Pneumonic plague: Lobar consolidation observed in every case of pneumonic plague, 9549.
Pneumonic plague: Lungs internally engorged in pneumonic cases many patches of pneumonia, 1421.
Septicæmic plague: Appearance of lungs in septicæmic cases, I. 439.
Septicæmic plague: No pathological changes observed in the lungs of persons having died of the septicæmic variety of plague, 9569.

Prognosis:

Lung symptoms a bad prognosis, 19,078.

LUSTIG'S SERUM.

Animals:

Has curative effect on animals, I. 348.
Note on the effect of vaccination in animals, I. App. 6.
Protects animals absolutely against infection of plague, I. 347.
Series of experiments on rats to test protective power, 26,218.
Statement of laboratory experiments on animals with generally unfavourable results, III. 325–6, III. 332–3, III. 336, III. 345.
Test of the serum by Dr. Galeotti on animals with favourable results, III. 325–6.
White mice die of shock soon after injection with serum, 26,058.

Clinical Symptoms:

Clinical charts of 53 cases treated in the Arthur Road Hospital, Bombay, Vol. III., App. LXIII.
Convalescence rapid, and less suppuration of the buboes, 20,954.
Lung symptoms not immediately effected, 26,034.
No post-mortem examinations made after, 405.
Pulse effected in 4 or 5 hours, 26,028.
Reports by Dr. Choksy and Capt. Childe on cases treated in the Arthur Road Hospital, Bombay, Vol. III., App. LXII.
Temperature and size of bubo reduced; serum has bactericidal effect, 402.

Dose: Dose from 30 to 120 c.c., 354.

Efficacy:

Bombay, Arthur Road Hospital, and Poona, results, 352.
Bombay, Arthur Road Hospital: In March 1898, and until 30 moribund cases had been treated, all cases treated; after that moribund and convalescent admissions not treated, 20,945–50.
Bombay, Arthur Road Hospital: Statement of results from March to October 1898, 20,952.
Bombay, Arthur Road Hospital: Very good results of Lustig's serum in 1897, 20,934.
Harmless in man, I. 348.
Improvement in cases which died of other complaints, and some cases which died 15 or 20 days after of uræmia, 402.
Memorandum on the efficacy of the serum, III. 323.
Parel Hospital, no effect on plague, 7,233.
Poona: Results of, 352, 409.
Recovery after injection of Lustig's serum in three cases in which the bacilli had been found in the blood, 17,704–5.
Saving of life about 23 per cent., 353.
Two cases treated with Lustig's serum recovered, 19,114.
Typical plague case recovered after injection of Lustig's serum, 17,810.

LUSTIG'S SERUM—*cont.*

Nature and Preparation:

Has chemical character of nucleo-proteids, I. 347.
How obtained from horses, 355–70, 398–400, 408–9.
Method of preparation and character of, I. 347.
Notes on the preparation of the samples tested by the Commission, 26,210, 26,213.
Not an anti-toxin, mainly a bactericidal serum, 25,980.
Serum might be improved by giving larger dose of toxin to horses, 407.
Table of comparison of the toxicity of Galeotti's serum, with the toxicity of normal horse serum, III. 336.
Vaccination method slow, I. 347.

LYSOL:

Action of lysol on bubonic microbe, II. 5.

MAHAMARI AND SANJAR:

Arranged under the following subheads:

Air and Mahamari.
Bodies of Persons dead of, Disposal of.
Buboes in Mahamari.
Character and Clinical Symptoms of.
Climatic Conditions and Mahamari.
Description of Kumaun and Garhwal.
Difference between Mahamari and Sanjar.
Endemicity of Mahamari.
Enquiries regarding Mahamari.
Epidemic Diseases in Kumaun and Garhwal other than Mahamari and Sanjar.
Food and Grain and Mahamari.
Habits of the People of Kumaun and Garhwal.
Immunity of particular Places and Persons from Mahamari.
Importation of Mahamari into Kumaun and Garhwal.
Incubation Period of Mahamari.
India, Communication of Mahamari to, from Kumaun and Garhwal.
Locality and Mahamari.
Measures, Precautions, and Rules relating to Mahamari in Kumaun and Garhwal.
Mild Forms of Mahamari and Sanjar.
Monkeys and Mahamari.
Mortality from Mahamari and Sanjar.
Native Names for Mahamari.
Opinions regarding the Nature and Character of Mahamari and Sanjar.
Outbreaks of, History and Continuity of.
Personal Communication of Mahamari.
Pneumonia and Mahamari.
Post-mortem appearances of Mahamari.
Rats and Mahamari.
Recrudescences of Mahamari.
Sanitary Conditions and Mahamari.
Snakes and Mahamari.
Soil and Mahamari.

Air and Mahamari:

The fact that it is not generally prevalent shows that the disease is not carried by the air, App. XXV., sect. 246.

Bodies of Persons dead of, Disposal of:

Corpse eaten by jackals, 26,603.
Mahamari dead not buried, but left to be pulled about and eaten by jackals, II. 338.
Remarks on the scattering of the germs of the disease owing to the non-burial of the bodies of those who have died of mahamari, App. XXV., sect. 251.

Buboes in Mahamari:

Buboes not noticed in those who died quickly at the onset of the epidemic in Bintola, and noticed only at a later stage of the outbreak, II. 338.
First three cases of the 1897 outbreak in Semi had no buboes, II. 370 (1).
In 1897, in Sankari, buboes appeared in one case only out of five, II. 371 (3).
No swellings in large number of cases that occurred in Bhandargaon, App. XXV., sect. 182.

Character and Clinical Symptoms of:

Delirium and wandering about, 26,587
In 1834 symptoms, onset sudden, fever, thirst, desire to eat bitter things, buboes followed by choleraic symptoms, App. XXV., sect. 95.

MAHAMARI AND SANJAR—*cont.*

In 1849 symptoms noted, fever, contagiousness, swellings, with crisis on the third day, App. XXV., sect. 96.
Instances of plague with vomiting, II. 364 (19).
No petechiæ noticed in 1876–77, App. XXV., sect. 240.
Summary of clinical symptoms observed by Dr. Planck in 1876–77, App. XXV., sect. 242.
Summary of the symptoms of mahamari (Douglas and Walton), II. 369 (6c).
Surkali, 1893, symptoms described, II. 368.
Suffusion of conjunctivæ, 26,586.
Symptoms high temperature, quick pulse, early death, 26,585.

Climatic Conditions and Mahamari:

Disappears in the hot weather, II. 363 (6).
Mahamari breaks out in the cold weather in damp places, when the people crowd together, 8827, 8995.
Mahamari occurs in hot weather, cold weather, snow, and rains, 6166.
Rainfall, soil, temperature, and elevation vary greatly in different parts of the affected tract, II. 366.

Description of Kumaun and Garhwal:

Description of Garhwal and Kumaun, II. 366.

Difference between Mahamari and Sanjar:

Colonel Thompson thinks that both mahamari and sanjar are the same disease, sanjar being a less infectious and less fatal; one may merge into the other, 8825–6, 8966.
Decline of mahamari to sanjar not noted as mahamari when discovered is stamped out, 8996–7.
Early delirium, fever, and contagiousness noticed in both sanjar and mahamari, 8953.
Instance of epidemic of mahamari and sanjar, side by side, 8894–5.
Mahamari same as plague in the plains, sanjar with no glandular swellings, 8823, 8901, 8960–1.
Not infrequent for disease never to pass beyond the sanjar state, 8967–8.
People consider mahamari and sanjar the same disease, 8824.
People differentiate between sanjar and mahamari by the appearance of buboes, 26,604.
People do not think that sanjar develops into mahamari, 26,604–5, 26,631–4.
Rats die before mahamari but not before sanjar, 8827, 8896–9.
Sanjar, a severe fever, only recognised as such when its infectiousness becomes apparent, 8953, 8827.
Sanjar has all the symptoms of plague, except buboes, and is milder than ordinary mild plague, 8902, 8946, 8827.
There may be half a dozen cases of sanjar before a man dies with buboes and mahamari is recognised, 8953.

Endemicity of Mahamari:

Endemic in Garhwal, probably for centuries, 26,575.
Evidence in Kumaun and Garhwal, 1558.
Familiarity with, and general knowledge of, the Native names for the disease a proof that it has probably been known in Kumaun for a long time, and probably before 1823, App. XXV., sect, 245.
Mahamari occurs in all parts of Kumaun, 6157.
People spoke of mahamari as a familiar thing, 26,615.

Enquiries regarding Mahamari:

Enquiry in 1899 by Lieutenant Walton, I.M.S., and Lieutenant Douglas, I.M.S., under orders of Indian Plague Commission, II. 365–373.
In 1850, Dr. Renny made a report after special investigation and seeing cases, App. XXV., sect. 98.
In 1851, Dr. Pearson and Assistant Surgeon Mukerji investigated the disease, App. XXV., sect. 101.
In 1852, Dr. Pearson and Assistant Surgeon Mukerji made another investigation, App. XXV., sect. 102.
In 1852–53 an investigation was made by Drs. Pearson and Francis, App. XXV., sect. 103.

MAHAMARI AND SANJAR—*cont.*

In 1877, an enquiry was made by Dr. Planck, who visited 40 mahamari villages, and submitted a full report on them, II. 337–364.
No bacteriological facts ascertained up to the present, 8904, II. 365.

Epidemic Diseases in Kumaun and Garhwal other than Mahamari and Sanjar:

Besides mahamari and sanjar there are no special epidemic diseases in Kumaun and Garhwal, 368 (6b).

Food and Grain and Mahamari:

Grain not the cause of infection, App. XXV., sect. 254.
Grain the cause of the disease because rats, mice, and snakes die, II. 362 (4), II. 363 (11).
Mahamari imported into Surkali by grain dealers II. 368.
No connexion between the disease and food grains, as people who take their grain with them into the jungles remain free after evacuating their villages, 8831.
Not due to grain, 26,588.
People believe that food will carry the infection; in one case the only person attacked among evacuated villagers was a boy who went back to the infected village and got some coarse sugar from it, 8832.
Possible cases of infection by grain in 1877, App. XXV., sects. 120, 130, 218.
Possible cases of infection through ghi and grain in 1877, App. XXV., sects. 159, 165.
Possible case of infection in 1877 through ghi, App. XXV., sect. 233.

Habits of the People of Kumaun and Garhwal:

People dirty and never wash, 6108–9.
People do not wear shoes, 26,573.
People never wash themselves, thinking that dirt is a preventive of mahamari, and they also have cuts on their feet frequently, 8832.

Immunity of particular Places and Persons from Mahamari:

Dasauli: Though surrounded by affected tracts, has remained immune, except for a small outbreak in two villages in 1864, II. 366.
Kidarnath: Pilgrims have never had mahamari, II, 366.
Pilgrims immune, II. 363 (15).
Two tracts close by two tracts that suffered extremely escaped, II. 364 (18).
Villagers remain free near certain villages in which the disease recurs, 8827.

Importation of Mahamari into Kumaun and Garhwal:

Before coming over into Garhwal, Thibetans make special enquiries about the existence of mahamari, and take precautions against it, II. 369 (d).
Importation improbable, 26,617–8.
No mahamari heard of in Thibet, II. 369 (d).
Possible importation from Yunnan by communication with countries north of the Himalayas, 26,574.
Suggested existence in Nepal and importation thence, but not known in parts of Garhwal near Nepal, II. 369 (d).
Villages at foot of Mana and Niti passes have never had mahamari, II. 366.
Villages on trade route to and near Thibet have no mahamari, II. 369 (d).

Incubation Period of Mahamari:

Incubation period less than 24 hours, II 362 (3).
Incubation short in both mahamari and sanjar, 8827.

India, Communication of Mahamari to, from Kumaun and Garhwal:

About 50 years ago the disease was introduced from the Hills into Bijnaur and Moradabad, 8836.
Communications are bad, the trade small, and the disease is usually found to occur several days' march from the plains, 8834.
Infection not imported from Kumaun to Hardwar, 8765, 6185.
Inter-communication with India slow and difficult, II. 370.

MAHAMARI AND SANJAR—*cont.*

Introduction from Okhimath into Bombay very improbable, 8836.
Mahamari was once imported from the Hills to the plains, 6181–2.
The only danger from pilgrims and from the Panda Brahmans of the hills who pass the winter in India, II. 370.

See also Introduction of Plague into Bombay.

Locality and Mahamari:

Cause of disease lies in the houses, as a child or woman generally suffered first, 26,575, II. 360 (250).
Chuni, 1895, a case was attacked in the jungle, after the people had left the village, II. 371 (4).
Contracted by visits to mahamari houses, II. 369 (6c).
Disease contracted by return to houses vacated, 26,576.
In Balt all remained well until a fall of snow drove the people, after evacuation, back to their houses, when the disease re-appeared, II. 339.
Infection kept alive by visits to infected houses, App. XXV., sect. 263.
Infection most potent in the house in which a case has occurred, less so in the open air, App. XXV., sect. 261.
In many cases the disease is restricted to localities or houses, App. XXV., sect. 247.
Semi, 1897, all five cases were of people belonging to one house, II. 371 (3).
Suini outbreak, 1893, two cases directly due to return to infected houses, II. 368.

Measures, Precautions, and Rules relating to Mahamari in Kumaun and Garhwal:

Concealment for any long time impossible, and villagers take steps to guard themselves, 8834.
Most important measure is improved sanitation, during periods of attention to sanitation, outbreaks were few, II. 361 (256).
No person of an infected village dares to pass into an uninfected village, II. 339; II. 341.
People favour the burning of mahamari houses, 26,576.
Rules prescribed by Government for dealing with mahamari, 8836–41; II. 338 (104–5); II. 377.
Villagers evacuate their villages on the death of rats, 8839–40.

Mild Forms of Mahamari and Sanjar:

Dr. Planck knows no epidemic with low mortality, 26,589.
Mild cases few, 26,581.
Neither sanjar nor mahamari patients can walk about, 8962–5.
No evidence of existence of less fatal and atypical forms, II. 369 (6c).
Sanjar milder than ordinary mild plague, 8827, 8902, 8946.

Monkeys and Mahamari:

Chuni, 1895, monkeys swarm, but none sickened, 371 (4).

Mortality from Mahamari and Sanjar:

Case mortality very high, II. 369 (6c).
Extremely fatal: in one instance two houses affected, and all inmates died, in one house five, and in the other six, 6193.
In 1834, fatal termination in 3 to 4 days, App. XXV., sect. 95.
In 1850, Dr. Renny found that the disease was usually fatal in from 3 to 4 days, II. 336.
In 1876–77, in 291 cases, case mortality 95 per cent., App. XXV., sect. 244.
Mortality in an outbreak of mahamari 75 per cent., 8903.
Mortality in an outbreak of sanjar 20 per cent., 8900, 8962.
Sanjar fatal, as a rule, in a week or ten days, 8948–9.

Native Names for Mahamari:

Disease called mahamari, golarog, and phutkiarog, II. 368 (6).
Name sanjar includes relapsing fever, II. 368 (6).
Native names for plague, 26,588.
Mahamari is called by the people golarog, 8944.

MAHAMARI AND SANJAR—*cont.*

Sanjar means an epidemic in which the mortality is slight, II. 368 (6).
Sanjar means the infectious disease, 8943.

Opinions regarding the Nature and Character of Mahamari and Sanjar :

An epidemic of sanjar found to be relapsing fever, the diagnosis being confirmed by an examination of the blood, II. 368 (6).
Dr. Pearson and Assistant Surgeon Mukerji, in 1851, thought that mahamari was typhus fever, App. XXV., sect. 101.
In 1850, Dr. Renny thought the disease was not plague, but malignant typhus with buboes, the appearance of which was an unfavourable sign, II. 336.
In 1852, Dr. Pearson and Assistant Surgeon Mukerji came to the opinion that mahamari was plague, App. XXV., sect. 102.
In 1852–53, Drs. Pearson and Francis reported mahamari to be plague, App. XXV., sect. 103.
Mahamari is true plague (Planck), 26,573.
No skin eruption in sanjar, which has been wrongly called typhus, 8957–9.
Sanjar is ordinary infective fever, 26,602.
Sanjar the same thing as plague, but less fatal, App. XXV., sect. 253.
Summary of previous opinions regarding nature of mahamari. II. 368 (5).
Symptoms differentiate mahamari from typhoid, II. 362 (1).
Walton and Douglas think mahamari identical with plague, II. 369 (6c).

Outbreaks of, History and Continuity of :

Between 1870 and 1897 outbreaks not traced only in 1872, 1880, 1881, 1889, and 1890, II. 370.
Case at Okhimat in August 1896, 10 marches from the plains, and after the Bombay plague began ; no case in 1897 or 1898, 8842, 8835.
Disease said to have existed for 30 years before an outbreak which occurred in 1849; more prominent outbreaks before that date enumerated, App. XXV., sect. 97.
History of the disease in 40 villages in 1876–77, II. 337–53.
In recent times restricted outbreaks have been noted every year, 8836.
Mahamari has occurred frequently since 1832, 6167.
Mahamari noticed in 1834, and then said to have originated in 1823 on account of the anger of the gods at certain mistakes committed in ritual, App. XXV., sect. 95.
Mention of all outbreaks not made in official reports; limited outbreaks easily overlooked, II. 369 (e).
Most recent outbreak in Phali, Semi, Ukhimath, and Sarkari in 1896–97, II. 365.
No mahamari in 1897 or 1898, 8842.
Outbreak at Okhimath on 26th August 1896, 8835.
Outbreaks confined to small and isolated areas, II. 370.
Outbreaks more frequent than would appear from the records, II. 369 (d).
Supervision over the tract not sufficient to allow it to be said whether or not there are long periods without outbreaks, 6187.

Personal Communication of Mahamari :

Almost certain death to sleep in same room as a patient, II. 363.
Instances in which the disease could be proved in 1876–77 to have spread by personal communication summarised by Dr. Planck, App. XXV., 248.

Pneumonia and Mahamari :

Pneumonic plague not heard of in the Hills, 8833, 8955.

Post-mortem appearances of Mahamari :

Post-mortem appearances recorded in 1852–53, App. XXV., sect. 103.

Rats and Mahamari :

Bintola, 1876–77, many rats die, II. 339, sect. 118.
Chuni, 1895, dead rats seen, II., 371 (4).
Dead and dying rats a feature of the outbreaks inquired into by Walton and Douglas, II. 369 (6c).

MAHAMARI AND SANJAR—*cont.*

Dead rats observed in 1876, 26,607.
Death of rats observed in 1876–7, App. XXV., sects. 159, 164, 169, 175, 190 ; II. 362 (4).
Death of rats occurs in recrudescences, not when the disease is imported, App. XXV., sect. 259.
Death of rats precedes recrudescence, but not importation, II. 363 (9).
Grey rats die before a recrudescence, but not before an importation, 26,578.
In 1834 mortality among rats preceded outbreak, App. XXV., sect. 95.
Mortality among rats occurs, 6171–2.
Rats died in Phali in 1896, II. 367, II. 370 (2).
Rats said to die of mahamari, 8827.
Summary of histories of deaths of rats in 1876–77, App. XXV., sects. 254, 259.
Surkali, 1893, dead rats seen, II. 368.

Recrudescences of Mahamari :

Chuni, attacked 1895, has had two outbreaks, II. 371 (4).
Disease may break out again after several years; certain tracts more liable than others, 8827.
Phali, where disease reappeared in 1896, has had two outbreaks, II. 367.
Possible case of recrudescence in the same house after 16 years, App. XXV., sect. 179.
Sankari, infected 1897, has had two outbreaks, II. 370 (1).
Semi, infected in 1897, has had three outbreaks, II. 367.
Surkali, infected 1893, has had two outbreaks II. 368.
Tendency noticed of disease to start in houses of great age, App. XXV., sect. 261.

Sanitary Conditions and Mahamari :

Halting places on pilgrim routes more foul and dirty than the ordinary houses of the people, but the pilgrim routes have never had mahamari, II. 366.
In 1852–53, Drs. Pearson and Francis thought mahamari to be due to insanitary conditions, and steps were taken to improve the sanitation of the houses in the hills, II. 336.
Insanitary condition of houses, 26,611, 26,631 II. 338, II. 346, II. 363, II. 366.
Insanitary conditions the cause of the germs becoming active again when they get into the bodies of debilitated persons, App. XXV., sect. 252.

Snakes and Mahamari :

Death of snakes from mahamari noticed in 1876–77, App. XXV., sect. 190.
Question whether snakes die of mahamari, App. XXV., sect. 254.
Snakes said to die of mahamari, 8827.

Soil and Mahamari :

People believe the infection to lie in the soil, 8832.

MAHARS :

Mahars and other outcasts escaped infection in infected areas even when not evacuated, 24,051.
Mahars live an outdoor life, 24,054–7.
Plague spread by the Mahars. 15,337.

MANGS :

Mangs not much subject to plague ; impure people, 5478, 5556.
Mangs remained comparatively free, 24,004.

MAPS AND CHARTS :

Clinical Charts of Plague Cases :

Clinical chart of Atit Bawa (plague patient, Cutch Mandvi), II. 471.
Clinical chart of Chinaman landed at Bombay with plague from s.s. "Bormida" from Hong Kong, III. 303.
Clinical chart of Ibrar Hussain (plague patient, Jawalapur), II. 387.
Clinical charts of plague cases, I. 385–390
Clinical charts of 13 plague cases, Arthur Road Hospital, Bombay, III. 529–545.
Clinical charts of 2 cases of plague septicæmia, III. 407–9.
Sphygmographic tracings of plague patients, Arthur Road Hospital, Bombay, III. 547.

MAPS AND CHARTS—*cont.*

Clinical Charts of Plague after Inoculation with Haffkine's Plague Prophylactic:

Charts attached to Captain Leumann's Report on inoculation at Hubli, I. 411–415.

Kotri, Sind: Plan of, II. 447.
Kotri, Sind: Plan of, and outskirts of the town, II. 455.
Lidhar Kalan: Plan of, Panjab, II. 417.

MAPS AND CHARTS—*cont.*

Map illustrating notes on traffic between Bombay and Madagascar, III. 587.
Panjab: Maps of the, II. 391–401.
Surat: Plan of Mahidharpur ward, II. 525.

Photo-micrographs:

Photo-micrographs of cultures made in connection with the suspected plague in Calcutta in 1896, III. 369–76.
Photo-micrographs of cultures of plague bacilli, and slides prepared in the Hyderabad State Laboratory, I. 443–8.

Plan of Kiln:

Plan of kiln used for kiln burning floors, I. 457

MARWARIS.

See Banniahs and Traders.
,, Habits of the people affecting liability to plague.

MATTING:

Discovery of Bacillus of Plague in:

Once found in soiled matting which had been used as bedding, 25,394.

MEASURES, PLAGUE:

Adoption and Organisation of:

Bangalore: Measures adopted in, 3480.
Baroda: Isolation of the sick and segregation of the contacts did not arrest the progress of the disease, 14,604.
Bassein: No thorough measures taken during either of the epidemics, 14,465.
Belgaum: Disinfection of houses and burial parties the only plague measures employed, 22,807.
Belgaum: Plague measures in the Bhangi quarter, 2076–103.
Bombay: Plague measures adopted in Bombay from March 1897 to May 1898, 20,446.
Bombay: Committee appointed in September 1896 to devise plague measures, 26,638.
Bombay: Harshness in the carrying out of the restrictive measures, 17,863.
Bombay: Large sums spent by Government to fight the plague, 17,244.
Bombay: Unsystematically carried out, 10,959.
Broach: Organisation of plague measures, 15,484.
Cutch Mandvi: Plague measures in the early months of 1897, 13,377–83.
Hyderabad State: Plague measures at, I. 18, 6–90, I. 194–201.
Karachi: Plague measures at present in force, 13,202–15.
Karachi: Measures taken by the Plague Committee, 11,158.
Karachi: Manora remained free from plague during the epidemic of 1898 owing to the energy of the plague superintendent, 12,273.
Karad: Plague measures carried out in an effective way, 21,064.
Karad: Evacuation impossible on account of the rain. Segregation of contacts and disinfection of the houses the only measures adopted, 21,077.
Khandraoni: Instructions from the Maharaja for stringent plague measures, 9638.
Kirki: Great confusion in the plague measures, 21,213–4.
Malegaon: Description of plague measures, 18,070.
Malegaon: Successful results due to the efficiency of the plague measures, 13,845.
Palanpur: Measures taken on the reoccupation of the town by the people, 13,097.
Palanpur: Plague measures, 13,072.
Panjab: Segregation of patients and their friends, evacuation of the whole village, and disinfection of the whole place were measures adopted, 10,450.
Poona cantonment: Organisation of measures, 21,259.
Poona: No evacuation during first epidemic, but rigorous plague measures, 21,690.
Poona: System of plague organisation allowed of each case to be treated as it arose, 21,766.

MEASURES, PLAGUE—*cont.*

Sind: Successful plague measures, 18,385–6.
Surat: Very rigid during first epidemic, 24,411.
Surat: Early plague measures in the town, 15,572.
Surat: No systematic methods at beginning of epidemic, 15,578.
Surat: Plague measures at, 2032–66.

Co-operation of the People and Assistance in; Necessity for and Relaxation in Measures to secure:

Bangalore: In favour of home segregation, plague measures abandoned at, 3293.
Bangalore: Popular feeling now improving, 2604.
Belgaum: The fear of Government measures being removed, people willingly notify plague, 23,138.
Bellary district: No difficulty with regard to plague measures, 4941.
Bombay: Conciliatory methods in Byculla section, good results from, 17,945.
Bombay: Plague measures less stringent in third than in first epidemic, 26,561.
Broach: Most satisfactory results in dealing with mill hands by getting plague measures voluntarily carried out, 15,483.
Calcutta: Bombay measures had to be modified at, I. 468.
Chak Bilga: People took the initiative of precautionary measures, 10,303.
Co-operation of the natives in Government plague measures most essential, 22,558.
Co-operation of the people the most effective factor in combating epidemics, 26,558.
Daman: People more readily induced to evacuation and isolation during the last epidemic, 16,493.
Forcible system at Bangalore extremely expensive, 25,089.
Force a good thing for stopping plague, but bad in other respects, 22,054.
Hardwar: No complaints against Government measures, 9322.
Hardwar: Satisfaction of the people with plague measures, 9307.
Hyderabad: After first scare, people fully entered into the spirit of the plague measures, 18,132.
Impossible to control epidemic if the population is antagonistic, 21,318.
Improvement in the feelings of the people with regard to plague measures, 14,762.
Influence of leading natives a great help, 24,566.
Initiative taken by the villagers the result of experience in former outbreak, 22,215.
Kaira district: No trouble with the villagers, 14,065.
Karachi: People are helpful in assisting plague measures, except as regarding the burning of their clothes, to which they object, 11,379.
Karanja: Loyal assistance in plague measures from the people, 17,611.
Kumaun: The people in the hills themselves recognise the necessity of sanitary measures, 8838.
Leniency and kindness necessary in carrying out, 15,500.
Maximum of efficiency with the minimum of inconvenience to the people should be combined, 21,527.
Mysore: No force employed; measures left to the acceptance of the people with good results, 24,956.
Natives in villages being ignorant and excitable, the measures should be carried on through their headman, 25,172.
Nothing can be done unless the people be got to work with the Government, 22,987.
People fairly convinced now of the benefits, 22,169.
Poona: Modification of plague measures restored the confidence of the people, 21,702.
Poona: Plague measures relaxed during second outbreak, as the help of the inhabitants could be relied on, 21,694.
Poona: Regular system introduced for hearing complaints, 10,968.

MEASURES, PLAGUE—*cont.*

Sholapur: People at first opposed measures, but after gaining experience cooperated, 22,996-001.
Spread of epidemic to neighbouring villages prevented by the natives themselves, who broke off all communication with the infected places, 9672.
Surat: No opposition, 26,656.
Sympathetic treatment a great factor in successfully dealing with the natives, 17,970, 26,656, 26,803.
Utility of preventive measures being recognised by the people a hopeful sign for the future, 10,305.

Essentials of Plague Measures (Disinfection, Early Information, Evacuation, Segregation, &c.):

Basis of the regulations issued in February, 1898, by the Government of India, III. 362.
Discretion should be allowed in the execution, 21,552.
Early information, evacuation, segregation, and inoculation important, 26,708.
Early information, of plague cases evacuation, and disinfection, the most important measures in dealing with plague, 16,967–71.
Evacuation, segregation, and disinfection valuable in the order named, 23,032.
Great license is allowed to officers according to local conditions, 26,655.
If plague discovered early, ordinary measures stamp out epidemic, 14,062.
Improvements in the condition of the people the fundamental reform necessary for limiting plague epidemics, 25,277.
In large places only possible methods are searching, paid informers and enlisting the co-operation of the inhabitants themselves, 10,963.
Inoculation combined with complete evacuation the ideal plague measures, 22,408.
Isolation, segregation, and evacuation most essential, 13,191.
Isolating the sick, isolating the contacts, and personal disinfection most necessary, 12,053–5.
Observation camps, disinfection stations, medical examination stations, medical surveillance, and immediate evacuation of infected places of equal importance, 24,352.
Panjab: Drastic plague measures necessary to prevent the plague spreading, 12,046.

Objections and Opposition to Plague Measures:

Ankleshwar: At the early stage of the epidemic the people did not co-operate in the sanitary measures, 14,238.
Backergunge: Caused trouble, people objecting to cremate their dead, 7419.
Bandra: Much opposition with regard to plague measures in, 18,931.
Banga: Dread of sanitary measures at first very great in the outlying districts, 10,265.
Bangalore: Opposition to plague measures; police officer stabbed, 2574.
Bombay: At appearance of plague in Bombay, measures directed to deal not only with men but also with rats, at first unpopular, 908.
Bombay: Difficulty in making people believe that the disease was dangerous, hence the opposition to measures, 908.
Bombay: Fear of the plague measures influenced the mental state of the people and the mortality, 17,694.
Bombay: Fort Northern a more difficult district to deal with than Kolaba, 18,489.
Bombay: Great excitement among the population when the compulsory measures were published on October 6th, III. 362.
Bombay: Irritation caused by the disturbance of trade, 1053.
Bombay: Plague measures interfered with by riots, March 1898, 16,955.
Bombay: No thorough measures allowed to be adopted, 10,946.
Calcutta: General belief that plague was designed by the British, I. 475.
Calcutta: Plague officers attacked, supposed inoculator murdered, I. 469.

MEASURES, PLAGUE—*cont.*

Calcutta: Police activity in discovering cases objected to, I. 469.
Daman: Portuguese Government unable to carry through plague measures on account of opposition, 15,983.
Experience slow in conquering fatalism, 222, 885.
Ghoti: Mamlatdar assaulted whilst inquiring into plague, 15,896.
Indian's point of view is that removal to hospital, segregation of contacts, and disinfection are objectionable measures, 16,232.
Karachi: Muhammadans in the Lyari quarter prosecuted for obstruction to the sanitary measures, and sentenced to one month rigorous imprisonment, 11,651.
Karachi: People strongly objected to the municipal government segregation camps, to quarantine, to the Malir camp, and to the military being employed on plague duty, 12,527.
Objection to plague measures so great that people will not report cases, 7824.
Risk of arousing opposition by measures affecting the habits and customs of the natives, 26,670.
Savali: Riots on account of the plague measures, 14,658.
Sinnar: Riots because of the plague measures, 13,792.
Surat: Great fear of plague measures, 15,864.

Precautionary Plague Measures:

Baluchistan: Precautions against entry of plague into, I. 286–7.
Bandra: Strict precautionary measures, 18,938.
Baroda: Organisation for precautionary plague measures in the villages, 13,128, 14,651.
Belgaum: Description of precautionary measures at, 23,128.
Belgaum: Regulations for keeping out plague in, 23,027.
Bijapur: Precautionary measures adopted in villages, 19,479–80.
Bombay City: Measures taken in anticipation of plague along line on which its progress expected, 916, 1255–8.
Broach: Precautionary measures kept plague out for a year and a half, 15,483.
Broach district: Tardy appearance of plague in the, owing to early precautionary measures, 14,336.
Calcutta: Instructions to householders at the beginning of the epidemic, I. 470–1.
Cutch Mandvi: Precautionary regulations issued by the Darbar, 13,344.
Gwalior State: Precautionary measures in the neighbourhood of Khandraoni, 9669.
Hyderabad Sind: Early information and proper measures prevented the disease for a long time from becoming local, 18,397.
Hyderabad State: Efficient plague measures at the first appearance of plague in the Nizam territory stop the spread of the disease at once, 5153, 5926–41, 25,291.
Kaira District: Details of precautionary measures, 14,014.
Karachi: Better precautionary measures in the second outbreak, 11,302.
Khandraoni: Precautionary measures, 9669.
Madras: Evidence on precautionary measures, I. 145–9.
N.W. Provinces: Precautionary measures adopted in, 8749–52, 8843, 8868–72, 9205–9.
Panjab: Precautionary measures to obtain information of infection of villages, 10,272.
Poona cantonments: Measures to prevent re-infection, III. 143–4.
Poona: Precautionary measures very lax at commencement of outbreak, 12,871.
Satara: Preventive measures, 22,520.
Shikarpur: People induced to use precautionary measures to avoid search parties, 18,288.
Umreth: Precautionary measures adopted to prevent the plague spreading to the villages, 14,052.

MEDICAL TREATMENT, EUROPEAN:

Attitude towards, in general:

Ahmedabad: 15 to 20 per cent. of the people treated by European and Native practitioners, 13,880.
Bombay: Before plague broke out only 10 per cent. of all dying attended by medical men, 1132–3.
Ninety-seven per cent. of the people in Surat never seen by doctors, 15,836.
Only 10 per cent. of the people resort to medical treatment, 21,856.
People of India do not appreciate medical treatment, and do not want it, 6635, 7789.
Small fraction only of Indian people have medical treatment, 7701, 7783–93, 8054.

Attitude towards, for Plague:

Bandra District: Treatment by Europeans objected to, 18,958.
Cutch Mandvi: The Jadejas would not admit a European doctor, but did not object to nurses, 13,531.
Hakims, at the end of the epidemic, treated patients according to European methods, 10,784.
Karachi: People in the voluntary camps at first objected to medical treatment from Europeans, but afterwards applied for it, 11,904.
Native States: People averse to inoculation, or any treatment at all, 9803–4.
Natives believe European plague medicines to be poisoned, 7790.
Palanpur State: People refused European treatment, 13,106.
Poona: No great objection to European medical treatment, 21,458.
Sirohi: People objected to be touched or treated, 9884–5.
Uneducated object to European medicines, 23,141.

Belladonna, by:

Incision of gland more beneficial than application of belladonna and glycerine, 11,907.
Local treatment of buboes with belladonna, 12,908.

Carbolic, by:

Carbolic acid in plague mixture believed to be of considerable value in the treatment of plague cases, 9566.
Noticeable change in the consistence of gland after a few days' application of carbolic oil, 1 in 20, 11,907.

General Statements:

Hyoscin for delirium, morphia for pain, 12,422.
Karachi: In every case in the Manora Hospital, temperature sank on the third day, whatever was the treatment, 12,307.
No definite treatment known to influence course of disease, 12,907.
No special treatment by drugs appears to do much good but good diet, warmth, efficient nursing, and treating symptoms as they arise give the best results, 2921.

MEDICAL TREATMENT, EUROPEAN—*cont.*

Statistics of treatment with combination of internal antiseptics, carbolic, and quinine, according to formula given, effect on temperature marked, 11,905–11,907.

In:

Anand: Routine of hospital treatment, 14,114.
Ankleshwar Hospital: The high percentage of recovery due to free use of stimulants, good feeding, and good nursing, 14,443.
Calcutta: Medical Hospital: No marked results from Medical Hospital treatment, 10,496.
Dharwar and Gadag: More cures in hospitals than anywhere else, 26,550.
Mysore City: Gratuitous treatment by Europeans provided by the State, 24,960.
Parel Hospital, Bombay: General treatment, I. 497–505.
Panjab: Formula of favourite plague mixture, 10,218.
Villages: No arrangements for medical attendance, 1663.

Perchloride of Mercury, by:

Injection of perchloride of mercury into the gland gave such bad results that the experiment had to be abandoned, 1862.
Perchloride of mercury in large doses, with stimulants and careful nursing, gives better results than drugs, 22,372.

Steam, by:

Steam treatment recommended by Mr. Leslie and Dr. Twigg, Vol. III., App. A.

Stimulants and Sedatives, by:

Cardiac and vascular stimulants combined with careful nursing recommended, 15,315.
Keeping up the circulation only useful treatment, 21,018.
Stimulants: No medicine of any avail except heart stimulants, 432.
Stimulants first, then aperients, 1860.
Stimulants: In Calcutta hospitals sedatives and stimulants given, I. 471.
Strychnine, ammonia, and brandy as stimulants, 11,907, 12,309.
Strychnine, digitalis, and carbolic acid mixture used in N.W.P., 9566.
Strychnine, nux vomica, and digitalis, recommended as stimulants, 12,906.
Strychnine useful in helping people to get over the attack, 12,420.
Strychnine, use of, inadvisable, I. 521.

MEDICAL TREATMENT, NATIVE:

Branding of buboes resorted to by natives, 580.
Branding of the bubo generally applied for by the native poor, 25,489.
Common native treatment is rubbing the patient with oil of sandal-wood and ashes, II. 363.
Davur, Mr., new suggestions for the treatment of critical plague cases, III. 44, 45.
Frogs applied to the buboes give great relief, 25,456.
Leaches applied to buboes, 9253.
Native receipt for external, III. 297.
Sulimani's Pills: Plague statistics relating to 15 villages where Mr. Sulimani's pills were used, II. 259*b*.
Sulimani's Pills: Plague statistics relating to 56 villages in Baroda in which were not used, II. 259–60.
Sulimani's Pills: Table comparing mortality in Baroda City before and after use of, II. 260.

MEMONS:

Karachi: Plague confined in the last few months of second epidemic to Cutchi Memons who occupy the garden quarter, 12,456.
Memons little liable to infection, 11,898.

MERCHANDISE:

Discovery of Bacillus of Plague in:

Cotton: Alleged infectivity of Vol. III., App. LXVIII.
Cotton: Allegation regarding infectivity of cotton made on insufficient ground and without bacteriological evidence, 24,575–87, 24,820–94, 24,922–5, 25,903–9.

MERCHANDISE—*cont.*

Plague bacillus not found in sacks or other articles of merchandise, 995.

Infection by:

Bangalore: Hides suspected of bringing plague, 3222.
Bangalore: Jail prisoner infected by twine, 3482, 3486.
Bombay: Suggested infection by Chinese crackers and goods imported from Hong Kong, 17,760, 19,016.
Calcutta 1896: Child plays on bale of cloths, dies of suspected plague, 7115.
Calcutta: Suggestion that plague brought in 1898 by infected articles, not by persons, 6882.
Hubli: Suggested re-infection by merchandise from Bombay, 2441.
Karachi: Plague supposed to be brought by cargo or rats, 12,984.
Karachi: Possible cause of infection by merchandise, 12,220.
Village said to be infected by cart load of tobacco from an infected village, 22,680.

Risk of Infection by:

Cargo on board of ships not a source of danger, 12,247.
Great risk of infection by cargo, 12,215–16.
Karachi: Importation of rags, hides, bones, and hair prohibited, 2202.

See Grain.
,, Gunny bags.

MERCHANTS.

See Banniahs and Traders.

METEOROLOGICAL CONDITIONS:

Bangalore: Chart showing relation between temperature humidity and plague, App. LXXI.(III), in Vol. III.
Baroda: Observations on meteorological conditions and plague, 15,238–46.
Barometrical pressure, when highest, mortality from plague greatest, 18,751.
Bombay: Charts of meteorological conditions, season, and plague mortality, Apps. LXXVII., LXXVIII., and LXXXIV. in Vol. III.
Bombay: First two epidemics stopped about the same time, 26,116.
Bombay: Meteorological conditions just before the advent of plague, 26,105.
Calcutta: Something in the environment of, inimical to the spread of plague in epidemic form, 7,627.
Cutch Mandvi: Cases went up in numbers when there was a Scotch mist or heavy due, 13,485.
Daman: During misty weather plague cases became more numerous and broke out in different places, 16,646.
Deficient rainfall and temperature in Bengal before outbreak of plague, 6874.
Doubtful whether the weather has any influence on the progress of the epidemic, or the disease itself, 11,834.
Hyderabad (Sind): Climate favourable for combating plague, 18,142.
Investigation at Kolaba Observatory to show the relationship between the surface evaporation and the mortality from plague, III. 111–3. Vol. III., App. LVIII.

See Cold Weather.
,, Hot Weather.
,, Rains.

MICE:

Death of, during Plague:

Die spontaneously during plague at Bangalore, 3594–5.
Died in numbers in the Pydhownie Police Office, Bombay, 908.
Died during plague in Timmencherla, 5047.
Mice reported affected in Porbandar before men, 13,700.
More mice than rats affected in Porbandar, 13,699.
No deaths among mice in the Panjab, 10,136.

MICE—*cont.*

Possible case of infection contracted by a woman in Karachi from a mouse, 11,422.

Susceptibility to Plague:

Experiments with mice, 8604, 8665, 8677.
Mouse fed on spleen of plague rat, died in 2 days. Spleen and liver full of plague bacilli, 26,324.
Mice very susceptible to plague virus, artificially administered, 26,322–8.
Results of injections of infected substances in mice, 8592.

See Virulence of bacillus of plague.

MICROSCOPIC APPEARANCE OF BACILLUS OF PLAGUE:

Identification of Bacillus of Plague by:

Appearance of bacillus under microscope, 5238–42.
Differs very considerably in different plague bacilli, 5738–9.
Difficult to identify by microscope alone, 8441.
Microscopic appearance not sufficient for identification, I. 465, 8527–9, 8592, 26,402.
Morphological characters of microbe very untrustworthy, 8516–7.

See Bacteriological characteristics of bacillus of plague.
,, Soil: *Assertion that bacillus easily found by microscopic observation only in soil by Hyderabad plague officers.*

MILK:

Always boiled before use, 4926.
Condition of milk supply in Bangalore; cows kept in dirty condition at Bangalore, 4900.
Milk before use mixed with contaminated water, I. 179.

Life of Bacillus of Plague in:

Bacillus of plague grows slowly in milk. 156.
Dies in milk, when sour, 3666.
Infection through milk with contaminated water 4,914.

MONKEYS:

Buboes and plague bacilli found in the cases of:

Bacillus discovered in 9 monkeys out of 26 examined from Hardwar, Kankhal, and Jawalapur, 8527, 8590.
Bubo found in groin of dead monkey at Ankleshwar, 14,504.
Buboes found in the axilla and groins of monkeys at post-mortem, 9462, 9576.
No superficial wounds found in monkeys dead of plague in parts connected with the inflamed glands, 8685.

Death of, from Plague:

Affected by plague, I. 378.
Ankleshwar: Die of plague, 14,503.
Ankleshwar: Monkeys died of plague, 14,243, 14,503.
Baroda: Monkeys die of plague, 14,641, 15,381.
Brown monkeys not very susceptible to plague, 26,012.
Brown monkeys affected in Dhawar, 23,604.
Dhunadra: Two die of plague, 14,079.
Grey monkeys being more timid than the brown keep away from houses, and thence escape infection, 23,606.
Hardwar: A few attacked by plague, 93.
Hardwar: Die of plague; grey kind more susceptible than brown, I. 378.
Hubli: Die of plague, 2444, 3113–5.
Kankhal: Plague among monkeys, and measures taken to deal with them, 9119–28, 8739–45, 8778–9.
Palanpur State: No evidence of monkeys having been attacked by plague, 13,155.
Thana: Several monkeys found dead in evacuated villages, 19,643.

MONKEYS—*cont.*

Experiments on:

Details of experiments on monkeys by inoculation of plague virus, channels by which infection can be communicated to monkeys, 26,238–47, 26,318–21.
Easily affected with plague pneumonia in laboratory experiments, 22,362.

Œdema in:

Œdema observed on the front of the trunk of three monkeys dead of plague, 9577.

Spread of Plague by:

Conveyance of plague from Kankhal to Jagjitpur, possibly through monkeys, 9363.
Monkeys go to houses for food, and may get and spread plague in doing so, 14,514, 19,643.
Monkeys may help to spread plague, 22,064–6.

MONSOONS.

See Rains.

MORIBUND PATIENTS.

MORPHOLOGY OF BACILLUS OF PLAGUE.

See Bacteriological characteristics of bacillus of plague.

MORTALITY, PLAGUE:

See Case mortality.

MORTALITY, PLAGUE: EFFECT OF INOCULATION ON.

See Inoculation with Haffkine's plague prophylactic.

MOTILITY OF BACILLUS OF PLAGUE:

Difference of opinion regarding, 5,790.
Feeble, noticed in hanging drop preparations, 5598.
Non-motile, plague bacillus being, cannot spread through floors, 8575.
Penetrates to a certain depth into floors by growth, 11,457.

MUD FLOORS.

See Floors.

MUD HOUSES.

See Floors.

MUMPS.

See Pestis Minor.

NAPHTHALINE:

Action of naphthaline on bubonic microbe, II. 5.

NATIVE PRACTITIONERS:

Notification of Cases by:

Certificates of death of qualified native practitioners of the Assistant Surgeon Class might be accepted, 8012, 26,760–9.
Information frequently obtained from native doctors, 7696.
Native doctors in league to conceal cases in Calcutta, 7669.
Native doctors lose practice if they report cases, 6796, 7692.
Native practitioners often give false certificates, 2616.
No assistance in tracing plague given in Dharwar by native practitioners, 1638.
Plague returned as asthma by native doctors, 7672.
Reports of cases by native doctors very unreliable, 7602, 25,552
Reports of deaths by native doctors no use for statistics, 21,991.

Qualification and Registration of:

Considerable number of fairly qualified practitioners in some towns, 8012.

NATIVE PRACTITIONERS—*cont.*

Notification of plague cannot be accurate without enormous increase of qualified practitioners, 7792, 26,734.
Suggestion for the registration of native medical men on the English system, 25,294.
Unqualified native medical men in Calcutta wholly unskilled, 6635.

NITRIC ACID:

Results of experiments, II. 8.

NITRIC PEROXIDE:

Used as disinfectant, statistics of results, II. 258.

NORTH WESTERN PROVINCES:

Places infected in:

Hardwar: First detection of plague on 8th April 1897, 8761.
Hardwar: First case detected in a lodging-house frequented by Sindis, where there had been illness for a month before date of detection, 9025.
Hardwar: Importation into lodging-house where first case found probable by people from Sind, 9028.
Hardwar: Existence of plague probable for some time before its detection, 8761, 8764, 9028.
Hardwar: Importation in bags of bones sent by post from Karachi suggested, 9456–8.
Hardwar: Importation in clothes by people from Sind suggested, 6435.
Hardwar: Importation by person suffering from plague or carrying the virus in his clothes suggested, 8911.
Hardwar: Probability of importation of infection from Sind in a manner which could not be traced, 9027.
Hardwar: Statement of the plague cases that occurred at Hardwar, 9064.
Hardwar: List and details of cases, II. 39.
Hardwar: No arrangements possible to prevent inter-communication between Hardwar and Kankhal, 8782.
Hardwar: Cases in spring 1898 imported from Jawalapur, but without spread of disease, 9059.
Jagjitpur: No data to account for the outbreak at, 9137.
Jagjitpur: Suggested conveyance of plague from Kankhal by monkeys, 9363.
Jamalpur: First case daughter of a man who had been to Jawalapur to buy grain, 9150–4.
Jamalpur: History of epidemic and list of cases, 9155–72.
Jawalapur: Jawalapur much more densely populated than Kankhal or Hardwar, 9018.
Jawalapur: Impossibility of tracing the source of infection, 9173.
Jawalapur: List of plague cases, II. 45–8, (9178).
Jawalapur: List of the first 12 cases, with references to the position of the houses in which they occurred, II. 539.
Kankhal: After epidemic ceased a few cases imported from Jawalapur, 9226.
Kankhal: Case of Kisham Ram probable cause of outbreak at Kankhal, 8767, 9066–9.
Kankhal: First cases occurred among the Acharaj, 9458.
Kankhal: List of 61 cases with remarks, II. 42–3.
Kankhal: Notes on the most interesting cases during the outbreak, II. 40.
Kankhal: Rats died in June, but no verified cases till September, 9072–3.
Kankhal: Mortality among monkeys, and measures taken to deal with these animals, 8739–45, 8778–9, 9119–28.
Population and situation of Hardwar, Kankhal, and Jawalapur, 9003, 9016, 9018, 9212.
Villages attacked near Hardwar, 9133.

NOTIFICATION OF DISEASE:

Notification of Sickness at Poona:

All cases of sickness notified to medical officer in charge of a ward, 21,333–5, 21,341–4, 21,528, 21,772.

NOTIFICATION OF DISEASE—*cont.*

Cases detected by corpse inspection not seen before death, 21,444–5, 21,477–84.
Corpse inspection most useful, but sick visitation cannot be dispensed with, 21,382–8.
Failure to report not punished, but persons who report granted concessions in the matter of segregation, 21,557–60, 21,884–6.
Half the cases notified by the people themselves; half notified by volunteer search parties, 21,348–52.
Half the people who are sick do not report themselves, 21,451–7.
Means of information regarding cases not seen in life, and first detected by corpse inspection. Medical officers of wards do not visit cases of sickness reported by native doctors, 21,984–999.
Medical officers do not attend during the night, but go as soon as possible to examine cases of sickness reported, 21,336–9.
Most of the corpses seen in corpse inspection have been seen under sick notification rules when alive, 21,353–5.
No penalty for not reporting sickness, 21,425.
Number of cases of plague detected by sick notification, and the advantages of the system, 21,887–901.
Number of cases reported by relatives, doctors, and volunteers, 21,872–83.
Number of plague cases detected by sick visitation, 21,377–81.
People notified sickness willingly, and had no objection to their women being seen, 19,930–3.
People ready to report, and most cases of sickness reported, 21,595–604.
People report the majority of cases of sickness, 21,513–7.
People willing to report sickness, but in many cases death takes place too quickly to enable them to do so, 25,842–3.
Two-thirds of cases seen in corpse inspection not seen by any doctors during life, 22,007.
Very few cases in which examination of the sick has been objected to, 21,340.
When plague was rife only diagnosis was whether the case was one of plague or not; afterwards the disease from which the sick person was suffering was diagnosed, 21,346–7.

Opinions and Recommendations regarding:

Agency for, very unreliable in India, no one compelled to send in a report except in the municipalities, 6083.
Cannot be accurate without enormous increase of qualified practitioners, 7792.
Employment of Assistant Surgeons, but not of Hospital Assistants, in the Sanitary Department would improve notification of disease, 3964–83.
Employment of Assistant Surgeons or Hospital Assistants in the Sanitary Department would probably improve notification of disease, 23,303.
Law of notification of contagious diseases as it is carried out in England would be impossible in India, 21,855.
Notification of diseases should be made compulsory, 17,747.
Notification of sickness not possible, as at present 90 per cent. of the people die without being seen by a doctor, 21,856.
Special forms of reports of sickness recommended, 23,298.
Voluntary system of registration of sickness should be established in Bombay and other large places, 10,990.

See Medical Treatment, European: *Attitude towards, in general.*
,, Native practitioners.
,, Voluntary agency.

Systems of:

Ahmedabad: No regular system of notification of diseases, 13,873.
Bombay Presidency: Notification of deaths not general; chiefly a matter of police, 17,229.
Calcutta: Supposed to be compulsory; not effective, 6506.

NOTIFICATION OF DISEASE—*cont.*

Cholera promptly notified, 7818.
Dharwar: System of notification of deaths, 1623–40.
Headman of village only means of information of deaths and sickness for rural areas, 22,959.
Municipalities: Penalty for the non-notification of disease never enforced, 23,311.
No notification law in India, 6089.
No system of notification of infectious disease in Bombay, 17,228.

NOTIFICATION OF PLAGUE:

Attitude towards:

Bombay: Cases not notified owing to difficulty of recognising plague, 1050.
Dharwar: No information to be obtained, 6133.
Difficulty of getting information owing to the temper of the people, 7598.
Errors in notifying plague in rural district owing to the difficulty of recognising the disease, 23,289.
Hubli: Cases notified mainly after death, 19,836.
N.W.P.: Cases not reported from sheer ignorance, people failing to recognise plague, 8867.
Objection to plague measures so great that people will not report cases, 7824.
Surat: Compulsory declaration of plague easily evaded, 15,582.

Early Notification, Importance of:

Early notifications impossible in India without very large increase of the existing machinery, 10,499.
Early notification most important, 10,497.
Early notification of primary importance, 22,945.
Early notification the most important thing, I. 408.
First cases rarely come to official notice anywhere,
N.W. Provinces: Prompt reporting of cases the object of some of the plague regulations in the N.W. Provinces, 8749.
Panjab: Early notification of disease encouraged by a system of rewards and punishments, 10,826.

Efficient Notification secured:

Belgaum: The fear of Government measures being removed, people willingly give notification of plague, 23,138.
Bombay: In some of the districts in Bombay people voluntarily notify plague, 17,868.
Enemies of patients give information of cases, 6598.
Hyderabad (Sind): People give early notification of cases, 18,394.
Karachi (Kiamari division): Ready reporting of plague cases by people, 11,980.
Ready compliance with orders for notification the results of former experience, 24,519.
Sukkur: At first notification not prompt, but improved later, 18,394.
Surat: Dread of segregation works as pressure on neighbours to give early notification, 16,030.
Surat: Incumbent on head of family to report sickness within 24 hours, 15,836, 16,030.
Surat: Concessions regarding disinfection and segregation induced people to notify sickness, 15,715, 16,004, 16,031–2, 16,036.

Notification not Efficient:

Bombay: Mild cases of plague escape notification, 1192.
Cutch Mandvi: Muhammadans opposed to, 13,581.

Special Rules for Notification of Plague:

Bombay: Measures adopted to obtain early information of plague and their result, 25,574–617.
Bulsar: Notification of plague and corpse inspection compulsory, 16,169.
Calcutta: Native practitioners found to report plague to Plague Officer, 6791–3.

NOTIFICATION OF PLAGUE—*cont.*

Calcutta: Under plague regulations all cases to be reported, under penalty, 6791.
Cutch Mandvi: Penalty of fine imposed for neglecting to report cases, 13,552.
Palanpur: System introduced in the villages ensured daily reports and early information of all sickness and deaths, 13,128.
Rohri: Notification of all fever made compulsory, 12,026.

NUTRIENT MEDIUM IN HAFFKINE'S PLAGUE PROPHYLACTIC.

See Haffkine's plague prophylactic, *character and preparation* and *constituents of.*

OBSERVATION CIRCLES:

Inspectors visit every village in Madras observation circles once a week, 3954–5.
Madras: General rule that no one shall be detained more than 10 days, 3961.
Observation system in Madras obtains prompt discovery of cases, 3881.
Observation circles on Madras frontier, I. 145–9.
Observation circles 10 miles drawn in double rows along Madras frontier, 3865.
Observation system of Madras unique as regards rural areas, 3916.
People arriving within the circles in Madras report themselves for 10 days; few omissions, 3929–35.
Village headmen bound to question and report persons arriving in Madras observation circles and without pass, 3946.
Where plague has broken out, number of Madras observation circles increased and their area contracted to five miles diameter, 3947.
See Surveillance.

OCCUPATIONS:

Influence of Occupation on Liability to Plague:

Incidence of plague on various occupations at Bombay, I. 392–3.
Karachi: One thousand seven hundred and five cases of plague classified according to the occupation of the sufferers, 11,727.
Preponderance of plague cases in men due to their occupations exposing them more to infection, 12,349.

See Acharj.
,, Banniahs and Traders.
,, Corpse bearers.
,, Dhobis.
,, Disinfectors.
,, Domes.
,, Scavengers.

Influence of Outdoor Life on Liability of Plague:

Beggars at Satara, living all day in the open air, escaped plague, 22,267.
Bhils suffered little on account of their leading an open air life and residing on the outskirts of the town, II. 246.
Herdsmen and shepherds have almost a perfect immunity, 5473.
Open air life and occupation of people living in fishing villages near Karachi keep them free from plague, 12,278–86.
Outdoor occupations do not make people less liable to plague. Instance, the people at Salaya, 13,476.
People working in air all day and sleeping out all night have few cases, 17,711.
Rice cultivators at Satara, living and working in the open, escaped infection, 22,127, 22,184.
Waghris and gypsies live in grass huts outside Cutch Mandvi and suffered little from plague, 13,480.

See Air and light.

ŒDEMA:

Clinical Feature of Plague:

Common symptom in the lungs in pneumonic plague, generally observed on third day of illness, 20,823.

ŒDEMA—*cont.*

Never observed œdema on the chest with pneumonic plague, but in many cases of inguinal and axillary bubonic plague, 27,179.
No œdema at the anterior portion of the body observed in plague patients in the hospital at Ahmedabad, 13,944.
No exceptional œdema of the thorax or abdomen noticed in patients in the Sassoon Hospital, 12,924–5.
Œdema never seen confined to the anterior part of the body, 12,407.
Œdema of the surface very rare, 12,403.
Several cases of œdema on the anterior and posterior wall of the body, 18,059.

In Animals:

Œdema on front of trunk noted in three monkeys died of plague, 9577.

Post-mortem Appearances:

Doubt, till bacteriological examination, whether case with œdema was plague or not, 9552–3.
No œdema in the anterior wall of the chest after death from pneumonic plague, 15,926, 18,158–61, 20,021.
No œdema of the surface either before or after death, 18,557.
No œdema in plague corpses except in contiguity of buboes, 10,643.
No œdema in cases of exclusively inguinal buboes, 10,347.
No œdema in front of thorax and abdomen seen independent of buboes on neck, 10,379–83.
No œdema observed at post-mortem in cases of pneumonic plague, 8669, 9891.
Œdema never observed in the subcutaneous tissues at the front of the body, 10,424–9.
Œdema of the thoracic surface invariably observed at post-mortems, but never in face, hands, or feet, 9544–9.
Œdema observed in several cases of pneumonic plague, 10,346.
Œdema of the chest and upper limbs very common after death, 10,345.
Œdema occurring in the last hours of life never observed in autopsies other than plague, 9546.

OPIUM:

Immunity from plague of opium smokers and eaters, III. 43.

ORIGIN OF PLAGUE, THEORIES REGARDING:

Mr. Davur's theory of the origin, spread, and treatment of plague, III. 42–5.
Mr. Desai's theory of the origin of plague, 14,767.
Mr. Ghadiali's theory that plague is merely the child of other causes more powerful than the simple bacillus of plague, 24,935.
Opinion that the plague bacillus does not originate plague, but is merely a symptom of the disease, 8314.
Prof. Gajjar's theory of the origin and causes of plague, 18,622–49.

OTHER DISEASES:

Decrease in malarial fever during plague, 12,993, 16,505–7.

See Inoculation with Haffkine's plague prophylactic.

OVER-CROWDING:

Existing Conditions:

Ahmedabad: Very much over-crowded, 100 persons to the square acre in, 13,938.
Bangalore: Much over-crowded; some divisions contain a population of 8,000, while there is only room for 3,000, 2560.
Bombay: Average population of rooms in Bombay, 5 persons; Muhammadan quarters less over-crowded, 844.
Bombay: Density of population varies from 7 square yards to each person to over 800 square yards in the extreme suburbs, Bombay, 25,674.

OVER-CROWDING—*cont.*

Bombay: Excessive over-crowding and dirt in the chawls, 16,985, 17,711.
Bombay: Houses in Bombay contain several families of outcasts in one room, 833.
Bombay: In one chawl 2,000 to 2,500 persons in 300 rooms, 17,289.
Bombay: Kamatipura: Houses low and badly ventilated as well as over-crowded, 17,834.
Bombay: Mandvi: Houses large and well-ventilated, but much over-crowded, 17,934.
Bombay: Muhammadan quarters less over-crowded, 844.
Bombay: Outcasts living in Moorland Road in very crowded rooms, under conditions favourable to plague, 25,784.
Bombay: Over-crowding in Bombay a blot on its municipal system, 17,688.
Bombay: Over-crowding in Bombay, new municipal regulations, 133, 878.
Bombay: Over-crowding in the suburbs not so bad as in the town, 25,677.
Bombay: Over-crowding worse than any seen anywhere else, 26,644–5.
Bombay: Statistics regarding density of population, 883, 25,667.
Calcutta: Bustees occupied by 200 people or more, 7707.
Calcutta: Great overcrowding in parts, 6861.
Cutch Mandvi: Very much congested even in ordinary times, 13,349.
Hardwar: Inspection of lodging-houses very strictly carried out and number of occupiers limited, 9007.
Hinganghat: Over-crowding, but no worse than in other parts of India, 6278.
Hubli: No remarkable over-crowding, 20,209.
Karachi: Over-crowding exists to a terrible extent, especially among the weavers, 22,649.
Nasik and Malegaon: Over-crowding a tendency of the poorer classes, 13,785.
Nasik: Not much over-crowded, 16,979–84.
Surat: Houses of Golas, who suffered most, over-crowded, 16,107–8.

Improvement of Conditions of Over-crowding:

Bangalore: Over-crowding to be limited by law, 3265.
Bombay: Lord Sandhurst's scheme for the restriction of over-crowding highly approved, 17,688.

Influence of Over-crowding on Plague:

Ahmedabad: Plague worst where crowding least, though houses bad, 13,963–85, 13,990–1.
Bangalore: Relationship of over-crowding to mortality, 2590.
Bombay: Epidemic in Bombay increasing during cold weather owing to the people sleeping more indoors, 26,104.
Bombay: More sparsely populated districts of Bombay City most severely attacked, 8707.
Bombay: Mortality from plague in the most densely populated portions of Bombay less than in small villages in the suburbs, 25,675.
Bombay: Mortality in the sanitary Byculla Jail greater than in some over-crowded chawls, 25,682.
Bombay: Suburbs attacked have old houses and were crowded at time of attack, 25,690–8.
General vitiation of the air by over-crowding, &c., the predisposing conditions to plague, 17,354.
Great difference in the intensity of plague in ill-ventilated, over-crowded houses and well-ventilated houses, 14,390–1.
Karachi: Fishing villages close to Karachi where people live in open air and huts not over-crowded remained free, 12,279.
Karachi suffered most in the over-crowded weaver quarter, 22 649.
Northerly and easterly winds, by causing over-crowding, have an unfavourable influence on mortality in Bombay, 26,103.
Over-crowding and bad ventilation the causes of the disease, 14,716.
Over-crowding and plague diminished in the hot weather because the people sleep out of doors, 14,385.

OVER-CROWDING—*cont.*

Over-crowding, lowering of the vitality, habitual disregard of hygienic rules cause plague, 25,263.
Over-crowding principal factor in the propagation of the disease, 14,388.
Over-crowding the great question in Bombay in connexion with plague, 17,688.
Virulence and extension of disease dependent upon dirt, over-crowding, &c., 11,281.
Worst cases of plague in over-crowded houses, 11,228.

See Housing.

OXYDISING AGENTS:

Microbe resistant to reducing agents, sensitive to the action of oxydising agents, 8551, II. 8–10, 13.

PASS SYSTEM:

Bandra: Abandonment of the pass system and of inspection led to the introduction of plague in, 19,431.
Bangalore: Passengers forbidden to leave without pass, 2586.
Bangalore: Pass system failed; unworkable without enormous staff, 2641–3.
Baroda: Pass system very carelessly administered, 18,614–7.
Belgaum: Native resident plague authority distributed passes to villages in the district in, 23,000.
Bellary district: Valuable, 4934.
Billimora: Passes given to the uninoculated if no plague had occurred in their houses or streets, 15,066.
Daman: Frontier pass system, 15,966.
Dharwar: Pass system in force, 19,852.
Hubli: At one time no one could leave the town by rail or road without a pass, 19,812–6.
Hubli: Passes for travel by road or rail given only to persons having twice inoculation certificates dated 10 days previous to issue of pass, 3159.
Hubli: Pass system practically useless, as far as the road was concerned, 19,825.
Jalgaon: Pass system and patrolling roads failed to check spreading of plague by refugees, 25,544–6.
Karachi: No one allowed to change residence at Karachi without pass from plague superintendent, 12,277.
Karachi: People allowed to leave the place on passes, 3778–9.
Kotri: System of passes, 12,620.
Madras frontier, I. 145–9.
Madras: Headman of village notified of arrivals, 3929.
Madras: No complaints of blackmail, 3956.
Madras: One hundred and fourteen out of 5,500 with passports do not present themselves, 4224.
Madras: Pass system deficient at first, now working smoothly, 4236.
Madras: Statistics of evasion of pass system, 3870.
Madras: Very few evasions and little dislocation of trade, 3867.
Madras: Works well, 3866.
No special passes given to people travelling with large families, 12,222.
N.W.P.: Pass system adopted in, 9337.
Panjab: System of passes, 10,069.
Panjab: People allowed to leave infected places after spending 10 days in quarantine camp, 10,258.
Surat: Passes insisted on to prevent people leaving the place and spreading plague, 24,426–7, 24,461–3.
System of passes worked better with the village people than with the town people, 13,653.
Under the passport system people have to present themselves at one of the district offices for 10 days after they arrive in town, 4234.

See Camps.

PERCHLORIDE OF MERCURY:

Action on the Bacillus of Plague:

An absolutely effective disinfectant if used properly, 10,930.
Bacillus in infected floors survives the application of disinfectants, 5159.

PERCHLORIDE OF MERCURY—*cont.*

Cow-dung: Perchloride of mercury, details of experiments with, in acid solution on, 18,828–63.
Eight gallons of the 1 in 725 Bombay solution would be required to vitally damage the plague microbe at the surface of a 100 square feet cow-dung floor, 18,862.
Experiments showing efficiency in killing plague, 26,347, 26,434A.
Floor, not affected by 1 in 725 Bombay solution, infective material below, 18,862.
Floors adequately disinfected by solution of 1 in 500, 26,350.
Growth of plague bacillus stopped in plague cultures after half an hour's exposure to perchloride of mercury, 1 in 20,000, 26,347.
Increase in number of microbes, perchloride of mercury in neutral solution led to apparent, 8550, 8579.
Inert, bacillus of plague not killed, only rendered, 18,653.
Killed more rapidly in perchloride of mercury than in anything else, 7918.
Neutral solution led to apparent increase of microbes, but acid solution a reliable disinfectant, 8553–61, 8579–80.
Results of comparison with nitric peroxide, II. 258.
Result of tests with metallic salts, II. 6, 18,828.
Strong disinfecting action, sublimate in an acid solution has a, 8,554, 8561, II. 13.

Attitude of Natives towards use of:

Better classes averse to disinfection of their houses by perchloride of mercury, 15,495.
Disinfection by sublimate not objected to, 21,590.
Natives very sceptical about benefit of perchloride, 22,205.
Villagers often bribe the coolies to save their clothes from being put in perchloride solution, 21,174–5.

Disadvantages and difficulties connected with the use of:

Albuminous material is present, loses its disinfectant power, when an, 18,662.
Brass tubes, disinfecting power destroyed by applying it through fire engines with, 16,137.
Corrosive action of perchloride of mercury on metals disadvantage to its use as disinfectant, 10,018.
Expense: Kiln system cheaper than disinfection with perchloride, 19,677.
Expense: Perchloride of mercury expensive, 13,192.
Floor: Question whether in practice sufficient quantity of perchloride could be used to properly disinfect, 8578.
Lime applied every day to the rooms in which patients were left to be treated at home in Bombay, perchloride being applied from time to time on top of the lime, 25,798.
Lime: Good effects of perchloride of mercury liable to be counteracted by addition of, 20,212.
Lime: Mixed with, at Guntakal, before application, 5100–8.
Lime salts contained in many waters throughout India, perchloride solution rendered inert through the, 10,016.
Limewash neutralises disinfectant effect, mercury and acid upon, 8658.
Mercurial poisoning, generally not noticed among disinfectors, 10,020, 18,632, 19,939; but said to have occurred in 2 cases from clothes disinfected in perchloride, 16,117, 16,120–32.
Methylene blue added to perchloride useless for controlling the work of disinfectors upon mud walls, 9997.
Mud introduced into and weakened the solution in Satara because the coolies would place the pumps used on the ground, 22,323.
Poona: The native salt procured from the bazar found very impure, 21,305–10.
Purity of perchloride used in Bombay shown by analysis, 25,535.

PERCHLORIDE OF MERCURY—*cont.*

Disinfection, used for:

Bangalore: Perchloride of mercury used at, 2698.
Bombay: Perchloride of mercury chiefly used in strength of 1 in 1000, 911, 940, 1345.
Calcutta: Perchloride used with small pumps at, 7297, I. 471.
Calcutta: In acid solution, perchloride of mercury adopted at, 6528.
Calcutta: Perchloride of mercury adopted instead of carbolic acid at, 6528.
Calcutta: Mayo Hospital chiefly disinfected with perchloride at, 7022.
Jawalapur: Disinfection by perchloride used at, 8934.
Kalindri: Resorted to as disinfectant, 9894.
Kotri: Disinfection by perchloride, 12,536, 12,562.
Madras: Perchloride used in, 3937.
Palanpur: Perchloride resorted to as disinfectant, 13,091–4.
Panjab: Perchloride first used, but given up for phenyle, 10,016.
Poona: Perchloride of mercury solely used as disinfectant at, 10,933.
Rohri: Disinfection by perchloride, 12,029.
Umreth: Disinfection by acid perchloride still going on, 14,049.
Use of, prescribed by the Government of India, 7859.

Disinfection of Clothes by:

Clothes disinfected with perchloride for five or six hours, 1873–4.
Clothes soaked in perchloride to disinfect, 2707.
Clothes steeped in perchloride for disinfection at railway stations, 1315.
Clothing of people detained at Ahmedabad station disinfected by immersion in a solution of perchloride of mercury, 1 in 1,000, to which common salt was added, 13,894.
Dharwar: Clothing of patients leaving hospital disinfected with perchloride, 1872–4.
Dharwar: Clothing of persons from infected houses disinfected with perchloride, 2329.
Lanauli: Clothes disinfected in perchloride, 20,200.
Perchloride of mercury forced on clothes and houses with Chinese pumps at Dharwar, 2329–32.
Poona: Acid not used in the solution as all clothes disinfected, and acid spoiled clothes, 10,931.

Disinfection of Houses by:

Ankleshwar: Houses disinfected with perchloride of mercury in a hydrochloric solution, 14,258.
Baroda: Perchloride used to disinfect infected houses only, 14,631.
Bombay: Used in, 911.
Calcutta: Acid solution used for house disinfection, 6528–31.
Dharwar: Perchloride forced on houses with Chinese pumps, 2329–32, 2345–50.
Guntakal: Perchloride applied to roof and walls as disinfectant, 5099, 5100.
Hardwar: Houses disinfected with perchloride, 9030.
Karachi: Infected houses, and houses where dead rats had been found, disinfected by perchloride 1 in 1,500 in acid solution, 11,448, 11,647.
Poona: Perchloride solution used in disinfecting houses from roof to floor, 10,927.
Satara: Perchloride pumped on to walls, roof, and ceilings, 22,322.
Surat: Houses opened up, swept out, and doused with perchloride solution, 24,434.
Surat: Perchloride of mercury used only for infected houses, 16,011.
Umreth: Golas quarters disinfected by perchloride and kiln burning, 14,037.
Wardha: Houses saturated with perchloride 6124.

Disinfection of Persons by:

Patients on leaving hospital at Dharwar disinfected by pouring over them a warm solution of perchloride 1 in 1,000, 1875–6.

PERCHLORIDE OF MERCURY—*cont.*

Persons in Poona camps bathed in perchloride of mercury baths, 19,937.

Efficacy of:

Belgaum: Thorough disinfection with perchloride stops epidemic at Kagwad, 23,044.
Carbolic acid given up in favour of perchloride solution, 6528.
Disinfection with perchloride only so far useful as it cleans out the place and lets in fresh air, 22,864.
No cases at Ankleshwar from whitewashing houses disinfected with perchloride of mercury, 14,237.
No cases in Poona in houses disinfected with perchloride on return of people from camps, 10,937.
Perchloride of mercury most efficacious, 245, 10,930, 13,192.
Table showing number of plague cases after disinfection of houses with perchloride of mercury and with nitric peroxide, II. 258*b*.

Inefficacy of:

Karachi: No effective results of disinfection with perchloride of mercury, 22,658.
Lanauli: Disinfection with perchloride of mercury under careful supervision ineffectual, 20,184.
Reliance not placed solely on perchloride of mercury, 570.

See Recurrence of plague in the same house or locality.

Strength and Mixture in which used:

Acid not used in Poona on account of its effect on clothes, 10,931.
Formula of Bombay solution of acid perchloride disinfectant, 18,832.
Hydrochloric acid used in Calcutta, perchloride of mercury with, 6530.
Hydrochloric acid used in disinfecting processes at Umreth, perchloride of mercury with, 14,051.
Hydrochloric acid used instead of common salt to make solution of perchloride of mercury, 14,113.
Igatpuri: Solution made and used 10 times too weak, 23,317.
Perchloride of mercury used in solution of 1·1000, 940.
Strength of disinfectants not always accurately made up in Bombay through press of work, 915.
Strength of solution not always accurate, 24,450.
Tests of strength and acidity of perchloride disinfecting mixture used in Bombay, 25,540–7.

PERIOD FOR WHICH INOCULATION AFFORDS PROTECTION.

See Inoculation with Haffkine's plague prophylactic.

PERIOD FOR WHICH PLAGUE BACILLUS CAN SURVIVE:

In Air and Light:

Dies in a few hours when exposed to air and light, I. 447.
Dies very soon in the open air, in articles taken from infected districts, 9296, 9297.
Grows when covered up from the light in laboratory experiments, 25,304.
Microbe establishes itself most in darkness, 9683.

In Animal Organisms and Substances:

Bacillus dies more quickly when obtained from blood than when obtained from urine, 26,337.
Bacillus disappears very quickly in the blood of rats, 17,500.
Bacillus recovered from bodies of animals up to 21 days after burial, 27,382.
Bacillus recovered from saliva 10 days after apyrexia, 25,355.
Bacillus recovered from sputum of pneumonic case up to 28 days after development of lung

PERIOD FOR WHICH PLAGUE BACILLUS CAN SURVIVE—*cont.*

symptoms, and three days after apyrexia, 25,342–6.
Bacillus recovered from throat 10 days after fever ceased, 25,312.
Disappearance of the microbe after death, the acidity developed in the bodies of persons dead of plague, may aid in causing the, II. 7; 8655, 8681–4.

In Cow-dung:

In laboratory experiments the plague bacillus lived several months in sterile cow-dung, 18,877.
In unsterilised cow-dung the microbe did not live more than six days, 18,880.

In Clothes:

Kept alive for indefinite period in clothes, 10,094.

In Dirt:

Dies in dirt, 1003.
Establishes itself mostly in dirt, 9683.
Incapable of existing in dirt, 1003–4.

In Fæces:

Bacillus of plague dies in 2½ hours in fæces, 3611.

In Grain:

Dies in sterilised solution of rotten grain, 3669.
Experiments to show that the bubonic microbe derived from pure cultures perishes within 13 days after being added to specimens of grains and seeds, II. 17.
Not recovered after seven days in grain artificially infected and then dried, 26,386.
Results of experiments with several kinds of grains and seeds on life of bacillus of plague, II. 16, 17, 18.
Results of experiments on survival of bacillus in grain mixed with the sputum of a human plague patient, II. 18.
Virulence of the microbe on grain only persistent for a few days, 8535.

In Gunny Bags:

Longest period after which recovered from artificially infected gunny bags, seven days, 26,386.

In Milk:

Bacillus of plague grows slowly in milk, 156.
Dies in milk when sour, 3666.

In Soil:

Dies in a few hours in earth when exposed to air and light, I. 447.
Experiments on the growth of the plague microbe in soil, 18,893, 26,132.
Non-sterilised garden mould, can live from four to six days in, 18,867.
Sterilised garden mould, can have a continued existence for 13 days in, 18,865.

In Water:

Lived 44 days in sterilised tap water, 19,086.
Survives application of water and disinfectants in infected floors, 5159.
The bacillus flourishes most luxuriantly when the air is moist, and in damp surroundings, 9683, 18,638.
The microbe does not remain long alive in water, 8540.

When subjected to Drying:

Desiccation with calcium chloride kills bacillus of plague in 18 hours, 26,346.
Exposing a plague culture for four days to ordinary drying does not kill the microbe, 26,345.

When subjected to Heat:

Killed by exposure for five minutes to a temperature of over 62° or 63° C., 27,379.
Plague dies at 45° C., 102.

When subjected to the Sun's Heat and Light:

Growth could not be recovered in any instance from cultures exposed to sunlight for four hours, 26,342.

PERIOD FOR WHICH PLAGUE BACILLUS CAN SURVIVE—*cont.*

Heat of the sun sufficient to destroy plague microbes, 814.
Plague-infected calico rendered sterile by exposure to sunlight, 26,342.
Three hours' exposure to strong sunlight of infected flannel, cotton wool, and cloth, greatly retards the development of the bacilli, 26,342.
Vitality of the bacillus of plague diminished by the sun, 17,031.

Vitality of Plague:

The life of the plague organisms is indefinite, 10,597.
The plague bacillus dies out without use of chemicals, 22,058.
The plague bacillus dies in time without disinfection in about four months, 22,663.

PERIOD OF EPIDEMIC:

Epidemic ceased in villages after three months without evacuation or disinfection, 22,845–8.
Normal length of the epidemic where no, or insufficient, measures are taken, 9982–3.

PERMANGANATE OF POTASH:

Efficacy of as a disinfectant for plague:

An extremely potent destroyer of the bubonic microbe, II. 9.
Cowdung, 1 gram, deoxidises ·04 grammes permanganate, II. 10.
Result of tests with, II. 9–10.
Useless in practice, as it is readily destroyed by organic substances, 8628.

Use of, in connexion with cholera:

When used in well water can check a water-born cholera epidemic, II., 10.

Use of, in connexion with plague:

Bombay: Permanganate of potash used for flushing houses with steam-engines, but given up later for perchloride, 911–2.
Khandraoni, used at, as disinfectant, 9659.
Too expensive and inconvenient for practical use, II. 10a.
Well for camp use at Anand treated with, 14,148.

PERSONS, DISINFECTION OF:

A bath of soap and water without disinfectants would equally answer the purpose, 4298, 4308.
Females: Women are attended to by a female. They are made to sit down in a tub and the disinfectant is poured over their head, 4314.
Persons disinfected by soap and water bath, 13,896.
Personal disinfection most necessary, 12,053–5.
Personal disinfection more disagreeable to the natives than the disinfection of clothes, 21,510.
People objected very strongly, 4298, 4300.
Poona: Arrangements for disinfection at, 4027.
Rules regarding disinfection of emigrants at Karachi, 12,231–3.

PESTIS MINOR:

Cases observed:

Bombay: Mild cases described, I. 380.
Bombay: Cases of mild plague in 1898 in Bombay, 18,039–46.
Bombay: Mild plague, with enlarged glands frequent among plague workers, 18,063–5.
Bombay: Pestis minor, cases observed in Bombay, 20,516–22.
Bombay: Pestis minor, observed in Bombay, symptoms described, hard to diagnose; no case of infection from such cases noted, 20,556–69, 20,573–6.
Bombay: One mild case observed at Parel, 22,349.
Bombay: Parel Hospital: Case of pestis minor in attendant in post mortem room, 22,489.
Bulsar: Observed at Kosumba in Bulsar, 26,989.
Calcutta: Pestis minor, resulting from cut at post-mortem of plague case, 7,003–9.
Hyderabad Sind: Mild cases of plague, non-infectious, observed in Hyderabad Sind, 18,096–103, 18,146–52.
Kankhal: Mild case observed in a child, 9467–78.
Khandesh: Possible cases of mild plague, 24,542.
Khandraoni: Pestis minor, case of, in child at Khandraoni, 9,678.
Pali epidemic: Observed during the Pali epidemic of 1836, 27,012.
Panjab: Boy at Gobindpur, Panjab, got mild plague from an ordinary case, 10,369.
Panjab: Mild cases at Dasanjh and Aur in the Panjab, and in other villages, 10,337–9, 10,548–50.
Panjab: Epidemic of *Kanedas* (swellings behind the ears) before plague at Garhshunker, 10,832.
Poona: Pestis minor, two mild cases observed; other cases probably malarial might be confused with plague, 7,636–52.
Poona: Mild cases, with neuralgia, among plague workers in Poona, 21,951–7, 21,967–73.
Rania: Observed at Astrachan, in Resht, 26,989.

Cases resembling Mumps:

Banga: Epidemic of mumps resembling plague before outbreak of plague, 10,235.
Bombay: Two cases in the Umarkhadi Jail, Bombay, 69 (I. 9), 7236–8.
Bombay: Mild case in Byculla Jail, Bombay, with pain in lower jaw, III., 659 (*f*).
Kankhal: Case at Kankhal, 9077, 9253.
Poona: Mild cases in Mahuli village and in Poona city, cases of mumps, of which one later developed plague symptoms, preceded the outbreak of plague, probably infective as so many children had mumps, 21,653–6, 21,664–5.
Poona: Mild cases of pestis ambulans and cases resembling mumps observed in Poona, 21,961–2.
Umreth: A case in Umreth, II. 487.

Infectiousness of Pestis Minor:

Coryza associated with plague, 21,006.
Coryza: Plague infection, spread by cases of coryza, 20,394–401, 20,532–6.
Mild case at Gobindpur, spread the disease and a case infected from a mild case was a serious one, 10,099.
Mild case, instance of possible infection from, 18,059–62.
Mild case, instance when infection was carried by a, 24,117–8.
Mild cases probably infectious, 7649, 9422–26.
No evidence of mild cases being infectious, 14,749.
Possibility that mild cases act as a connexion between epidemics, 27,000.

PETECHIÆ:

Clinical Feature of Plague:

Petechiæ not a characteristic sign of plague, 20,833.
Petechiæ not observed in pneumonic form, I. 369.

PETECHIÆ—*cont.*

Post-mortem Appearances:

Petechiæ always found post-mortem, 1420.
Petechiæ sometimes on the capsule of the kidneys in bubonic plague, 10,421.
Petechiæ of the stomach a noticeable feature in post mortems after bubonic plague, 10,419.
Petechiæ not seen on the skin, frequently on internal viscera, 9572.

Prognosis, As:

Petechiæ sign of bad prognosis, I. 352.

PHENYLE:

Action on Bubonic Microbe:

Action of phenols and their allies on the bubonic microbe, II. 4*a*, 5.
Doubtful whether phenyle and izal are capable of killing microbe under natural conditions, II. 5.
Phenyle more active than carbolic acid, II. 5.

Attitude towards:

Banga: Phenyle favoured by people, 10,306.
Disinfection of clothes by phenyle objected to by owners, 10,307, 10,817.

Clothing disinfected by:

Clothing dipped in phenyle and spread out in the sun used as disinfecting method, 10,048–9.
Disinfection of clothing by a five per cent solution phenyle, 11,452.

Houses flushed with:

Bombay: Infected buildings flushed with a solution of phenyle or permanganate of potash, 911.
Bombay: Given up for perchloride in, 911.
Calcutta: At first used for spraying houses, but afterwards given up for perchloride, 6520–28.
Khandraoni: Used for houses at, 9659.
Panjab: Phenyle, 1 in 200, used for disinfecting houses, 10,022.

Persons disinfected by:

Bombay: Convalescents bathed in phenyle on leaving hospital, 559.
Panjab: Before leaving evacuation camps, inmates bathed in phenyle, 10,049, 10,235.
Panjab: Disinfecting gangs bathed in phenyle on leaving work, 10,003.
Poona: Persons bathed in phenyle and similar disinfectants, 4027, 10,235, 21,273.
Strong solution of phenyle stings the skin so much that people cannot stand it, 4300.
Tungabadhra: Persons bathed in phenyle at, 4513.

PIGEONS.

See Birds.

PIGS:

No appearance of sickness in pigs, although great numbers were at large in the streets of Daman, I. 378.
Pigs were affected with plague in Daman, 16,355, 16,548.

PILGRIMS:

Cashmere pilgrim ship left Karachi carefully inspected; no cases on board, 12,262.
Nasik a great centre of pilgrimage, 13,751.
No pilgrims sail from Karachi to form caravans to Mecca, 12,266.
Pekin pilgrim ship left Bombay in December 1896, before pilgrim traffic stopped; plague occurred on board, 752–4.
Saharanpur: General inspection of pilgrims from Bombay and Sind, 9021.
Suggested infection of Bombay by pilgrims coming from Kumaun to Nasik Fair, 1545, 1551.

PHOTO-MICROGRAPHS OF BACILLUS OF PLAGUE.

Photo micrographs of bacilli made in connexion with cases of suspected plague in Calcutta in 1896, III. 369–376.
See Microscopic appearance of bacillus of plague.

PLAGUE PROPHYLACTIC:

See Haffkine's plague prophylactic.
,, Inoculation with Haffkine's plague prophylactic.
,, Yersin's curative serum.

PNEUMONIC PLAGUE:

Clinical Features:

Acute pneumonia a complication of plague, 10,212.
Brought to notice first in September 1896, 19,170–4, I. 375.
Course of typical pneumonic plague, I. 381.
Details of pneumonic cases, II. 63*b*, 64*a*.
No buboes in cases of, 12,918.
Pneumonic plague rarely with buboes, 2378.
The plague bacillus always recoverable from blood of patients dead of pneumonic plague, 17,258.

Diagnosis of:

Absence of inflammation of the pleura a marked difference between croupous pneumonia and plague pneumonia, 9568.
Cases may readily escape detection if attention directed only to presence of buboes, 13,945.
Diagnosis of plague pneumonia impossible without bacteriological or at least microscopical examination, 12,476.
Difficult to distinguish between plague and ordinary pneumonia, 12,469.
No certainty of pneumonic plague without post-mortem examination, 9435.
Pneumonic cases discovered by the stethoscope and physical examination of the lungs, 12,911.

Efficacy of Inoculation in:

Percentage of recoveries, inoculated and uninoculated, in pneumonic plague, 2382.

Fatality of:

All pneumonic cases in Anand Hospital died, 14,120.
Children: Pneumonic plague always fatal in, 12,413.
Great mortality in pneumonic form, 13,040, 15,176.
Non-bubonic type characterised by pneumonic engorgement of the lungs and accompanied by extreme prostration most fatal, 15,274.
Percentage of recoveries, inoculated and uninoculated, in pneumonic plague, 2382.
Pneumonic plague generally fatal in 48 hours, 2379.

Infection: mode of:

Pneumonic form infectious through the air, 12,359, 17,775, 18,111, 18,174.
Pneumonic plague infectious through the air by inhalation, I. 351, 20,622, I. 369.

See Sputum, *spread of infection by.*

Infectiousness of Pneumonic Plague:

Direct infection from patient to patient probable in pneumonic plague, 8663.
In rooms where cases of pneumonic plague treated, nurses and attendants suffer, except in properly arranged hospitals, 18,008–11.
Many instances of infection from pneumonic cases noted, 504–8.
More than one case of pneumonic plague noted in the same house—is the more contagious form of plague, 19,201–4, 19,218–20.
Plague pneumonia easily given to monkeys by the Russian Commission by spraying solution of virus in the air of the monkeys' cages, 22,362.
Pneumonic cases specially dangerous and give rise to pneumonic cases, 14,717–9, 14,750.
Pneumonic cases the infectious cases, attendants on other cases not attacked, 9586.
Pneumonia form spreads disease most, 4370.
Pneumonic plague infectious even in hospitals; *cf.* case of Dr. Manser, 1,439, 1,514–6.
Pneumonic plague highly infectious, 10,201.
Pneumonic plague noted for its spread of infection, 11,163.

Pneumonia and Mahamari:

No suspicion in the Hills of the existence of pneumonic plague until the outbreak at Hardwar, 8833, 8955.

PNEUMONIC PLAGUE—*cont.*

Pneumonia and Plague of the Bubonic type:

Bubonic case in one instance gave rise to combined bubonic and pneumonic case, 17,988–9.
Case of bubonic plague may become very infectious if pneumonia sets in, 6918.
Instance of infection of members of a family in Hardwar, one bubonic case followed by three bubonic and two pneumonic cases, 9558–60.
Mixed bubonic and pneumonic case gave rise to two pneumonic cases, 13,179–82.
No instance in which bubonic plague gave rise to pneumonic case, 19,208.
No instances of pneumonic plague from bubonic case or *vice versâ*, 14,123, 14,709, 17,785–7, 17,890, 18,206–7, 18,440, 19,075–6.
Pneumonia developed in bubonic cases, 14,121.
Pneumonic plague contracted from bubonic case, one instance, 16,048.
Pneumonic plague got by contact with bubonic cases, 12,728.
Six instances in which bubonic cases gave rise to pneumonic cases, 15,280.

Pneumonic Cases contracted from Pneumonic Cases:

Four cases of infection from pneumonic cases in Dharwar Hospital, all the persons infected getting pneumonia, and one having a bubo as well, 1891–2.
Four people got pneumonic plague, one after the other in one house, where there was no bubonic case, 15,454–8.
Infection of one type of plague from another type or of pneumonic cases from pneumonic cases not observed, 17,372–5.
Infection of 11 persons from one case of pneumonic plague in Cutch, 530, 13,366.
In one case one pneumonic patient infected ten people with pneumonic plague, in another one pneumonic patient infected two others with pneumonic plague, 18,207–13.
Nurse at Poona contracted pneumonic plague from a patient, 7576.
One case of pneumonic plague gave rise to another in attendant, 7515.
One case of pneumonic plague gave rise to two others, 18,509–10.
Outbreak of pneumonic plague at Backergunge: Details regarding, 6836–43, 7331–407, 7444–75.
Outbreak of pneumonic plague at Backergunge: Dr. Amulaya Charan Bose suffered from pneumonia but not from plague, 7067.
Person who slept in bedclothes of pneumonic patient contracted pneumonic plague, 19,208–35.
Pneumonic cases give rise to pneumonic cases, 14,717–9, 17,788.
Pneumonic cases gave rise to pneumonic cases only, four in one family and two in another, at Kankhal and Jawalapur, 9523–35.
Pneumonic plague: Cases of a laboratory assistant, Dr. Muller, and Nurse Pecha at Vienna, 7220, (17), (22), and (58).
Pneumonic plague contracted by nurse attending Dr. Manser, when he had pneumonic plague, 1439.

Pneumonic Plague communicates Bubonic as well as Pneumonic Plague:

Bubonic case contracted by medical attendance on pneumonic case, 9566.
Bubonic case contracted from bite of pneumonic patient, 4567.
Bubonic plague communicated by inoculation from pneumonic case, 7218.
Bubonic plague from pneumonic cases, two instances, 16,048.
In Gangaur from one case of probable pneumonic plague 37 deaths followed, both bubonic and pneumonic, 13 of the deaths being among the relatives of the first case, 15,182–5.
In one instance a pneumonic case gave rise to both bubonic and pneumonic cases among eight persons, who all died, 17,990–1.
No case of bubonic plague traced to contact with a pneumonic case, 12,729.

PNEUMONIC PLAGUE—*cont.*

No instances of bubonic cases from infection by cases of pneumonic plague or *vice versâ*, 14,123, 14,709, 17,785, 17,890, 18,206–7, 18,440, 19,075–6.
One case of pneumonic plague at Manora gave rise to one bubonic and three pneumonic cases, 12,997–8.
Pneumonic case gave rise to a bubonic case, 13,177.
Pneumonic plague communicates the bubonic form as well as the pneumonic, 1517.
Pneumonic plague, in one instance, gave rise to two bubonic cases, 18,214–6.
Six instances in which pneumonic cases gave rise to bubonic cases, 15,280.

Pneumonic Plague contracted from Bubonic Cases:

No instance in which bubonic plague gave rise to pneumonic case, 19,208.
No instances of pneumonic plague from bubonic case or *vice versâ*, 14,123, 14,709, 17,785–7, 17,890, 18,206–7, 18,440, 19,075–6.
Pneumonic plague contracted from bubonic case, one instance, 16,048.
Pneumonic plague got by contact with bubonic case, 17,728.
Six instances in which bubonic cases gave rise to pneumonic cases, 15,280.

Prevalence of:

Pneumonic cases most frequent in the height of the epidemic, 12,915, 13,104, 18,204.
Pneumonic form of plague not very frequent, 9507.

See Œdema.
,, Lungs.
,, Post-mortem appearances in plague.
,, Sputum.
,, Types of plague in particular epidemics.

PORT REGULATIONS:

Measures adopted and Staff:

Bombay: Evidence on port regulations, I. 34–8.
Bombay: Inspection applied to all crafts, 717.
Bombay: Notwithstanding the heavy work thrown on the Port Health Officers it was carried out in a most thorough manner, III. 363.
Bombay: Number of staff under Port Health Officer at Bombay, 716.
Madras: Procedure on lines of the Venice Convention, 3865.

Measures at Infected Places to prevent the Exportation of Plague:

Bombay: After inspection neither passengers nor crew may go ashore again, 732.
Bombay: All out-going crews and passengers inspected by health officer assisted by staff and two lady doctors, 26,638.
Bombay: Any person suffering from unexplained rise of temperature or from chronic enlarged glands detained, 725–6.
Bombay: Crew and passengers examined on shore if bound out of India, 720.
Bombay: Difficulty in collecting crew long enough before-hand for inspection, 794.
Bombay: Examined for second time on day of sailing, 723.
Bombay: In case person removed from a ship develops plague, telegram is sent to first port of call of ship, 742.
Bombay: Method of inspection, 721, 723.
Calcutta: Passengers and crew inspected on shore. All suspicious articles disinfected, 6455–6.
Cutch Mandvi: People own boats plying to Madagascar, African Coast, and Persian Gulf. These are not examined, and take no bill of health, 13,347, 13,513–5.
Karachi: All emigrants to Mombassa were detained at Kiamari, 11,989.
Karachi: All persons from detention camps sent to the steamers under police escort, 12,225.
Karachi: At one time 2,400 people in detention camp at Kiamari, 11,992.

PORT REGULATIONS—*cont.*

Karachi: Measures applied to out-going passengers, 12,222–25.
Karachi: Rules regarding emigrants, 12,231–3.
See Ships.

Measures at Uninfected Ports to prevent Importation of Plague:

Baluchistan ports: All passengers inspected. No cases seen, 8078–93.
Bombay: Arrangements for keeping under observation persons from infected ports or ships, 772.
Bombay: Inspection of vessels arriving started April 1897, modified April 1898, and applied to infected ports only, 768, 781–93.
Bombay: Medical officer goes on board all ships from infected ports, 784.
Bombay: Quarantine rules for ships coming from Hong Kong and Canton, 775.
Cutch Mandvi: All passengers, without exception, segregated for 20 days at Cutch Mandvi, while plague was very virulent in Bombay, 27,121.
Cutch Mandvi: Precautionary measures against Bombay and Karachi in quarantine camp at, 13,507–12.
Cutch Mandvi: Quarantine for passengers from Bombay and Karachi started in Sept. 1897; very successful, 13,344.
Cutch Mandvi: Stringent measures for passengers from Bombay and Karachi, 27,118.
Karachi: Guarded by harbour boats, 12,318.
Karachi: Native crafts from Bombay kept 10 days, 12,317.
Karachi: Passengers coming by sea from Bombay detained in Kiamari camp, 11,893, 12,151.
Karachi: Quarantine for passengers coming by sea unsuccessful, 4239–50.
Karachi: Quarantine tried for a year, but found too severe a measure and raised opposition, 12,194, 12,527.
Karachi: Regulations for the inspection of passengers arriving in port, 12,139.
Ratnagiri: Quarantine an essential measure as all traffic comes by sea, 20,042.

Measures for Disinfection of Clothing and Personal Effects:

Bombay: Disinfection of crews' kit and clothes by exposure to sun and air, 738, 814.
Bombay: Disinfection of every article taken on board ship impracticable, 811.
Bombay: Kits and baggage of persons free from plague not disinfected as a rule in December 1898, 741.
Bombay: Present rules for disinfection of all kit of crews at pilgrim shed, III. 299.
Calcutta: All suspicious articles disinfected, 6455.
Karachi: Clothing of passengers entering by sea disinfected with Jeyes' fluid, 4243.
Karachi: Clothing of passengers from Bombay not disinfected during first epidemic, 12,989.

Statistics of Results of Measures taken at Ports:

Bombay: List of vessels having left in 1897 and 1898, I. 361–2.
Bombay: Plague cases detected chiefly among native passengers departing for local ports, 749.
Bombay: Table of medical examination of crews and passengers on board ships, 25,479–83, App. X. in Vol. I., and App. LXXV. in Vol. III.
Bombay: Total number of ships examined, 50,177, 771.
Bombay: Very few genuine cases have gone on ships bound from Bombay for foreign ports, 767.
Bombay: 85 per cent. of cases reported as plague from ocean-going vessels recover; 85 per cent. of plague cases in Bombay die, 726.
Bombay: 149 plague cases among outgoing passengers detained discovered by inspection at Bombay, 747.
Bombay: 16,798 people detained at Bombay, 746.

PORT REGULATIONS—*cont.*

Bombay: 43,477 incoming passengers detained in observation camps, 48 cases of plague, 771–2.
Bombay: 87,571 crafts inspected at Bombay from January 1st to November 30th, 1898, 745.
Cutch Mandvi: 15,988 passengers examined from October 1897 to July 1898. Twenty-two cases sent to plague hospital, 27,122.
Karachi: Details of plague cases in detention camp, 12,982.
Karachi: In 1897 nine cases of plague was imported by sea, and in 1898 seven cases, 12,995–6.
Karachi: Of 35,360 passengers detained in camp five had plague, 12,161–2.
Karachi: Only one mild case of plague among 69,366 passengers and crew on board of vessels between August 1st, 1897, and December 1st, 1898, 12,145
Karachi: Seven cases of plague detected among in-coming passengers at Kiamari, 11,998.
Karachi: 7,310 people leaving by sea detained in April, May, and June, 12,237.
Karachi: 35,360 incoming passengers detained in detention camp from August 1st, 1897, to December 31, 1898, at Kiamari, 11,987.

See Bombay: *Introduction of plague into:*
,, Ships.

POST MORTEMS:

Done in all suspicious cases at Hubli for about three months in 1898, 3077–8, 20,007.
Objected to in India, 4615, 10,343, 19,531.

See Corpse Inspection.

POST-MORTEM APPEARANCES IN PLAGUE:

In Animals:

Greater variety in organs of guinea-pigs than in those of rats, 26,409.
Pathological appearances in animals experimented upon with plague, 26,407.
Post-mortem appearances the same in animals partially protected by inoculation with plague virus and those dying without previous inoculation, 27,363.

In Plague Patients:

Appearance of the several organs, III. 44.
Notes on 54 autopsies in Arthur Road Hospital, 20,972.
Post-mortem appearances of cases of bubonic plague, II. 65.
Post-mortem appearances of cases of internal bubo with hæmorrhages, II. 64*ab*.
Post-mortem appearances of cases of typical plague pneumonia, 6913.
Post-mortem appearances of pneumonic plague, 1418–33, I. 368–9.
Post-mortem appearances of septicæmic case, I. 439–40.
Post-mortem appearances of the septicæmic variety of plague, II. 64*b*.
Post-mortem of intestinal plague in which the mesenteric glands were found much enlarged, 9371.
Special appearance of septicæmic form after death, 21,365.
Summary of post-mortem examination of the different organs, 1419–26.

Post-mortem appearance:

Hæmorrhages: Description of internal hæmorrhages, 8898.
Hæmorrhage in every part of the body, 20,972.
Hæmorrhages: Small hæmorrhages in Peyer's patches seen in two cases, 6899.
Of alimentary system, I. 367.
Of brain: Engorgement of the vessels, but no softening or actual hæmorrhage, 1421.
Of genital system after death from plague, I. 368.
Of heart: Soft and flabby, 1421.
Of kidneys, 1421.
Of kidneys: Only in two case of post mortem kidneys found to be affected, 9622.

POST-MORTEM APPEARANCES IN PLAGUE—*cont.*

Of kidneys: Sometimes petechiæ on the capsule of the kidneys in bubonic plague, 10,421.
Of liver, I. 367.
Of nervous system in the bubonic form, I. 367.
Of peritoneum, I. 368.
Of spleen, I. 367.
Of urinary system, I. 367.
Petechiæ always found post mortem, 1420.
Petechiæ not seen on the skin, frequently on internal viscera, 9572.
Petechiæ of the stomach a noticeable feature in post mortems after bubonic plague, 10,419.
Petechiæ sometimes on the capsule of the kidneys in bubonic plague, 10,421.

See Blood.

PRECAUTIONARY MEASURES.

See Measures, Plague.

PRECAUTIONS, SANITARY.

See Measures, Plague.

PREGNANCY:

Abortion in a plague patient a short time before death, 12,987.
Pregnancy and miscarriage, prognosis bad, 15,308, 16,544.
Pregnant patients generally aborted on the first or second day of attack, I. 380.
Pregnant women miscarry when attacked by plague, 23,733.
Premature confinement, supposed due to plague, 12,818.
Recoveries rare in pregnant women, 20,864.
Woman died after confinement, but child was not attacked, 1451.

See Inoculation with Haffkine's plague prophylactic: *After effects* and *Bars to inoculation.*

PREPARATION AND CHARACTER OF HAFFKINE'S PLAGUE PROPHYLACTIC.

See Haffkine's plague prophylactic.

PROGNOSIS IN PLAGUE CASES:

Bad:

Aphasia, 13,030.
Buboes: Cases with small buboes generally fatal, 21,652.
Coma, 12,413.
Diarrhœa generally just before death, 20,850.
Exudation, rapidity of, 20,725.
Hæmorrhage, 12,413.
Lung symptoms, 19,078.
Petechiæ, I. 352.
Pregnancy and miscarriage, 15,308, 16,544.
Pregnant women rarely recover, 20,864.
Presence of bacilli in the blood, 17,402, 20,805.
Pulse intermittent, dicrotic, weak and irregular, 12,413.

Good:

Bubo, suppuration of, 1529.
Bullæ after the acute stage favourable, 16,816.
Disappearance of bacilli from the blood, 20,807.
Favourable and unfavourable symptoms, I. 382.
Gland if confined to the femoral region, 13,025, 15,308, 16,544.
Nervous symptoms, doubtful, 12,413.
Pulse and speech improvement, 15,310.
Survive the first five days, patients if, 12,415.
Urea and uric acid, free excretion, 20,860.

Children:

Better prognosis among children than among grown-up people, I. 352.

See Temperature.

PROPHYLACTIC, HAFFKINE'S.

See Haffkine's plague prophylactic.
,, Inoculation with Haffkine's plague prophylactic.

PROSTITUTES:

General belief that prostitutes under syphilis are immune from plague, 917, 8693, III. 43.

PULSE:

Clinical Feature of Plague:

Character of pulse in plague, I. 380.
Pulse feeble and dicrotic, but of varying character in different patients and different stages of an illness, 20,800.
Pulse similar to that of aortic regurgitation, 21,035.
Pulse small, easily compressible, and frequent, 12,398.
Sphygmographic charts of patients treated in the Arthur Road Hospital, Bombay, III. 547.

Prognosis:

Improvement in pulse good prognosis, 15,310.
Pulse intermittent, dicrotic, weak, irregular, 12,413.

QUARANTINE:

Baroda: Not successful in keeping plague out, 15,378.
Bhuj: A 15 days' quarantine maintained through the whole time of the epidemic, 13,407.
Bhuj: Plague kept out by the strict quarantine, 13,544.
Bulsar: Strict quarantine kept out plague for a long time, 24,447.
Cutch: Quarantine arrangements started in September 1897; very successful, 13,344.
Cutch: Ten days' quarantine for passengers coming by the land route, 13,344.
Karachi: Quarantine tried for a year but found too severe a measure, 12,194.
Satara: Quarantine, rules at, 22,262.
Villages: Difficulty of keeping relations of influential people out from infected villages, 22,993.
Villages: People learn to guard themselves against reintroduction of the disease by keeping outsiders away, 10,976.
Villagers quarantine strangers of their own accord, 3954.

Opinions regarding:

Quarantine a most essential precautionary measure, 20,042.
Quarantine an important measure, 22,380.
Quarantine cannot stop plague unless it can be extended to rats and other animals, 22,446.

See Port Regulations.

RABBITS:

Haffkine's plague prophylactic, effects studied in rabbits, 28–9.
Haffkine's plague prophylactic requires to be injected in very large doses into rabbits to afford protection, 5201–4, 5685.
Experiments in the Hyderabad State on rabbits for the identification of the plague bacillus in earth and in order to test the effects and sterility of Haffkine's prophylactic, 5164–78, 5215–92, 5293–414, 5590–1, 5713–7, 5744–79, 5915–25, 24,588–820, 24,917–21, 24,932–3, Vol. I. App. XVIII; Vol. III. Apps. LXIX. and LXX.
Experiments in the Hyderabad State on rabbits to test the presence of plague infection in raw cotton, 24,580–7, 24,820–94, 24,922–5, 25,903–9, Vol. III. App. LXVIII.
Presence of plague infected in houses tested in the Hyderabad State by inoculation of earth from the houses under the skins of rabbits, 5670–3.
Rabbits relatively resistant to plague, 8585.

RACE AS AFFECTING LIABILITY TO PLAGUE:

African: No African suffered from plague in Calcutta though many, and poor, 6970.
Bangalore: Statistics of plague according to race, I. 109, 25,015.
Bombay hospitals: Mortality from plague by race, I. 391.

RACE AS AFFECTING LIABILITY TO PLAGUE—*cont.*

Burmese and Chinese seem to possess some kind of immunity from plague, 6863.
Chinese: Not a single case of plague among Chinese or Japanese at Bombay during the three epidemics, III. 43.
Chinese: Only one Chinaman dies at Calcutta, 6862.
Chinese wear boots in Calcutta, 6863.
Distribution of plague cases among nationalities, 7073.
Influence of race on plague, 17,681–86, 22,264–7.
Japanese: Not a single case of plague among Japanese at Bombay during the three epidemics, III. 43.

See Inoculation with Haffkine's plague prophylactic.

RAILWAY MEASURES:

Adopted in:

Ahmednagar: Excellent railway precautions in, 24,217.
Bangalore: Adopted at, 3442.
Bombay: Commenced early in November 1896, I. 52.
Bombay: Statement of measures for the protection against plague at the several stations of the railways, I. 53–4.
Poona: System of railway precautions, 21,769.
Surat: Railway precautions, 15,539.
Variations in the plague regulations of railway stations most inconvenient to travellers, 21,616.

Detention and Observation Camps:

Ahmedabad: On November 3, 1897, observation camp established at, 13,891.
Anand: Detention camp opened on November 24th, 1897, and closed May 17th, 1898, arrangements in, 14,106–57, 14,165–93.
Bandra: Camps for observation of people leaving Bombay; each family had a separate hut, and castes were kept together: no spread of plague in camp, 8236–43.
Bengal: Detention at Khana till 10 days complete after leaving infected place, 6711–2.
Bombay: Detention camps employed till middle of 1898. New rules then instituted, including medical examination, disinfection, inquiry as to destination, and detention of suspicious persons, 1285.
Bhusawal: Observation and plague camps erected for the protection of Calcutta, the Central Provinces, and Bengal, I. 52.
Dharwar: Observation for people from infected localities, 1927.
Hubli: Ten days detention for all arrivals in, 2429.
Hyderabad State: Strict detention on railway and patrols on the roads leading from infected villages have kept plague from the city, 29,916.
Kaira district: Precautionary measures at the railway stations, 14,018.
Kotri: Only railway passengers with high temperature detained at, 12,666.
Malir: Camp for observation of people leaving Karachi; arrangements, 4256–62, 12,440–5, 12,498.
Malir: Ten days strict detention in Malir segregation camp, 12,495.
Rajputana: Detention at first for 10, then for five days, 9729–34.
Rajputana: Interpretation of the word "suspicious" by the Government of India and the Native States, with regard to detention on railways, 9786.
Rohri: Passengers from Karachi and intermediate stations detained at, 12,065.
Sibi: All passengers detained for not more than 10 days on coming into Baluchistan, 8086–91.
Surat: Passengers for, detained or kept under surveillance, 2062.
Tungabhadra: Detention for 10 days of suspicious passengers, 4490–515.

Detention Camps, Efficacy of:

Detention, if efficiently carried out, prevents the importation of plague beyond the camp, 14,189.

RAILWAY MEASURES—*cont.*

Observation camps and inspecting stations best means for keeping out the plague, 9728–9.

Detention Camps, Plague Cases in:

Bandra: Twenty cases discovered in passengers from Bombay, 8238.
Bengal: Six cases of plague detected, 6712–9.
Bombay detention camps: Number of plague cases in, 1291, 26,537.
Dadu: Twenty-seven cases taken out of trains developed plague, 12,672.
Malir: Few cases of plague out of thousands examined, 4263–5.
Malir camp: 108 cases of plague among the travellers by rail from Karachi, 12,430.
Poona: Twenty-three cases among 13,606 passes, 21,539.
Rajputana: 38 plague cases, 9729.
Rohri: One case developed in 266 detenus, 12,065, 12,072, 12,097, 12,100.
Sibi: One plague case in detention camp, 8092.
Tungabhadra: No plague case, 4510, 4516.

Detention Camps, Mortality in:

Table showing number of deaths among detained in Anand camp from causes other than plague, 14,187.

Detention Camps, Number in:

From 5,000 to 6,000 people in Anand detention camp at one time, 14,176.
From end of November 1897 to end of May 1898, about 58,000 people detained in camp at Anand, 14,177.
Hyderabad State: Number of passengers examined and detained by railway inspection from February 1897, 5789, 25,912.
Seven thousand nine hundred and twenty-five persons detained in Malir camp during April, May, and June, 12,429.

Detention Camps, attitude of the People towards:

Objection to detention camps on railways, but not to examination; attempts at evasion, 1298.
Objection to Malir camp on account of it interfering with trade, 12,528.
People object to detention and try to evade it, 1298.

Disinfection on Railways:

Bombay: Disinfection of railway baggage, 1285.
Disinfection at frontier stations only of third-class passengers who look dirty, 1285, 1312.
Goods trains: No disinfection of goods trains, 7298.
Infected carriage either disinfected at once or locked up till it can be, 1334.
Khana Junction: Method of disinfection adopted at, perfect but no proper supervision, hence clothes, &c. passed through without disinfection, 7494, 7497.

See Persons.
,, Clothes.

Medical Examination on Railways:

Believed to have prevented infection by railway into Calcutta, 6887.
Deterrent effect on travelling of plague cases or people who are probably infected, 1297.
Examination keeps away many who are sickening, 824.
If medical examination were taken off, the country would be flooded with plague cases immediately, 26,544.
Medical examination acts twofold; it discovers cases which go out, and prevents a great number from leaving, 26,538.
Railway inspection first line of defence against introduction of plague in a town, 21,767.
Stopping suspicious cases as efficacious as old system of stopping all passengers, 1302.
Train inspection a most salutary measure, 8753.
Under the precautions of careful medical examinations the exodus of the population from an infected town offers but slight risk, 26,537.

RAILWAY MEASURES—*cont.*

Value of railway examination, 26,537.
Value of railway inspections small, 4355.

Medical Examination, on Railways; arrangements for:

Ahmedabad: Railway inspection of passengers from Bombay commenced on October 5th, 1896, 77 cases detected to February 16th, 1897, 13,869, 13,886.
Anand: System of medical inspection of railway passengers, 14,107–8.
Baluchistan: Two cases detected by examination, 8092.
Bangalore: Medical examination of passengers leaving, and regulation forbidding departure without pass, 2586.
Bombay: Results of medical examination to middle of March 1898, 26,537.
Bombay: Results of railway inspection on the routes to, 1291.
Bombay: 221 posts of inspection gradually established at the principal stations and junctions, III. 363.
Calcutta: 41,854 people detained and six probable cases of plague resulted, 6715.
Central Provinces: About 20 plague cases stopped by examination by December 1898, 5952–6.
Female passengers examined by lady nurses, 12,865.
Guntakal: Inspection, I. 185–6.
Guntakal: 69,050 examined, 32 detained, one developed plague, 4500–2.
Guntakal: 111 suspicious cases removed from train, four developed plague, 5130–1, 5140.
Karachi and Malir: In first Karachi epidemic no cases detected, but 13 detected at Malir in second epidemic, 4256–66, 12,425–45.
N.W.P.: Two plague cases detected, 8753.
Occupants of infected carriage, if in good health, not detained, 1337.
Poona: Examination at first not strict, 12,863.
Poona: Forty cases detected in 1896–7, 12,850–3.
Poona: Medical examination of passengers departing in 1896, 2393–6.
Results of examinations at various railway junctions, I. 53–4.
Surat: Nineteen passengers detained, of whom 11 developed plague, 15,554–7, 15,871.
Table of results of medical examinations at certain stations for varying periods, I. 55.
Temperature made test for detention. Anyone over normal detained for 24 hours' observation, 1286–8, 1301.
Tungabhadra: 31,272 inspected, no plague cases, 4508–16.
Wardha district: Several hundred detained, about 20 cases, 5951–5.

RAINS:

Bangalore: Plague measures stopped on account of the rains, 2551.
Bengal districts: Rainfall is deficient during early months of 1898, 6874.
Bombay: Abnormal monsoon before outbreak in, 892.
Bombay: Heavy rainfall, increasing dampness of and rise of sub-soil water level preceded the present epidemic in, 25,268.
Cutch Mandvi: Epidemic influenced by damp weather and heavy dews, 13,485.
Germs become less virulent after rains, 22,356.
Hubli: Rains interfered with the work of plague staff, 1589.
Kolaba: Epidemic ceased during rains in, 17,650.
Kotri: Heavy rains and inundations before second outbreak, 12,593.
Rains assist spread of infection at Hubli, 2.
Rains assist spread of infection round Poona in 1897, 2.
Rains make preventive measures almost impossible, 2.
Rains make supervision and evacuation impossible, 1588–9.
Rains prevented plague measures in Bhiwandi, 22,176.
See Evacuation: *The rains and their effect on evacuation.*

RATS:

Arranged under the following subheads:

Bacillus of Plague, discovery of:
in bodies of dead rats.
in the blood of rats.
in the fæces of rats.
in the spleen of rats.
in the urine of rats.
Death of rats:
Before an outbreak of plague among men.
During and after Outbreak among Men.
Not followed by Plague among Men.
Not noticeable in connexion with Plague among Men.
Regarded as a warning of Plague and action taken upon..
Destruction and disappearance of rats.
Infection of Plague communicated and spread by rats.
Liability of rats to Plague.
Manner in which rats contract Plague.
Movements of Plague-infected rats.
Post-mortem Appearances.
Opinions regarding influence of rats in spreading plague:
Opinions that rats important Agents in spreading plague.
Opinions that rats not important Agents in spreading plague.

Bacillus of Plague, discovery of:

in bodies of dead rats:

Bacillus discovered in dead rats at Bangalore, 3592.
Bacillus found in dead rats at Bombay, 8705.
Bacillus found in dead rats at Hubli, 3117.
Bacillus of plague not found in mummified rats or any other material from the infected houses in the Joria Bazar at Karachi, 11,210.
None found in dead rats, gunny bags, or any material from the infected houses in the Joria Bazar at Karachi, 11,210.
Not found in supposed infected rats, 635.

in the blood of rats:

Invariably found in the blood of dead rats, if examined at once, 17,499.
None found in the blood of rats, 17,248.
None found in the blood of rats inoculated with earth from plague-infected rooms, 26,157.
Microbe disappears very quickly from the blood of dead rats, 17,500.

in the fæces of rats:

Found in the intestinal contents, 8602.
Not found in the excreta, 17,248, 17,410.
Reported as found by the German Plague Commission in the dung, 994.

in the spleen of rats:

Culture from the spleen of a dead rat gave typical plague bacilli, 10,235.

in the urine of rats:

Found in the urine, 17,248, 17,410.
Not found in the urine, 8602, 17,505.
Reported as found by the German Plague Commission in the urine, 994.

Death of rats:

Before an outbreak of plague among men:

Ahmednagar: Rats found dying before outbreak in 1898, 24,276.
Alibag: Many die before recrudescence of plague, 17,619.
Balutji: Die seven or ten days before first plague case, 5518.
Bangalore Lunatic Asylum: Discovered just before outbreak, 3510.
Baroda, Dave Muhalla: Rats died on importation of infected clothes, and persons died after, 15,170.
Baroda: Seen dying near spot where plague first broke out, 15,347.
Belgaum Jail: Dead rats found before outbreak of plague in which seven cases occurred in seven days, 22,870, 22,924-5, 23,047, 23,073.
Bombay: Dead rats found in godowns containing Chinese goods at Mandvi a fortnight before cases of plague occurred, 17,772.

Rats—*cont.*

Bombay: Death precedes outbreak among people, 1002, 1168, 8288, 10,961.
Bombay: First cases in August, rats die in September, 1176.
Bombay: Malabar Hill: Death of rats usually precedes outbreak of plague, 1375-7.
Bombay: Mandvi Ward: Die in large numbers where plague breaks out, 601.
Bombay: No striking mortality among, before epidemic, 997.
Bulsar: Found dead a week before outbreak among Dhebras, 16,164.
Calcutta: Dead rats preceded plague in seven out of 32 cases inquired into, 7188.
Calcutta: Rats die before human beings in certain houses in, 6451, 7187-8.
Calcutta: Human cases occur where dead rats had been previously found, I. 467.
Calcutta: Found dead before 1898 plague cases, I. 464.
Calcutta: Heavy mortality in March 1898 7503.
Calcutta: Epidemic among, 10 days before first reported case, 6468.
Calcutta: Sickness and death from plague were associated with unusual mortality among rats in houses affected, 7184.
Dead rats found near grain mart before epidemic, 3242.
Dead rats found in two houses 10 days before people were attacked, 10,454.
Death of rats usually, but not always, precedes plague, 25,218-20.
Death of rats precedes plague, as they spread the disease, 25,794.
Die in houses just before outbreak of plague, 1
Die before inmates in infected houses, 3425.
Found dead between an imported and indigenous case, 15,199.
Ghoti: Dead rats found in several parts before plague was discovered among human beings, 14,695.
Guntakal: After the first case rats died and probably spread the infection to the later cases, 5048-62.
Hale Tegur, and Mandihal: Plague followed infection of the rats, 23,558-9.
Hinganghat: Die in houses before outbreak, 6200.
Hyderabad State: Rats generally die before plague breaks out, 5854.
Hyderabad: Great mortality among rats between the imported cases and the first local case, 18,106.
Kankhal: Mortality among rats observed before the epidemic, 8774, 9074.
Karachi: Found dead in large numbers before second outbreak, 3785-90, I. 29.
Karachi: Great mortality among rats, on second outbreak rats beginning to die a week or two before first human case, 11,198-205.
Karachi: Kiamari: Plague cases appeared in the Customs lines soon after some dead rats had been found in the lines, 11,976.
Karachi: Mortality among rats precedes plague cases in houses, 11,313, 11,835-7, 11,974, 22,646.
Khandwa: Rats died on importation of infection, and a human case occurred later, 5958-61.
Kotala: Deaths before outbreak of plague, 4167, 5097.
Kotur: Rats died before spread of plague and spread was due to them, 23,612-25.
Ladghar: Rats died on importation of infected clothes, and men died afterwards, 20,066-73.
Local infection among human beings occurs generally three days after rats begin to die, 23,563.
Mortality in rats in individual houses preceding mortality among human beings in those houses, 18,005.
Mortality among rats invariably precedes that among men, 8906, 19,650-3.
Mortality among rats in 22 villages preceded outbreak of plague by an average of three days, 23,563.

RATS—*cont.*

Mortality in rats usually precedes human cases by about eight days, I. 464.
Mundra: Before plague became epidemic many dead rats found, 13,401.
Nasik: Dead rats found three days before indigenous cases, 14,705.
Rats seen in a dying condition in a house in Sotran where plague broke out five days later, 10,082.
Sukkur: Affected before outbreak, 290.
Vinzol: Discovery of dead rats followed after a fortnight by plague cases, 14,073.

During and after Outbreak among Men:

Ankleshwar: Several monkeys, rats, and squirrels died of plague, 14,243.
Bangalore: Great mortality after outbreak of plague, 2653.
Bantwa: Many found, particularly in a house with 16 cases, some of which occurred after disinfection, 17,565, 17,589, 17,595.
Baroda: Rats died in, 14,641.
Belgaum: No case in any village in which rats not also affected, 22,898.
Bhiwandi: Many rats and squirrels were found having died of plague. 14,493, 22,124–6.
Bombay: Mandvi: Rats died in large numbers when plague increased in virulence, 8704, 14,437, 19,159.
Die at same time as and after human beings, 7184. After, 7185.
Garshankar: Die in infected houses; not found while disinfection going on, 10,743.
Guntakal: Die in large numbers but not before first plague cases, 4139, 4169, 4171, 4177.
Hubli: Dead rats found in great numbers under the floor of a goods shed, 3117.
Hubli: Dead rats discovered in chawls and town after epidemic had begun, 2442.
Hubli: Hundreds dead in goods shed, 3117.
Jamalapur and Kankhal: Death of rats, 9189.
Karachi: Dead rats very numerous, 11,198–205, 22,646–7.
Kiamari: Rats found in numbers in the railway godowns during plague, 11,974.
Poona: Dead rats in 1899, 21,503, 25,831.
Satara: Dead rats found, 22,530, 22,681.
Sholapar: Dead rats found in every infected village, 24,048.
Sukkur: Heavy mortality at time of plague, 2269–73.
Timmencherla: Death of, in plague-infected houses, 5047, 5051.
Umreth town: Many dead rats found in villages during the epidemic, 14,076.

Not followed by Plague among Men:

Bombay: Dead rats found on ground floors and upper storeys of well-ventilated houses without the subsequent occurrence of plague among men, 25,220.
Bombay: Malabar Hill: Death of rats in a good house not followed by plague, 1447.
Bombay: Sherli village: An epidemic among rats in a village where no cases occurred among human beings, 18,966.
Daman Fort: Many found dead, no case among men supervening, 15,960, 16,449.
Doongri: Rats died without plague among men, 14,377.
Hyderabad State: In several cases rats died in villages where plague did not follow, 5854.
Poona: Death of rats in good houses not followed by plague, 21,538.

Not noticeable in connexion with Plague among Men:

Little evidence of rats mortality in Panjab in the autumn of 1897, but rats died everywhere next spring, 10,127.
Mortality among rats not an incident of plague at Nasik, 13,819, 16,962–4, 16,998, 24,512–4.
No dead rats at Ahmedabad, 13,929.
No dead rats at Rohri, 12,057.
No dead rats in first Belgaum epidemic, 23,068–72.
No dead rats in certain Dharwar villages where infection not so general as elsewhere, 23,571, 23,578.

RATS—*cont.*

No great rat mortality in Ahmednagar, 24,090–1, 24,241, 24,276, 24,332.
No great rat mortality noted in Surat, 15,887, 16,062.
No mortality of, observed at Karachi, before first outbreak, 11,098, 11,201, 11,202.
No mortality among rats or other animals at Khandraoni, 9675.
No mortality among rats in Kajurgi, where 22 plague cases occurred, 5504–6.
No rats died at Hardwar, 8913, 9448.
None found at Chipagiri; none at Molagavelli, 4411, 4445, 5011.
Not affected in Cutch during epidemic, 13,461.
Not affected in civil station at Karachi, where there was no plague, 11,345–52
Rat mortality not noticeable at Poona to February 1899, 7567, 10,923, 21,723.
Rat mortality not noticeable at Sholapur, 23,953.
Very few dead rats in Cutch Mandvi, 13,461, II. 480.
Very few rats in Nagar town during epidemic, 18,992.
Very few dead rats in Palanpur, 13,153–5.

Regarded as a warning of Plague and action taken upon:

Evacuation of village on appearance of dead rats and subsequent plague among the people probably contracted by visits to the evacuated houses, 23,215–24.
Good effects of evacuating villages in Dharwar on appearance of dead rats, 23,583–4.
Hamirpur: Evacuated on death of rats, no outbreak, 10,400–4.
Inhabitants of one village leave because of dead rats; no plague cases, 2116.
In the Broach district the health inspectors are required to report the discovery of dead rats even before the appearance of plague, 14,432.
Nasik: Dead rats cause evacuation of village, 9.
Only houses were evacuated in which plague cases occurred or dead rats were found in fort in Bombay among the Parsees, 25,247.
Palanpur State: Villages evacuated on appearance of dead rats. Plague appeared among the people of these villages after evacuation, 13,146–52.
Voluntary evacuation of Lasundra and Bahutha as soon as rats were found dying in the villages, 14,664.
Voluntary evacuation in N.W. Provinces following an outbreak of epidemic among rats, 8839.
Wasind evacuated on appearance of dead rats, and epidemic stopped, 19,654.

Destruction and disappearance of Rats:

Abnormal increase in number in Bombay in 1896, much damage to grain, 892.
Ahmednagar: Rats entirely disappeared after disinfection and evacuation, 24,330.
Bombay: Rats practically exterminated in the locality of the docks since 1896, 19,247, 19,329.
Half-anna paid for destruction; 50,400 paid for in 1898, 1367.
Khandraoni: Rats disappeared from the villages after plague, 9904.
Lascar's microbe killed white mice but not black rats in laboratory experiments, III. 324.
Marwaris object to their slaughter, I. 464.
Poisoning of, approved, 10,975, 16,251.
Poona: Reported all to have died, 7563.
See Habits of the people.

Infection of Plague communicated and spread by Rats:

Areh: Plague in village in houses in which dead rats found, 22,223.
Bandra District: Plague spread from village to village by rats and occurred on occupation of houses infected by rats, 23,207, 23,210.
Banga: Found infected, and infect the village, 10,235.

RATS—*cont.*

Bangalore: Only European who had plague had many dead rats and squirrels in his house, 2600.
Bhaynder: Infected by rats from Utan, 5 miles distant, 14,377.
Bhiwandi: Shop full of dead rats the centre of infection, 22,125.
Bite of diseased rat communicated plague, 1181.
Bombay: After dead rats found in a house, every one vacated it except one person, who remained, and 10 days after got plague, 1180.
Bombay: Dukar Gali: Plague in a boy after handling plague rat, 17,996.
Bombay: Granaries at Mandvi attracting the rats, the source of infection is continually renewed, 17,837.
Bombay: In a house in the Fort, on rats dying, and no precautions being taken, the servants and some of the European residents got plague, 20,416.
Bombay: Infected by sick rats from Hong Kong, 19,189.
Bombay: Malabar Hill: Instance of plague cases by sleeping in room where dead rats had 10 or 12 days previously been found, 18,190, 18,196.
Bombay: Rats probably spread disease all over Mazagaon and Byculla, 25,794.
Boys who killed rats in Mandvi fell ill, 997.
Case of individual contamination by dead rats, 11,418.
Children who eat dead rats in Kumaun not affected, II. 334.
Convey infection in an evacuated village, 10,141.
Coolies who cleared out dead rats from Bombay go-downs were not affected, 19,437–41.
Direct communication of plague to persons handling dead rats, 19,021.
Diseased rats taint articles with dung or urine, 992.
Evidence of infection being transmitted by, 10,109–18.
Excreta of rats supposed to cause infection, 15,459.
Fairlie Place: Mortality co-incident in one house with attack of nine workmen, 7182.
Hardwar and Kankhal: The epidemic among rats the connecting link between the outbreak, 8775, 8913.
Holihosur: People out for a month without plague; on their return plague occurred, rats having died in the village, 22,943.
Hunsikatti: Plague apparently spread by rats through the village while evacuated, 23,215–24.
Infection from infected rats through insects to human beings, III. 44.
Karachi: Plague brought by rats, 12,984.
Karachi: Rapid spread of disease through the voluntary evacuations and diffusion of rats in, 11,413.
Karachi: Three people got plague in house in which shortly before rats died, 11,421.
Karad: Plague in postmaster's house after rats died, 14,363.
Man removed dead rat and burnt it, and got plague after, 20,418.
Panjab: Banga: plague probably spread by rats, 10,235, 10,256.
Panjab: Chak Kalal: Plague on premature occupation of houses infected by rats, 10,109–10, 10,189, 10,603.
Panjab: Hamerowal, alleged to have been infected by rats, 10,113, 10,400.
Panjab: Mahlgahla: Plague on occupation of houses infected by rats, 9987, 10,348.
Panjab: Punian: Rats the source of infection, 10,077, 10,401–4.
Panjab: Rats appear to have spread the plague in several villages, 10,152.
Panjab: Rats probable agents of spread in Lidhar Kalan, Bika, and Garkshankar, 10,454, 10,456, 10,844–54.
Parli: Rats took plague from house to house, 19,647.
Plague case follows on a dog laying a dead rat on bed, I. 474.

RATS—*cont.*

Plague case follows on dead rat being trodden on, 16,513.
Poona Cantonment: Rats supposed to carry infection, but not very numerous, 10,923.
Poona: Cases in 1899 after rats died, 25,831.
Sirohi State: Rats probable source of infection in the, 9722, 9785, 9904.
Spread the plague by contaminating houses, 11,415.
Suspected of causing outbreak in Calcutta in 1898, 7118–23.
Thana: Two men sent to clean a house where dead rats had been found got plague and died, 220.
Three persons in one house got plague, one after the other, from sleeping on the only part of the floor attacked by rats, 23,598.
Umbowda Budruk: Plague follows on death of rats in a house, 22,223.
Woman contracted plague by throwing out dead rat and scrubbing with her hands the place where it was found, 17,926.

Liability of Rats to Plague:

Bombay rats frequently found immune, 26,311.
Rats observed in all parts of Mandvi running about as if drunk, 19,437.
Squirrels seem to die off more quickly than rats during the epidemic, 3120.

Manner in which Rats contract Plague:

Apparently not infected by other rats suffering from plague, 696.
Appearance of lungs in rats dead of plague suggest infection by inhalation, 17,247.
Calcutta: Instance showing that rats may have contracted the disease by gnawing body of a man dead of plague, 7185.
Contract infection before men owing to their connexion with soil, 17,366.
Damaged grain source of contagion to rats thence to men, III. 42.
Eat with impunity supposed infected bags, and artificially infected grain and bags, 635–42.
No data to prove that rats contract the disease from one another, 8906.
Somewhat doubtful whether rats affected through mucous membrane of the respiratory passages, 8703, 26,311.
Take infection from rat-case in Bombay laboratory, 17,498.
Very virulent plague would infect rats if fed with it, 8691, 8733.

Movements of Plague-infected Rats:

Dead rats found in Belgaum in the huts to which evicted people moved, 23,071.
Dead rats found in houses at Surat that had been closed for months, 2042.
Definite proof that rats carried infection along a distance of 600 yards, 22,262, 22,281, 22,437.
Evidence in favour of infection being carried by rats from one part of an evacuated village to another, 22,065–72.
Instance in which plague followed on the appearance of rats in one village and not in another, 14,377.
Instance in which plague was carried by rats to a considerable distance, 14,363.
Instance in which rats carried plague one mile, 23,215.
Kalindri: Plague carried by rats to a well outside the village, 9718–24, 9784–7, 9859–61.
Migrate from infected area to distance of two miles, 17,566.
Migrate on the occurrence of the disease, 1244.
Movements across Bombay from grain stores bring plague, rats moving in advance of and spreading the disease, 998, 1168, 1260–1, 8277, 8288.
No evidence obtained in Panjab that rats migrate in numbers from plague villages, 10,107.
No migration of rats observed in the villages near Baroda, 14,645.
Observed migrating over the causeways from Bombay, 19,237.

RATS—*cont.*

Opinion on observations in Dharwar that rats never move out of a village, 23,596.
Rats carried plague from Dharwar to a village ½ mile away, 2116–20.
Rats followed villagers into camp and from one camp to another in two villages in Satara, 23,012.
Rats found in a health camp just outside a village in the Panjab, 10,120.
Rats migrated ¾ mile to Bhagda from Bulsar and took plague, 16,190.
Rats present, found alive and not dead, in Arthur Road Hospital, Bombay, which they have not left on account of plague, 21,008–10.
Rats seen to go from house to house in Karachi, 22,646–7.
Sirohi State: Rats migrated from village to village carrying plague, 9784,
Some having died, others leave house, 16,473.

Post-mortem Appearances:

Greater variety in those of guinea-pigs than in those of rats, 26,409.
Pathological appearances in rats experimented upon with plague, 26,407.

Opinions regarding influence of rats in spreading plague:

Opinions that Rats important Agents in spreading Plague:

Animals do not seem to spread plague except, perhaps, rats, I. 378.
Danger of infection through clothes much less than through bags containing grain, in which rats would nestle, 994.
Disinfection of houses in India useless, as they are infested with rats which keep up the infection, 11,460–2.
General belief of epidemologists that rats are the principal carriers of infection, I. 464.
Infection chiefly spread by rats, 998.
Infection conveyed by rats, 17,251, 25,794.
Karachi: The wretched condition of the houses in the market quarter and their insanitary conditions enabled rats to spread the disease, 22,649.
Karachi Disease spreads very rapidly in the market quarter because plague broke out there and was assisted by unsanitary condition and also spread by the rats in the granaries of that quarter, 22,645–6.
Karachi: Rapid spread of disease through the diffusion of rats in, 11,413.
Little doubt that rats carry infection after it has been introduced by human agency, 22,693.
Mandvi, Bombay City: The granaries attracting the rats, the course of infection is continually renewed, 17,837.
Opinion that imported cases do not give rise to epidemics unless the rats are affected (Cutch Mandvi) II., 477 (*k*) (3).
Plague spreads by proximity through the agency of rats, 10,456.
Plague spreads by the agency of rats, but it also seems to travel of itself, as there are very few rats in some villages attacked, 22,618.
Poona: Undoubted infection by rats, though a localised one, 25,831.
Rats an important agency, 22,064–6.
Rats chiefly carry the plague from house to house in villages, 22,618.
Rats have much to do with spread; in two villages died 15 to 20 days before local cases, 17,779.
Rats more important agents in spread than men, 17,925.
Rats important agency; spread plague near grain market in Bangalore. 3229, 3240.
Rats chiefly, and also infected persons, spread plague, 3361.
Rats, infected before man, spread the disease, 14,072–8, 15,199, 18,107, 18,792–5, 19,650, 22,922, 24,044.
Rats and grain somehow responsible for infection, 8277.
Rats, clothing, and some unknown agent in the retail grain shops spread plague, 11,278.

RATS—*cont.*

Rats must convey contagion, for they are always found where plague is found, 17,891.
Rats play an important part in the propagation of the epidemic, 11,835.
Rats the most powerful source of infection, 19,028.
Result of experiments to determine the importance of rats in the spread of the epidemic, III. 324.
Spread infection where helped by insanitary conditions, 1446.

Opinions that Rats not important Agents in spreading Plague:

Did not convey infection to ships at Bombay, 17,677.
Doubtful whether they spread infection, 5498.
Epidemic at Palanpur cannot be traced to rats, 13,170.
Hubli: No epidemic noticed before outbreak of plague, 1579.
Infection not traced in Hubli district to rats, 1651.
Influence of rats in spreading plague has been exaggerated, 25,831.
No evidence how far they spread the disease, 5853–4.
Not charged with infection in Hubli district, 1651.
Plague spreads along lines of human communication, not by rats, 16045.
Rats become infected simultaneously with man, not before, 18,436–7.
Rats have little influence in disseminating plague, 17,678.

„ Spread.
„ Virulence of bacillus of plague.

REACTION DUE TO INOCULATION.

See Inoculation with Haffkine's plague prophylactic.

RECRUDESCENCE OF PLAGUE.

See Recurrence of plague in infected towns and villages.

RECURRENCE OF PLAGUE IN INFECTED TOWNS AND VILLAGES:

Due to cause not traceable:

Recrudescence cannot be prevented by exertions in any big city, 7868, 7908–11.
Ahmednagar: Possible instances of villages infected in one year from infection that had lain dormant in neighbouring villages infected the year before, 24,099–106.
Alibag: Second epidemic started spontaneously in, probably from last year's germs which remained dormant, 17,620, 25,878.
Bandra: Recrudescence after 24 months, 19,086–94.
Baroda: Second epidemic began in October 1897, in the same part of the town as the first epidemic, 14,596, 15,335.
Bombay: Second epidemic, December 1897, 2.
Cutch Mandvi: Recrudescence began among the Salats, who escaped in the first outbreak, and was not due to imported cases, 13,411.
Dhamdachha: Without apparent cause of infection, fresh outbreak at, 15,119.
Kanaswadi: Supposed recrudescence in, 24,542.
Kotri: Local origin of the second outbreak, 12,710.
Kotri: Recrudescence without any obvious cause at, 3795, 3820.
Kotri: Date of last case in first epidemic, May 9th, 1897; first recognised case in second outbreak, October 28th, 1897, 12,580, 12,581.
Kotri: First diagnosed cases of plague in second outbreak dotted all over the town, 12,595.
Sirohi State: Recrudescence of plague, 9713, 9810.
Surat: First case in recrudescence had lived long in the town, and first four cases occurred together, their origin being untraced, 15,594.
Thana: Bassein: Recrudescence due to a permanent source of infection present, 18,778.

RECURRENCE OF PLAGUE IN INFECTED TOWNS AND VILLAGES—*cont.*

Due to Re-infection:

Most generally re-infection is due to re-importation, 22,717.
Nasik: Out of 200 cases only five in houses where plague appeared during first epidemic, 24,510.
Panjab: Recurrence of plague in villages due to re-infection, 10,051–2.
Poona: Infected a second time from Kirki, 21,579.
Poona, &c.: Second outbreaks in, may have been due to re-infection, 7911.
Thana: Recrudescence generally traceable to second infection, 18,797.

Severity of Plague on its:

Bandra: Recrudescence with increased virulence in, 18,926.
Bandra: Type of plague most virulent in third epidemic, 19,084.
Bombay: Third epidemic in, more virulent than the two first, 18,472, 17,888.
Daman: Second outbreak less severe than first, 58.
Karachi: First outbreak spread very slowly, second very fast, 11,105, 11,221.
Karachi: Second epidemic more virulent than the first, 3692.
Poona: Course of second epidemic, 21,683.
Poona: Third epidemic entirely different in its aspect from the former two, and very much more virulent and more rapid in spreading, 25,860.
Second epidemic more severe than the first in all localities, 7868.
The disease seems to increase in virulence with every repeated outbreak, 25,860.

RECURRENCE OF PLAGUE IN THE SAME HOUSE OR LOCALITY.

Adumbar: Outbreak of plague on people visiting houses to disinfect them, 22,372.
Ankleshwar: Instance of a person contracting plague by sleeping in an evacuated disinfected house, 14,412.
Bandra: Recurrence in the same houses visited by plague during first and second epidemic, 19,090.
Bangalore: More than one case occurred in 297 houses, 25,031.
Bantwa: Increase of plague when people driven back to the town from camp by a storm, 17,558–9.
Bantwa: Sixteen cases occurred in house in, some after disinfection, 17,589–92, 17,595.
Baroda City: Plague decreased on evacuation, but increased when people returned to city on account of rains, 15,234.
Baroda: Savali: Cases again occurred on return of people to their houses on account of rain, 14,658.
Bassein: Recurrence of epidemic in the same spot notwithstanding repeated disinfection, 18,779.
Belgaum: Sweepers' quarter evacuated and reoccupied in ten days, when more cases: residents were then cleared out indefinitely, 2090–7.
Belgaum: Several cases in disinfected houses, 22,835.
Bombay: After disinfection of chawls, plague always recurred in them on reoccupation, 25,790.
Bombay: A good house, 45, Argyle Road, continually attacked in spite of disinfection, 19,437.
Bombay: Cases appear after disinfection, 1211.
Bombay: Cases recurred in 1899 in same houses and same rooms as were infected before, 25,227.
Bombay: Large number of cases suddenly occurred in a particular chawl, 22,382.
Bombay: Many houses reinfected on reoccupation after disinfection, 20,439.
Bombay: Umarkhadi Jail; series of cases in persons sleeping in a particular part of the jail, 20,331–8.
Bulsar: Plague recurred on reoccupation in houses disinfected with perchloride and of which roofs were opened up, 16,236.
Cutch Mandvi: Bada, and Salaya: Plague on revisiting infected houses, 13,431, 13,456.
Cutch Mandvi: Numerous cases in same houses in first epidemic when people not removed; similar series of cases not noticed in second epidemic when houses vacated, 13,440.
Hinganghat: People from camp come to fetch grain from infected huts. Revives plague, 6008, 6024, 6055, 6069.
Hubli: A man who went to his infected house from camp sickened of plague within 11 days and died, 20,076.
Igatpuri: Failure of disinfection, and recurrence of plague in houses, 23,196.
Instances observed at Bulsar and Surat of recurrence of plague in disinfected houses, 24,451.
Karachi: Case of plague through surreptitious occupation of police lines when evacuated, 14,412.
Karachi: Plague on premature occupation of disinfected houses, 11,266, 11,268, 11,271, 11,276.
Karachi: Recurrence of plague cases in disinfected houses if only left vacant for 10 days, 25,198.
Kaira: Common occurrence of plague cases among persons returning to houses which were not infected at the time of evacuation, 14,070.
Kankhal: Attacks due to visits to Jawalapur for disinfection of infected houses, 9226.
Kotri: Death from plague in the only house which had escaped disinfection, 12,648.
Kotri: Case of recrudescence in disinfected house, 12,559.
Mysore City: Particulars of houses in which plague cases recurred, 25,031.
Nasik: Persons attacked at Trimbak on revisiting infected temple, 12,812.
Pademal: Plague on revisiting infected houses, 22,737.
Palanpur: Increase of plague on evicted people re-entering the town to visit temple for Diwali festival, 13,080.
Panjab: Compounder attacked after visit to infected house, 10,588–91.
Panjab: Plague in evacuation camps due to visits to infected houses, 10,758.
Poona: Cases often recurred in houses even after disinfection, 21,614.
Porbandar: Cases again broke out on premature return to the town on advent of rains, 31,678.
Satara: Jailor's house infected three times after thorough disinfection, 22,062, 22,137, 22,330, 22,384–5, 22,535, 22,549.
Satara: Ten cases observed of recurrence of plague in same houses, 22,549.
Sirohi State: Recrudescence of plague in, in houses disinfected by perchloride, 9712.
Sukkur: A large number infected by a plague case in temple, in which five disinfecting coolies also died, 18,403.
Surat: Cases during the second outbreak in the same houses and the same rooms where they occurred in the first, 18,473.
Surat: Plague reappeared in eight out of ten evacuated localities, 15,781, 15,818.
Surat: Recurrence of plague in thoroughly disinfected houses, 16,111.
Surat: Table showing the re-infected localities with period of freedom, II. 299.

See Camps: *Return of people from camps to evacuated houses, and spread of plague in.*
„ Evacuation: *length of period.*
„ Incubation period: *Incubation period in cases contracted by visits to infected places and houses or contact with the sick.*

RECURRENCE OF PLAGUE IN THE SAME PERSONS:

Baroda: A second attack of plague in a woman about a year after the first, 15,123, 15,133–42.
Belgaum: Case of boy who had two attacks, in November 1897 and February 1898; recovered, 23,103–7.
Bombay: Case of a man who died in Modikhama Hospital of his third attack, 19,348–54.
Bombay: Case of Ghella, who was twice attacked, 19,355–9.
Bombay: Case of Mr. Munchershaw, who had plague three times, 19,520–40.
Bombay: Dr. Davur's case, who died of plague in a second attack after recovering from a first attack and being inoculated, 18,017.

RECURRENCE OF PLAGUE IN THE SAME PERSONS—*cont.*

Bombay: Instance of a second attack of plague, 22,492.
Bombay: Instance of a person attacked by plague three times, 19,108.
Bombay: Mr. Champaklal Thakurdas twice attacked by plague, 19,541–96.
Bombay: Mr. Narayan Muljee, three distinct attacks of plague, 19,597–628, 20,525.
Bombay, Parel Hospital: Two cases, 7261.
Bombay, Parel Hospital: A sweeper who had plague in December got the disease again next March and died, 7,219 (3).
Bombay: Two cases recorded; one died, I. 381.
Cutch Mandvi: Case of second plague attack; recovered, 13,492, II. 471.
Daman: Person attacked in 1897; recovered, inoculated, and attacked a second time a month later, 16,554.
Daman: Case of fisherman who had three separate attacks within six months, 16,655, 16,704–40.
Daman: Case of a man who had two attacks, 16,652–4, 16,684–703.
Daman: Instances of persons attacked by plague a second time, 16,649–51, 16,673–83.
Panjab: A case of recurrence of plague in which the second attack was milder than the first, 10,830.
See Relapses.

REGISTRATION OF DEATH:

Opinions and Recommendations regarding:

Certificate of death, impossible in 90 per cent. of cases, 1126–40.
Death certificates would be very unpopular, 8014.
Decline of mortality from other causes during plague mainly due to defect in the report of the village officers, 23,289.
During the rains, reports take a long time to reach the Collector, 22,964.
Half the people are not attended by men qualified to declare cause of death, 7701.
Incorrect: Plague returned as chronic rheumatism, 8051–2.
Law should be passed making death registration compulsory within six hours, and removal penal, 10,990.
Native Assistant Surgeon class might be entrusted with the giving of death certificates, 26,761.
Obligation to report deaths generally imposed by Municipal byelaws but not enforced, 23,308–11.
Organised registration system expensive, but more beneficial than the present mode of dealing with plague, 10,993.
Returns forwarded to Deputy Sanitary Commissioner, 1629.
Returns take some time in getting from villages to Sanitary Commissioner, 7919.
Small towns, in, number of deaths approximately correct, but causes of death extremely incorrect, 8054.
Spread of plague among the uninoculated due, in Hubli, to removal of restrictions on the burial of patients without report of death before burial, I. 409.
System of death registration might be practicable in towns, but scarcely in the villages, 26,788.
System of death registration impossible to combat infective diseases, 26,732.
System of death registration without corpse inspection would be very valuable, 26,748.
Village officers inclined to report cases as plague to save themselves trouble, 3.
Village registers kept by the headman, 1627.
Village watchmen incompetent to ascertain cause of death, 10,283.

Particular remarks regarding, in:

Agra: Registration of births and deaths very inaccurate in, 10,280.
Ahmedabad; Death registration by counting the corpses which are carried through the gates, 13,877.
Ahmednagar: First case of plague discovered by death register in, 24,239.

REGISTRATION OF DEATH—*cont.*

Aminbhavi: Interval before increased death rate comes to official notice, 2201–10.
Ankleshwar: The burning grounds guarded by peons and patawalas, 14,298.
Bangalore: Only effective when paid agents were put on at, 2555.
Bombay and Bengal: Government trying to devise better scheme in, 7833.
Bombay: No system of death certificates, 1126.
Bombay: No system of registration of sickness or death, 10,962.
Bombay: Sole death registration at the cemeteries, 25,737.
Bombay: Notification of the cause of death obtained through the police, 17,899.
Bombay: The police and municipal registers of deaths quite correctly kept for the last 25 years, 17,751.
Bombay: Information obtained from friends at the cemeteries, 1115.
Bombay: If no evidence, plague is assumed as cause of death during epidemic, 1134.
Bombay: A large amount of under registration, but also an amount of over registration of plague, 907.
Bombay: Proposed system of improved death registration, 25,740.
Bombay: Allowing an office for every 5,000 inhabitants, 160 registration offices would be required, 10,991.
Calcutta: No system of death certificates at, 6512.
Calcutta: Hindus and Muhammadans dead against registration, 7549.
Calcutta: Number of deaths obtained at burning and burial grounds. Not cause of death, 6510.
Calcutta: Mortuary returns very unsatisfactory; they give an idea of the general number of deaths but not of the causes, 7522.
Calcutta: Many plague cases returned under false names, 7523–5.
Calcutta: Fever cases wrongly returned to avoid suspicion, I 471.
Central Provinces: Deaths in rural areas reported by policemen, 6139.
Cutch Mandvi: No death registration measures taken during the plague in 1897, statistics imperfect, 13,374.
Daman: Sepoys kept on the burying ground of the Mussulmans and cremation places of the Hindus to report the deaths, 16,417.
Daman: No regular compulsory death registration, 16,641.
Dharwar: Weekly return of deaths sent to each native magistrate of a village, who reports to collector, 1636.
Hardwar: System of registration organised during the presence of plague in the villages, 9205–9.
Hubli: A good many plague deaths escaped record, 1590.
Hubli: Death certificate system introduced during plague worked well, every case being seen and no burial allowed without certificate, 3075–7.
Hubli and Dharwar: System in, supervisors go round weekly, 1665–6.
Hubli and Dharwar: Ordinarily done by municipal authority; taken over by plague staff, 1623.
Hyderabad State: Death returns are kept with the village records by the headmen, police, and revenue patel, 5855.
Karachi: Death certificates from volunteers and municipal commissioners accepted for children under two years of age, 12,790.
Karachi: Death registration enforced by law, obligation to report in two days; period reduced to immediate report after plague outbreak, 11,290–1, 13,222.
Karachi: Death returns made by plague superintendent, 11,287, 11,386.
Karachi: Of death, very accurate at, 11,408.
Madras: Death returns as to number accurate, but not as to cause, 4353–4.
Madras Presidency: Method of, 3894–900.
Mysore: Most accurate, 24,257.
N.W. Provinces: The sweepers report deaths to the municipal office, 8855.

REGISTRATION OF DEATH—*cont.*

N.W. Provinces: No part of India in which the system of death registration is so efficiently carried out, 8858–62.
Panjab: Deaths registered on report by village watchmen to the police, 10,280.
Poona: a byelaw existed regarding reports of death, but was not enforced, 21,553–6.
Rohri: Death certificates required for disposal of dead; police observe burning huts and burial grounds, 12,026.
Satara: Punctual compliance with the order for notification of deaths within 72 hours, 22,566.
Surat: Death registration very deficient, 15,829–50.

REGISTRATION OF INOCULATED PERSONS.

See Inoculation with Haffkine's plague prophylactic.

RE-INOCULATION.

See Inoculation with Haffkine's plague prophylactic.

RELAPSES:

Case recovered on 15th November: recurrence of plague on 2nd December, 1229.
Gadag: woman who left the hospital cured after a mild attack got plague again in eight days, 23,710–7.
Relapse very common, 50 or 60 per cent. develop an iliac or pelvic bubo, 20,923.

See Recurrence of plague in the same persons.

RELAPSING FEVER:

Many cases sent to plague hospitals proved to be of relapsing fever in Bombay, 25,732.

See Diagnosis of plague.

RELIGION AND INFLUENCE OF RELIGIOUS HABITS ON LIABILITY TO PLAGUE:

Ankleshwar: Among Hindus (who are more numerous), majority of plague cases at, 14,953, 14,444, 14,448.
Bangalore: Plague and religion, 25,015.
Baroda: Statistics regarding, 14,989, 15,219.
Bombay: Hindus suffer worst at, because of their low standard of living, I. 352.
Bombay, Parel Hospital: Statistics of plague by religion, I. 257.
Christians in the village of Vadala sleeping in beds more immune than the Hindus sleeping on the floor, 19,446.
Christians show a high mortality at Calcutta, 6554.
Christianised Hindus, Bombay: The lower mortality among, attributable to their diet being better, 17,685.
Cutch Mandvi: More recoveries among Muhammadans than Hindus, 13,479.
Hindus more feeble than Muhammadans, and have less vitality, 27,041.
Hindus resist plague less than the Muhammadans, the resistance of lower caste being less than that of the higher, I. 349.
Influence of religious habits on plague, 17,681–6.
Karachi: Statement of cases by castes and religions, 11,827, 12,356.
Kotri: Hindus only attacked in first epidemics, 12,578.
Kotri: Of the 100 cases of the second epidemic, 77 were Hindus, 25 Muhammadans, 12,639.
Kumaun: Hindus very dirty, 6159.
Muhammadans not more liable to the disease than Hindus, 10,810.
Muhammadans suffered less than Hindus at Mandvi, 13,478.
Muhammadans singularly exempt at Surat, 15,635.
Muhammadans suffered most in Bangalore and Mysore, 25,016.
Muhammadans suffer severely at Bangalore, 2598.
Mussulmans suffer more than the other communities at Daman, 16,424.
Mysore City: Statistics of plague and race, 25,015.
Parsees in Surat, had 11 imported cases but no indigenous case, 15,632.
Parsees live in better parts of the town, and are clean in their habits, and suffer less than other communities, 12,358.

RELIGION AND INFLUENCE OF RELIGIOUS HABITS ON LIABILITY TO PLAGUE—*cont.*

Rohri: About 5 Hindus to every Muhammadan present during plague; 7 cases among Muhammadans and 111 among Hindus, 12,091–3.
Surat: Hindus suffered most, being more overcrowded than the Muhammadans; Parsees and Europeans living in good houses suffered little, 15,632–4, 15,637–8.
Surat: Statement of cases according to religions, 15,635, 15,642.
Well-fed Muhammadans and Memons little liable to infection and less attacked than Hindus at Karachi, 11,898.

See Inoculation with Haffkine's plague prophylactic.

REMOVAL OF MORIBUND PATIENTS TO HOSPITAL:

Condemnation of:

Bangalore: Removal of moribund patients considered an inhuman measure and forbidden, 2628, 2679.
Bombay: Moribund patients not removed 25,635, 25,560–1.
Chances of recovery reduced 50 per cent. if removed to hospital in dying condition, 12,494.
Patients should not be sent to hospitals when moribund, 2628, 7866.
People taken to hospital that would have recovered if let alone, 8126.
Poona: All patients except the moribund removed to hospital, 25,841.

Mortality in Hospitals of Patients within 24 hours of admission:

Ankleshwar Hospital: Of 141 deaths, 61 occurred within 24 hours of admission, 14,443.
Baroda: One hundred and forty-three out of 342 patients died in 24 hours, 15,266.
Bombay: Thirty-eight per cent. of cases died within 24 hours of admission in Arthur Road Hospital, Bombay, 25,734.
Calcutta: Many people taken to hospital in moribund condition, 6551.
Gadag: Of 334 admissions 60 died within 24 hours of admission, 23,692.
Karachi: Death-rate within 48 hours after admission to hospital, 60·4 per cent., 12,419.
Sassoon Hospital, Poona: 34·5 per cent. died within 24 hours of admission, 12,897.

REMOVAL OF THE SICK TO HOSPITALS:

Arrangements regarding:

Ahmedabad: Plague cases at once removed to hospital and contacts to segregation camps, 13,926.
Belgaum: Patients not removed to hospital unless voluntarily, 22,808.
Bombay: Many cases sent to plague hospitals proved to be relapsing fever in, 25,732.
Bombay: Measures directed chiefly to removal of patients to hospital, 17,865.
Bombay: Persons attacked with plague in, removed to hospital, 10,953.
Bombay: Policy to remove patients to hospital, 923–33, 25,559–61.
Calcutta: First epidemic; one of the principal measures, 6,520.
Calcutta: Second epidemic; policy of compulsory removal abandoned, II. 532 (6).
Concealment of cases threatened with removal to Government hospital, 13,157.
Daman: Plague patients removed to hospital, contacts left in the house, 16,369.
Karachi: Removal of the sick not enforced at first, 11,109.
Karachi: Many sick removed from infected to non-infected areas without permission, such removal prevented by making cases so removed liable to removal to hospital, 11,111–2.
Karachi: Sick segregated and removed to hospital later, 11,620–3, 11,952.
Poona: Sick in first epidemic removed, 10,914.
Surat: Disease reduced to 30 per cent. within one month by removal of sick cases to hospital, 16,005.

REMOVAL OF THE SICK TO HOSPITALS—*cont.*

Attitude of the people towards:

Bangalore: A source of dread and horror to the people, 3239.
Calcutta: Very bitter opposition to removal of patients, 6445.
Compulsion should not be used with regard to removal of patients to hospital or of contacts to camps, 25,095.
Daman: Carriage of sick to hospitals in bullock carts caused many deaths, 16,402.
Government hospitals: General dread of, and especial objection to be taken there on stretchers, 22,656.
Objection to remove the sick to Government hospital in Bombay, 17,865, 18,259.
Removal to hospitals disliked, 8260.
Removal to hospital an objectionable measure from Indian's point of view, 16,232.
Resentment owing to the manner people were conveyed to hospital, 17,952.
Satara: Removal of patients to plague hospital very offensive to people, 22,542.
Worrying the people about sending their patients to hospital leads to concealment, 25,806.

See Concealment of plague cases.
,, Isolation of the sick.
,, Removal of moribund patients.
,, Treatment of the sick in their own houses.

RESPIRATION:

Clinical Feature of Plague:

Grave cerebral and respiratory symptoms in cases without marked bubonic enlargement, 12,897.
Hurried and oppressive respiration marked in cases without bubonic swellings, 12,897.
Respiration generally hurried, voice disconnected and slurring, 12,399.
Respiration hurried, I. 380.
Respiration in pneumonic cases much more hurried than in other forms of plague, 12,914.

RETURN OF PEOPLE TO THEIR HOUSES.

RIVERS:

Belgaum: Nearness of a place to a river has no connexion with the prevalence of epidemic, 22,954.
Dharwar: Plague spread along the river, but did not cross it, 23,227–40.
Satara: Epidemic confined to towns and villages along the bank of the river, 22,147.
Satara: Most villages in the affected talukan are on the river, 22,707.
Surat: River precautions, 15,543.

ROAD INSPECTION:

Baluchistan: All suspicious cases detained; no plague found, 8081, 8094.
Bijapur: Road posts to perfect Bagalkot from Kaladgi, 23,635.
Bombay routes guarded, and all but two closed to foot traffic, 1291.
Hubli and Dharwar: Road posts instituted, 1585.
Hyderabad State: Patrolling roads assisted in keeping out the plague, 25,916.
Hyderabad State: Roads watched, 5151.
Poona: Road patrols, 21,299–301, 21,327–8.
Sion Causeway: Seventy-three cases detected, 180 at Mahim Bandra Causeway, 1291.
Statistical results of inspection, 1291.
Surat: Road precautions, 15,541.

ROLL-CALL:

Ankleswhar: Daily roll-call at in order to detect cases, 14,273.
Bangalore: Census at Civil and Military Station during epidemic, I. 107.
Baroda: Residence in camp checked by roll-call, morning and evening, 14,620.
Baroda: Census of villages taken and checked, 14,651.
Bulsar: Census taken and carefully checked, 16,288, 16,296–306.
Hyderabad State: Census of villages in infected area taken and checked, 5465.
Khandesh: Daily roll-call best means of control, 24,588.
Kotri: Population of the town checked every day at, 12,628.
N.W.P.: Beneficial result of appointment of inspecting officers, who checked census of villages for the discovery of newly-infected areas, 9934.
N.W.P.: Roll call in camps, 9169, 9334.
Panjab: Cases in which one person was substituted for another in the roll-calls, 9972–6.
Panjab: Differences between population actually present and roll-call numbers, 9938–44.
Poona Cantonment: Population checked by nominal rolls, 10,907, 21,259.
Poona City: Second epidemic; roll called in segregation camps every morning to ensure presence of segregated people during night, but people allowed to go where they wished during the day, 21,964.
Umreth: Census and daily roll-call, 14,034–6.

SANITARY CONDITIONS:

Existing Conditions:

Ahmedabad: Defective sanitation in, 13,956.
Bangalore: Number of houses in the city and of pit and conservancy privies, 3386.
Bangalore: Sanitation defective, 3250.
Bangalore: Table of statistics of several kinds of houses, I. 128.
Bangalore: Water of wells contaminated by the soakage of the dirt in the yard, and for mixing with the milk, I. 179.
Baroda: Sanitary conditions bad, 15,193.
Bombay: Ashpits non-existent in, galis take their place, 856.
Bombay: Chawls, central passages not kept clean on account of dispute regarding liability between landlords and tenants, the former being legally responsible, 263, 864.
Bombay: Chawls dirty, 16,985, 26,638.
Bombay: Conservancy system, 25,754–66, 25,774–8.
Bombay: Domestic sanitation of the Tarwadi district on the latrine and basket system, 17,861.
Bombay: Drainage arrangements: more than a quarter of the island without drains, 25,741–53.
Bombay: Excessive over-crowding and dirt in the chawls, 16,985.
Bombay: In some parts, basket system of scavenging is practised, 25,754.
Bombay: Mandvi quarter built on the former sweepings of, 19,177.
Bombay: Mortality from phthisis and the lower forms of fever attributable to bad sanitation, 885.
Bombay surroundings very unhealthy, 1,971.
Calcutta as insanitary as Bombay, 7242.
Calcutta bustees in no way sanitary, 7632.
Calcutta: Conservancy rendered difficult by coolie strikes, I. 471.
Calcutta: Description of some of the worst areas of the town, I. 463.

SANITARY CONDITIONS—*cont.*

Calcutta: Fearful sanitary condition of parts, I. 464.
Cutch Mandvi: Extremely bad sanitary conditions, I. 351, 13,349–53.
Dharwar: Sanitary conditions bad, 2305–27.
Karachi: Existing sanitary conditions very bad, 22,649.
Mysore decidedly more insanitary and water-logged than Bangalore, 24,984, 25,043, 25,124–7.
Rohri: A particularly dirty town, always ravaged by small-pox, and has a high rate of mortality, 12,049.
Villages: Sanitary conditions in, 7922.

Improvements in Sanitary Conditions:

Ahmedabad: Sanitary improvements effected in the cantonment whilst people were out in camp in, 24,191.
Ahmedabad: Sanitary improvements have reduced the ordinary mortality of the town as compared with the previous five years in, 24,347.
Bangalore: Improvement begun by building new quarters, 3481.
Baroda State: Sanitary improvements effected in, 15,154–66.
Bombay: Drainage has improved the health of the people, 25,767–73.
Bombay: Dustbins to be provided, 874.
Bombay: Great improvements made in recent years in parts of the town, with regard to light and ventilation, 25,702.
Bombay: Improvements in sanitation generally handicapped by want of funds, 19,761.
Bombay: Landlords prefer paying fines to making the required improvements in sanitation, 17,861.
Bombay: Notices to landlords for sanitary improvements, only one-fifth have been acted upon, 18,275.
Bombay: Lord Sandhurst's "Improvement Scheme" will be a failure unless people can be taught to believe in fresh air, 22,377.
Bombay: Proposed laws for the improvement of the sanitary condition, 25,278.
Bombay: Shone system of drainage introduced in certain districts, 25,752.
Bombay: Statement showing the numbers of houses marked U. H. H. in each ward, in 1897 and 1898, III. 310.
Calcutta: Improved of late years, even the back galis are comparatively clean now, 7148.
Calcutta: Native quarter very much the same as 60 years ago, I, 464.
Calcutta: Sanitation greatly improved; hence slow spread of plague, 7148–50.
Calcutta: Sanitation improving, 6656.
Cutch Mandvi: Great improvements since epidemic in sanitary arrangements, 13,506.
Great progress made in last 10 years in India, list of larger works done, 7838–40.
Impossible to introduce an effective system of sanitation where money is scarce, 2561.
Karachi: Sanitary improvements effected since plague, 22,654.
Machis object to light being let into their houses, 15,164.
Not practicable to effectively carry out the sanitary regulations unless the village officers can be depended on, 19,642.
N.W.P.: Sanitary improvements effected, 8843.
Powers of municipal bodies in sanitary matters, 7809–10.
Proportion of municipal income spent on sanitary work, I. 278.
Rural areas: The sanitary reforms attempted and required in, 7841, 7922.
Sanitary improvement complicated by political considerations, 7925.
Scheme for promoting the knowledge of personal and general hygiene among the people of India, III. 292.
Surat: Golas refused to move from their insanitary dwellings; municipality too poor to compel them, 24,459.
Surat: Improved sanitation since plague, pit privies closed, 15,927–36, 24,459.

SANITARY CONDITIONS—*cont.*

The Bombay Municipal Bill ought to be extended to the whole of India, 26,712.
Want of money rather than want of advice the great obstacle to sanitary improvements in India, 17,238.

Influence of Sanitary Conditions on Plague:

Ahmednagar: Plague broke out in an unhealthy part of the town which is open, where there was no drainage system, 24,228, 24,264.
Bad ventilation, over-crowding, and dirt the principal factors in the propagation of the disease, 14,388.
Bad water, damp, filth, and bad conservancy favour plague, 15,151.
Bombay: In new streets attacked houses overcrowded and with defective ventilation, 25,784–5.
Bombay: Outbreak in the insanitary Mahalakshmi temples, 1545
Bombay: Plague just as bad in the new streets where lighting and ventilation are improved as in the old parts of the city, 25,700–15.
Bombay: Severity of epidemics generally can be estimated beforehand, according to the buildings and the classes of the population, 890.
Bombay: Sewer pollution not the cause of plague, 19,437.
Cutch Mandvi: The disease propagated by insanitary conditions, I. 351.
Defective lighting and ventilation and keeping cattle in houses favour plague, 23,180–6.
Evidence on the sanitation of Bombay, the origin and course of epidemic, and the measures adopted to stop it, I. 39–52.
Excess of moisture of soil, general vitiation of the air by over-crowding and temperature, the predisposing conditions to plague, 17,354.
General insanitary conditions, over-crowding, &c. develop plague, 2923.
Hygienic conditions probably cause improvement in general health and check plague, 21,718–9.
Incidence of plague greatly influenced by the conditions under which the people live and their surroundings, 14,446.
Insanitary surroundings, bad ventilation, and moist floor in plague houses, 21,548.
Karachi: Civil station remained non-infected during the second epidemic, 11,345.
Karachi: Disease spreads very rapidly in the market quarter because plague broke out there and was assisted by unsanitary conditions, and also spread by rats in the granaries of the quarter, 22,654–6.
Karachi: Drainage system not responsible for the severity of the outbreak, 22,651.
Karachi, Poona, and Bombay: Improved cleanliness of the towns did not check the disease in the second outbreaks, 3704, 8707.
Kumaun: Prevalence of plague due to insanitary conditions and keeping grain and cattle in houses, II. 361.
Outdoor life the reason of immunity of certain classes, 22,129.
Over-crowding, lowering of the vitality, habitual disregard of hygienic rules cause plague, 25,263.
Plague cannot appear and spread in sanitary surroundings, 26,709–10.
Plague does not assume a virulent form where sanitary arrangements are good, 11,851.
Plague found only where dirt, dampness, and over-crowding prevail, 21,323.
Plague spreads by insanitary conditions, 1442, 7180.
Plague worst in insanitary houses, and can be more easily stamped out in sanitary houses, 24,363.
Relation between bad sanitary conditions and plague not so clear as in other diseases, 8707.
Rohri: Failure of evacuation at, owing to insanitary condition of camps, 12,129.
Rohri: Heavy mortality among the people from the suburbs attributed to the neglect of all sanitary measures, 12,082.

SANITARY CONDITIONS—*cont.*

Sanitary habits the secret of social immunity, 22,412.
Surat: Plague worst in the worst localities, 15,938.
Under hygienic conditions attacks very rare, 15,193.
Insanitary conditions the principal factor in the spread of plague, 15,149.
Want of ventilation, dirt, and over-crowding responsible for virulence of plague, 3386, 11,228, 11,281.

Sanitary Improvement as a Plague Measure:

Extinction of plague and the prevention of recurrence depends upon sanitation, 26,712.
Sanitation the essential thing to stop plague, but expensive, 7999–8000.
Sanitary improvements should not be started during the epidemic, 15,223.
Sanitary improvements the only real way of attacking plague, 7837.
Sanitation is essential in order to exterminate plague and the prevention of recurrence, 26,712.
Sanitation should be first line of defence against plague, I. 408.
Sanitation and raising the moral tone of the people by gentle measures best means to fight the disease, 24,935.

SANITARY DEPARTMENT:

Board:

Administrative power of Sanitary Department, 17,169.
Boards do a fair amount of work in a quiet way, 8034.
Boards do work without holding formal sittings, 7958.
Civil medical administration in the Bombay Presidency, system of, 17,147–56.
Constitution of Sanitary Board, 7799, 7806.
Constitution of Sanitary Board in the Panjab, 10,500–6.
Legal enforcement of sanitary measures in the N.W. Provinces, 8845–9.
No scheme involving an expenditure over Rs. 1,000 is passed in the N.W. Provinces until the Sanitary Board has approved of it, 8853.
Note on the N.W. Provinces Board and on the works it has executed, Vol. II. App. XXVII.
Reports on sanitary matters in Bombay sent to Surgeon-General's office, who forwards them with recommendations to the District Collector, which are seldom acted upon for want of funds, 17,207.
Sanitary Board in Bombay, constitution of, 17,162–8.

Commissioner, Sanitary:

Commissioner can take no direct action by himself, 7753.
Commissioner has advisory duties, no executive functions, 7725.
Commissioner now put under Inspector-General to give him control of hospitals, 7757–8.
Commissioner responsible for vital statistics and vaccination, 77–9.
Duties of Sanitary Commissioner and his staff, 19,702–11.
Method of selecting Sanitary Commissioner, 7938–42.

Inspectors:

Advantage if Inspector could diagnose plague, 3982.
Hospital Assistants are not so well educated as Sanitary Inspectors, 3974.
Inspectors on their round gather information as to plague in villages, 14,435.
Inspectors paid 70 rupees a month in Madras, 3956.

SANITARY DEPARTMENT—*cont.*

Inspectors must have matriculated at Madras University, 3922.
Inspectors would be the better for a medical education, 3983.
Inspectors not medical men in Madras Presidency, 3920.
Surat: Sanitary Inspectors have no medical training, 15,833.

Organisation:

A new organisation of the Sanitary Department of India most urgently required, 26,791.
At present staff is insufficient and ineffective, 26,793.
Each district should have a Sanitary Officer; estimated cost, 1 anna per head of population, 8002–6.
Question of control of District Medical Officers by Head of Sanitary Department as well as by Head of Civil Medical Department, 7960–6.
Scheme by which Assistant Superintendents of Vaccination would be Assistant Surgeons with a knowledge of sanitation, 8881.

See Civil Medical Department.
,, Civil Surgeons.
,, Health Officers.

Special Arrangements for Emergencies:

Hardwar: Sanitary staff increased on the occasion of large fairs, 2012.
Hardwar: Special precautions taken during the fairs in April, 9023–4.
Staff of Health Department, Bombay, greatly increased during last epidemic, 25,727.

SANJAR:

See Mahamari and Sanjar.

SCAVENGERS:

Strike of the conservancy establishment at Calcutta, I. 471.
Strike of the sweepers at Bangalore, 25,091.

Plague among:

Bangalore: Several cases among the scavengers in, 3226.
Bombay: Scavengers in first epidemic in, notably free, I. 378.
Scavenger dies of plague at Molagavelli, 4435.
Sweepers, as well as other dirty castes, not much attacked, 22,266.
Sweepers escape because bacillus dies in the dirt with which they deal, 1004.
Sweepers first infected in Belgaum, 2086.
Sweepers, on account of their filthy work, have, to a certain extent, become immune, 18,642.

SEARCH PARTIES.

See House Searches.

SEASONAL VARIATION OF PLAGUE:

Chart showing seasonal variation in Bombay City, 26,549, Vol. III., Apps. LXXVII., LXXVIII., LXXXV.
Fresh colonies of rats continually get plague in the Mandvi quarter and spread it, 17,837.
Suggestion that plague rises in Bombay when the season for export of grain ends, as rats then resume activity in spreading the disease, 8277.

SECOND ATTACKS.

See Recurrence of plague in the same person.
,, Relapses.

SEGREGATION:

Advisibility of: opinions regarding:

Compulsion should not be used with regard to removal of contacts to camps, 25,095.
Evacuation an excellent measure if combined with segregation, 11,482, 12,051.
Evacuation, segregation, and disinfection valuable in the order named, 23,032.

SEGREGATION—*cont.*

In villages segregation unnecessary beyond the removal of the sick and their attendants, 18,781.
Isolating the contacts most necessary, 12,053–5.
Practically impossible, drives inhabitants away, 7043.
Securing of all the contacts one of the principal advantages of voluntary camps, 11,821.
Segregation and thorough disinfection of every house in the place necessary measures in cases of plague, 9436.
Segregation and isolation absolutely perfect in theory, but impossible in India, 7043.
Segregation essential, 13,191.
Segregation should be accompanied by disinfection, 18,426–8.
Segregation, sound in theory, but impossible in large cities, 7996.
Segregation impossible with existing resources in rural areas when many villages infected, 22,743.
Segregation of contacts not recommended, 18,949.
Segregation, relaxation of, of neighbours, resulted in improvement in voluntary reports of cases, 16,029–32.
Segregation with early information, evacuation, and inoculation important, 26,708.
Segregation useless if people are allowed to return to their houses after 10 days, 11,475.

Arrangements for:

Ahmedabad: Contacts at once removed to segregation camps, 13,226.
All contacts placed in segregation camps in Palanpur State, 13,086.
Bangalore: Policy of segregation adopted, 2576, 3261.
Baroda: Segregation adopted, 14,604, 14,618–9.
Baroda villages: Contacts successfully segregated, 15,106–8.
Bombay: Accommodation for 5,000, could be increased to 20,000, 453.
Bombay villages: Complete segregation not attempted, 8–9, 26,662–4.
Bombay: Not allowed to take all the contacts to camps in, 10,953.
Bombay: Removal to camp reserved for people from over-crowded and very poor houses, 8258.
Bombay: Rules of segregation camp, 496.
Cutch Mandvi: People segregated as far as possible, 13,377, 13,440–1.
Daman: Plague patient removed to hospital, contacts left in the house, 16,369.
Hardwar: Arrangements in, 9327–43.
Hubli: Contacts and inmates of infected houses segregated, 1944–5.
Hyderabad (Sind): Contacts segregated in villages, 18,396.
Karachi: At the beginning of outbreak, infected houses evacuated for ten days and all their inhabitants segregated, 12,027.
Karachi: Contacts removed to segregation camps in May 1898, 11,157–9, 11,674, 11,245.
Karachi: People from infected houses, and later from neighbouring houses as well, removed to camp, 11,142, 11,149.
Karad: Segregation and disinfection the only measures adopted, 21,077.
Khandraoni: System of segregation in, 9642–9.
Khandraoni: Villagers divided into four classes and sent to separate segregation camps, 9647
N.W.P.: Segregation strictly enforced, 9331–7.
Panjab: Segregation of patients and friends one of measures adopted, 10,057, 10,450.
Poona: Contacts sent to segregation camp, disinfected and detained 10 days, 19,936.
Porbandar: 3,500 Kharwas put in segregation camp in a few hours; fed by the State at a cost of Rs. 250 a day, 13,671–4.
Porbandar: Residents from the worst infected quarters of, segregated in country crafts mored in the creek, 13,681.
Rohri: People allowed to return to their disinfected houses after 10 days' segregation, 12,034.
Rohri: Segregation camp at, under extremely favourable conditions, 12,064.

SEGREGATION—*cont.*

Rohri: Whole blocks segregated at, 12,032.
Sind: Segregation policy adopted, 12,027.
Surat: All persons in houses where unreported deaths occurred segregated, 15,715.
Surat: Food and blankets provided in the segregation camp from a charitable fund, 24,418.
Surat: Segregation of contacts impossible, as there was no proper accommodation, 24,417.

Attitude towards:

Bangalore: Highly unpopular at, 2622, 3282, 3480.
Bangalore: Objection of Muhammadans to segregate contacts in, 3238.
Calcutta: Panic caused principally by the fear of segregration in, I. 468.
Calcutta: People all refused to go into segregation huts, 7289.
Calcutta: Objection to segregation but not to disinfection, 6545.
Concealment of cases, segregation leads to, 2672, 3390.
Dharwar: 18,000 persons left in one week for fear of segregation, 23,746.
If carried out vigorously would cause great opposition, 1276.
Karachi: People object strongly to Government segregation camps, 12,527.
Nasik: People refused to go to prepared segregation camps, 24,477.
Nasik: About 5,000 people left from dread of segregation, 13,832.
Passive opposition in every large town of India against, got over by tact and firmness, 26,667–8.
People hate being sent to contact camps, 25,818.
Segregation of contacts an objectionable measure from the Indian's point of view, 16,232.
Sholapur: People fly on occurrence of a death to escape segregation, 20,237.
Surat: People object most to inoculation and segregation, 15,865.
Thana district: No opposition to evacuation, segregation very unpopular, 18,788.

See Exodus of people.

Efficiency of: opinions in favour of:

Calcutta: Probably effective in keeping down plague at, 7138.
Chart showing the mortality among Muhammadans at Porbandar for 15 days before and after segregation, II. 222.
Cutch Mandvi: Borah community promptly segregated and treated with Yersin's serum; low rate of mortality, I. 353.
Favourable effect on those removed, 1248.
Khari and Pali: Course of disease the same in, notwithstanding in the latter place the contacts were not segregated, 18,943.
Lessens the number of cases in the same family, segregation of contacts considerably, 13,440.
Results of segregation unsatisfactory for the want of adequate resources, 22,743.
Siddhataki: Stops extension of plague at, 7414.
Vadala: Plague stopped among the Luvana community by placing them in a segregation camp at the first appearance, 13,737.

Failure of: opinions regarding, and instances of:

Bangalore: A failure at, on account of the difficulty of securing the contacts, 2684.
Bombay: Contacts if disappeared generally traced and brought back, 10,917.
Bombay: Found impossible in, 311.
Bombay: Inadequately carried out at, 1200, 4029.
Difficult in Bombay, where 100,000 persons come to earn a daily wage, 1088.
Impossible to get hold of contacts in a crowded chawl, 8261.
Results of segregation unsatisfactory for the want of adequate resources, 22,743.
Segregation and isolation of the sick did not arrest the progress of the disease at Baroda, 14,601.

SEGREGATION—*cont.*

Period of Segregation of Contacts :

Bombay : Contacts taken to camp for 10 days, 1345.
Bombay : People from contact camp allowed to return to their houses 10 days after the last cases had occurred among their family, 10,929.
Dharwar : Contacts detained 18 days, 1920.
Hubli : Segregated people at, allowed to leave after 10–15 days, but not back into the town unless inoculated, 2433–4.
Hubli people kept up to 18 days, 1656, 1902, 1956.

Relaxation of :

Bangalore : With evil effects, relaxed at, 2670.
Belgaum : Owing to rains, people not segregated, 22,806–9.
Bombay : Contacts merely obliged to be in camp at night, 1354, 25,629.
Bombay : In March 1898, segregation modified in, 8258.
Calcutta : Abandonment at, produces no bad results, 7660.
Calcutta : Contacts had to leave infected rooms, but were not segregated or watched, 6591–5.
Calcutta : Practically abandoned in, for reasons of policy, 7610.
Calcutta : Second epidemic ; contacts not segregated, but induced to leave infected houses, II. 532 (6).
Calcutta : Segregation compulsory, early abandoned in, 6535.
Dharwar District : Contacts not segregated in certain villages, 1660–3, 23,541–2.
Igatpuri : Impossible owing to rains, 19,455.
Kalyan : From not segregating the contacts serious results at, 19,661.
Kalyan : Persons paying Rs. 20 or more income tax allowed to be segregated in their own houses at, 19,663.
Karachi : Methods of segregation modified in the course of the epidemic, 11,143, 11,258–65, 11,675, 11,822, 11,894.
Mysore State villages : No segregation of sick or contacts, 3333.
Mysore : The non-interference with the people in town the main cause of keeping plague from spreading to the villages round, 24,970.
Poona City : System modified in second epidemic, 21,694.
Poona City : Third epidemic ; contacts required only to sleep in camp for three nights, 21,817–20.

See Camps.
,, Contacts :
,, Inoculation with Haffkine's prophylactic : *Inducements to inoculation.*
,, Notification of disease.

SEPTICÆMIC PLAGUE :

Clinical characteristics of :

Description of typical course of septicæmic plague, I. 381.
Notes on case of acute septicæmia, I. 439–40.
Septicæmic cases with neither buboes nor pneumonia, 6948.
Septicæmic plague may easily escape detection if attention is only directed to the evidence of buboes, 13,915.
Slight glandular enlargement in plague indicates fatal septicæmia, 6986.

Fatality of :

No septicæmic cases recover, 6950, 12,920, 12,394.
Cutch Mandvi : Usually fatal in six to eight hours, 13,487.

Infectiousness of Septicæmic Plague :

Septicæmic plague not particularly dangerous in spreading infection, as patients die so rapidly, 4371.
Septicæmic plague not specially infectious as cases generally die quickly, 12,481.
Septicæmic plague gave rise to bubonic plague in one case, 16,048.
Septicæmic plague gave rise to septicæmic plague in one case, 16,048.

SEPTICÆMIC PLAGUE—*cont.*

Septicæmic Plague contracted from Bubonic Cases :

Bubonic plague case gave rise to a case of septicæmic plague with secondary pneumonia, 13,003–13.
Difference between septicæmic and bubonic the lesser resistance of the glands, I. 368.
Septicæmic plague contracted from bubonic ; 10 instances, 16,048.
Septicæmic shades into bubonic form, I. 471.

See Post-mortem appearances of plague.

SEQUELÆ OF PLAGUE :

Complete deafness followed plague in one case in Daman, 16,823.
Complete disintegration of the orbits and disease of the eyes followed plague, 16,770, 16,822, 16,833, 20,896–901.
Gangrene a sequela of plague, 16,750, 16,778, 20,885.
Hemiphlegia followed plague, 16,766, 16,832.
Inco-ordination a sequela of plague, I. 383–4.
Lunacy after plague, 17,582, 20,791.
Neuritis, peripheral, sequela of plague, 20,918.
Paralysis followed plague, 16,763, 16,772, 16,824–31, 16,833, 20,917.
Paraphlegia followed plague, 16,832–33, 20,918.
Speech, loss of, followed plague, 16,820–1, 16,833.
Wrist drop a sequela of plague, 20,918.

SERUM :

Bactericidal effect not noticed in the serum of convalescents from plague, 26,406.
Bactericidal power of the serum of an animal recovered from plague has very little protective power on another, 27,371.
Experiment, reported by Dr. Klein, on animal in which therapeutic serum appeared to hasten instead of retarding the course of plague, 27,350.
Necessity for strict comparability between serum cases and controls in observations undertaken to test the serum, 20,952.
Opinion that in testing serum the earlier the treatment is commenced the better the prognosis, III. 462 (6), 27,045.
Serum treatment in first three days of disease gives worst results, but the better results of treatment after the first three days cannot with certainty be attributed to the serum, II. 459.
Table of experiments made to determine the protective power of various anti-plague sera, and of various combinations of anti-plague sera, III. 336.

See Haffkine's curative serum.
,, Lustig's curative serum.
,, Yersin's curative serum.
,, Widal's test.

SEX IN RELATION TO LIABILITY TO PLAGUE :

Buboes in Women :

Buboes, females mostly axillary, 18,051.
Women in contact ward, Bombay, suffered more from axillary buboes than men, 18,049.

Greater liability of Women :

Baroda, cases preponderant among females 15,361.
Bombay : Female cases more numerous, 18,240.
Cutch Mandvi : Women chiefly attacked possibly because more men than women ran away, 13,477, I. 352
Daman : Women suffered most, 16,521.
Fact that women are, as a rule, more affected by plague than men would point to the floor as seat of infection, 16,216.
Greater proportion of females than males, 18,240.
Panjab : Many villages in which women were attacked first, 10,134.
Women more affected than men, 537.

Less liability of Women :

Calcutta, 1898 : 174 male cases came to notice for every 100 female cases, 6575.
Preponderance of plague cases in men due to their occupations exposing them more to infection, 12,349.
Women less affected than men, 237.

SEX IN RELATION TO LIABILITY TO PLAGUE—*cont.*

Statistics of Plague and Sex.

Bangalore Hospitals: Plague cases by sex, 2913, 2923.
Baroda State: Table of Plague cases according to sex, II. 282.
Bombay: Arthur Road Hospital; plague and sex, III. 459.
Bombay: Incidence of plague by sex and age, I. 392.
Bombay, Parel Hospital: Statistics of plague by sex, I. 257.
Calcutta: Incidence of plague by sex in, 6574–5, 6815, 8049, I. 474.
Calcutta: Concealment of female cases makes statistics doubtful, 6576.
Cutch Mandvi: Plague according to sex, I. 352.
Karachi Hospital: Table showing comparative plague death-rate in different varieties of, among men, women, and children, II. 176*a*.
Karachi: Plague cases tabulated by sex, II. 424.
Kotri: Table of cases according to age and sex, II. 185.
Palanpur: Plague cases by sex, 13,159.
Poona: Statistics of plague cases bearing on sex in Sassoon Hospital, 12,897.
Porbandar: Plague cases classified according to sex, II. 484.
Satara: Figures relating to plague and sex, 22,276.
Surat: Table of gross mortality for the last three years among men and women, II. 301.
Surat: Plague according to sex, 15,645.
Umreth: Table of total attacks and deaths by castes, sex, and age, II. 233.

SHEEP:

Immunity:

Not affected by plague, I. 378.
Secure local immunity after repeated doses of plague virus, 115.

Serum:

Serum of sheep used for curative inoculation, 130–3.

SHIPS:

Disinfection of:

Disinfection of ships carried out under inspection of harbour authorities, 815.
Ship itself thoroughly disinfected before being allowed to leave Bombay, 738.
Treatment of actually infected ships, 12,243–50.

Plague Cases on:

Annie Maude, three cases of glandular fever among the crew of the, 26,934.
Bahaduri, arrived at Karachi with plague cases, 12,171, 12,182, 12,247.
Ballarat, plague on S.S., 765.
Bengal, plague cases on S.S., 762, 765.
Bhundara, report of cases on board S.S., 12,250, 25,495–6.
Booldana, a contact developes plague on board the, 25,491.
Bormida, case of plague on board, 25,506.
Caledonia, two possible cases of plague at Suez, November 1898, 23,489.
Carthage, on S.S., 757–8, 800–8.
Cleobaria had a supposed case of plague 13 days after leaving Calcutta, where there was no plague, 20,648.
Clyde, on S.S., 761.
Dilwara, on troopship, 755–6.
Dwarka landed plague cases at Karachi, 12,165.
Goanese stewards on board P. and O. ship attacked in London, 799.
Golconda, blood samples from a supposed case landed at Plymouth from the, gave negative results, 27,415.
Patna, case landed from, at Karachi, 12,178.
Patna, four cases on the, while on the voyage out from Karachi, 12,243.
Patna, Russian Plague Commissioners certify plague cases on S.S., 763.

SHIPS—*cont.*

Pekin, on S.S., 752–4.
Shannon, on S.S., 759.
Satranji landed plague cases at Karachi, 12,176.

Rat mortality on Ships:

Found dead in S.S. *Shannon*, when plague case was on board, 759, 820.
No rat mortality noticed on ships in Bombay Harbour, 17,677.
Two dead rats found on board the S.S. *Patna*, when plague case occurred, 763, 12,248.

Risk of Spread of Plague by Ships' Passengers:

Medical examination on board ships acts as a deterrent to the travelling of infected persons, 25,482.
Risk of passengers bringing plague by sea much less than by rail, 12,199.

See Port regulations.

SHOPKEEPERS.

See Banniahs and Traders.

SKIN.

Clinical Features of Plague:

Cellulo-cutaneous necrosis, 20,875.
Cutaneous manifestations of plague, 20,868–73.
No local affections of the skin observed in cases of plague, 9571.
Phlegmonous conditions of the skin in cases when no bubo appears, I. 351.
Skin dry and harsh in plague, I. 380.

Discovery of Bacillus in:

Found in four cases in small lesions of the skin, 1393.

See Infection, modes of.

SOIL:

Assertion that Bacillus easily found by Microscopic Observation only in Soil by Hyderabad State Plague Officers:

Assertion that infection tracked from house to house by microscope alone in Hyderabad State, 5730.
Bacillus can be detected at once in soil by microscope, I. 442, I. 447, 5191–4.
Bacillus discovered in floor at Sirsi and in Bombay, 5156, 5159, I. 442.
Bacillus found in soil frequently, I. 442, 5164–99, 5579.
Bacillus invariably found in scrapings of infected houses, I. 442.
Bacillus not found in roof or walls at Hyderabad, 5781.
Bacillus not found in walls or roof more than an inch deep, I. 442.
Bacillus not found in wall scrapings, 5199.
Certain appearance always indicative of plague, 5874.
Evidence as to the cultivation of the bacillus of plague from two samples of earth in Hyderabad, I. 202.
Experiments at Hyderabad to show the existence of the plague bacillus in soil, I. 189–94, 202–11, I. 443–54
Lawrie's experiment for identifying the microbe from mud tested and found fallacious, 8539.
Method of collecting soil from house, 5896–902.
Method of testing adopted by Mr. Stevens, I. 454–6.
Photo-micrographs of suspected floor preparations, I. 443–4, 447, 448.
Rabbits inoculated with suspected soil died faster than rabbits inoculated with virus from plague patients, 5590, 5757.
Results of laboratory investigations to establish discovery of plague bacillus in soil at Hyderabad, I. 358–60.
Scrapings more infected than loose dust, I. 455.
Stalactite formations said to establish identity of plague in cultures made in Hyderabad from soil, 5227.

Soil—*cont.*

Undisturbed corners of the room best place for bacilli; bacillus chiefly found there, 5906, I. 455.

See Rabbits.

Discovery of Bacillus in Soil:

Found in floor scrapings, but probably from sputum, 4574.
Found in floor scrapings taken about one-eighth of an inch from surface, not exposed to sun or air, 676, 680.
Method of collecting soils for examination, 647–85.
Not detected in any part of a plague-infected room, 171.
Not found in blood of rats inoculated with earth from plague-infected rooms, 26,157.
Not found in earth or dust from infected localities, 619–20, 635, 995, 25,347, 26,139, 27,137.
Not found in earth from plague-infected floors or dust from an infected pucka floor, 26,139.
Not found in floor soil, 1456.
Not found in 21 experiments for the discovery of the bacillus in infected floor sweepings and soil from Bombay, Dharwar, and Hyderabad, I. 358–60.
Not isolated from floor scrapings of infected rooms by inoculation in rats, 619.
Soil from infected houses: bacillus morphologically like plague found by CO_2 method, 26,141.
Sterilised earth, details and results of experiments to ascertain whether it can be recovered from, in cultivation with CO_2, 26,434.
Unsterilised garden mould, recovered by CO_2 method from specimens of, 26,144.
Yersin's assertion disproved, that the microbe can easily be detected in the mud of infected places, 8512.

Infectivity of Soil:

Bacillus of plague supposed to be always present in soil, and becomes virulent after the rains, 22,356.
In Kumaun people believe the infection of mahamari to lie in the soil, 8832.
Mortality among rats points to the presence of the plague bacillus in the soil, 19,189.
Plague poison is in the soil, 16,149, 17,364.
Soil becomes infected, 6897.
Soil retains and transmits infection, 7243.
Soil spreads the infection, 21,499.
Theory that infection is spread through unwholesome fermentation in the soil after heavy rains and great heat, II. 42.

Micro-organisms in the Soil:

A larger number of micro-organisms developed from samples of soil taken from inhabited than from uninhabited houses, 18,805.
Average number of micro-organisms in 1 gram of floor material 4,057,800 before disinfection and 228,300 after disinfection, 18,862.
Average number of micro-organisms in 1 gram floor material of occupied houses 3,000,000; of unoccupied houses 1,000,000, 18,805.
Comparison between the number of bacteria found in a house before and after its disinfection, no test as to value of disinfection, 26,369.
List of micro-organisms found in various samples of soil and dust from native dwellings, 18,818.
Seven distinct species isolated from samples of earth from Calcutta, 26,329.

See Carbonic acid.
,, Floors.
,, Hydrogen.
,, Infection by locality.
,, Isolation of plague bacillus.
,, Period for which plague bacillus can survive.

SPEECH:

Clinical Features of Plague:

Aphonia very common, 12,402, 12,901, 16,527, 17,581.

Speech—*cont.*

Eight cases of absolute aphonia; recovery 12,400.
No aphonia noted among patients at Sassoon Hospital, Poona, 12,905.
Thick speech, I. 379, 15,295, 20,675.
Voice disconnected, and slurring, 12,399.

Prognosis:

Improvement in speech good prognosis, 15,310.

Sequela to Plague:

Loss of speech followed plague, 16,820–1, 16,833.

SPIES:

Bombay: Spies and watch on the cemeteries the only means of controlling the chawls in Bombay, 16,987.
Kotri: System of detectives for discovering plague cases, 12,026.
Rohri: Detectives employed successfully to obtain early information of plague at, 12,026.
Use of spies and watch on the cemeteries the only means of controlling the chawls in Bombay, 16,987.

See Informers.

SPLEEN:

Clinical Feature of Plague:

No abnormal symptoms in spleen, 12,411.
Spleen in bubonic plague very much enlarged and congested, 10,421.

Discovery of Bacillus in:

Found in spleen of plague corpses, 7189.
Found post-mortem in spleen, I. 370.

Post-mortem Appearances:

Of spleen in septicæmic case, I. 439.
Of spleen, I. 367.

See Rats.

SPREAD OF PLAGUE:

Animals and Men:

Animals do not transfer plague to one another, 27,343.
Do not seem to spread plague, except perhaps rats, I. 378.
In Kariha plague spread only in a particular class, though rats were affected, 10,123–6.
In Thana spread of plague among particular classes not noticed, 18,789.
No reason for supposing that the virus of plague may be conveyed from place to place, independent of the agency of men or rats, 9480, 9579.
Plague in Surat and Daman spread along lines of human communication, not by rats, 16,045.
Plague spread by human agency or by rats, 19,942.
Spread by human agency chiefly, also by clothes, rats, squirrels, and monkeys, 22,278.
Spread in most cases from person to person or by rats, 20,412.

Instances and Opinions that Human Agency important Agency in spreading Plague:

Ahmedabad: Infection conveyed by Bombay refugees who stayed 3 days, 15,202.
Ahmednagar: Cantonment in, plague introduced by persons sheltering in the city from the, 24,227–8.
Ahmednagar: Conveyance always by human agency, 24,089. 24,303.
Ahmednagar: Plague brought to, by a Mali from Poona, 24,133.
Ankleshwar: Plague introduced from Chandod by human agency, 14,208.
Bandra: Infected by a person who came from Bombay with plague, 18,922, 19,427.
Baroda: Dhers and Mahars, spread plague as they collect and sell rags, 15,337.
Baroda: Spread from place to place by human agency, 15,200.
Baroda: Spread of epidemic to different parts of the town traced to people visiting each

SPREAD OF PLAGUE—*cont.*

other, or to the removal of actual plague cases, 14 608.
Baroda: To the State villages by human agency, plague imported from, 14,644.
Belgaum: Plague introduced by a family which came from Sirur, where there was plague, 23,028–9.
Broach: Plague brought by butchers from Ankleshwar, 15,484.
Bulsar: By human agency, plague brought from Bombay, 19,941.
Bulsar: Plague introduced by Dhebras, who visited Billimora, got plague there, and fell sick on their return, 16,160.
By human intercourse, 10,391–3, 13,456,16,006, 18,756.
Calcutta: Instance to show how contagion is disseminated by human agency, and forms fresh foci of disease, I. 477–8.
Chipagiri: Infected by persons who visited Guntakal and brought plague back with them, 4397.
Cutch Mandvi: Presumed to have been infected by persons from Karachi, 13,366.
Cutch Mandvi: Spread of the epidemic to the villages of Cutch State, 13,398–405.
Dharwar: By human agency from village to village, 1641, 23,502, 23,626.
Dharwar district: Ugargol infected by man who visited Dharwar and brought infection from there, 22,878–85.
Disease introduced by persons coming from infected places, 14,072.
Distinct history of infection by human intercourse in rural and urban areas of Bombay Presidency, 23,207.
Gadag: Many people come from Dharwar and died in Gadag of plague, 23,554.
Ghoti: Plague carried from Igatpuri to Ghoti by fugitives, 16,896.
Hubli: Infection carried by policemen from railway chawls to, 2407.
Hubli: Spread of plague among the uninoculated attributable to the removal of restrictions on the burial of patients without report of death before burial, I. 409.
Human agency alone spreads plague; rats, monkeys, and squirrels hastily condemned, 23,593.
Human agency chief factor in spreading plague, 19,003.
Hyderabad State: Infection carried into the Nizam's dominions by refugees from Sholapur in British territory and from village to village by human agency, 5425, 5431, 5498.
Hyderabad State: Introduction of plague by a Banniah to Kajurgi, I. 199.
Igatpuri: Plague imported from Bombay by a Muhammadan, who died of plague after arrival, 19,454.
Igatpuri: Plague imported by people who came in with plague either from Poona and Bombay, 16,884.
Ilkal: Plague introduced by Banniah who came in from Poona and died, 19,512.
Infection carried by an inoculated person, who himself remained free, 10,753.
Infection carried by human agency, 24,391–8.
Infection of villages can always be traced to human agency, 14,757.
Instance in which infection conveyed by persons suffering from plague from village to village, 5498–5506.
Instances in which infection was carried through human beings, III. 228.
Kaira district: Plague in the villages of, imported by persons who came from Umreth and other infected places, 14,053–4.
Khandraoni: Plague introduced at Khandroni from Bombay by person who came and sickened, 9636–7.
Malegaon: Infected by refugees from Bombay, 13,774.
Nasik infected by human agency, which also spread the plague in the district, 14,693–4, 16,966.
Palanpur State: Plague introduced from Bombay by a Banniah, who fell ill after his arrival, 6414, 13,054.

SPREAD OF PLAGUE—*cont.*

Palanpur State: Villages infected from persons who came from the town and developed the disease, 13,110.
Panjab: Introduction of plague from Hardwar to Khatkar Kalan by a man who sickened after returning from Hardwar, 9919.
Panjab: Policeman and hospital assistants often contract plague, 9968.
Panjab: Source of infection in 67 cases traced to human agency, 10,079.
Poona: Plague imported by a Mali from, to, 24,133.
Porbandar: Plague spread from the Kharwas' quarter to that of the Bhois and Borahs, 13,680.
Porbandar: Plague spread from the Kharwas to the Muhammadans, the Turias, the Julalas, the Sepoys and Memons, 13,705.
Satara district: Traced to human agency in seven villages; conveyance generally by human agency, 22,678, 22,690.
Sholapur: Conveyance by people, 24,016.
Sirohi: Disease introduced by a Banniah from Poona, who sickened after his arrival, 9702.
Surat: Carried by human agency, 2039.
Surat: Infection brought by people who came back infected from Bombay, 24,409.
Surat: Golas spread the infection to the other quarters, 16,064.
Trading classes having permission to travel principally the means of spreading the epidemic, 23,607.
Undiscovered cases most dangerous source of, 10,994.

See Banniahs and Traders.
,, Rats.
,, Clothes.
,, Merchandise.

Instances and Opinions that Human Agency not the Means by which the Plague spread:

Bulsar: Difference of caste makes it improbable that the plague could have spread from the Dhebras to the Tais by human agency, 16,179.
Surat: Theory that plague not imported by people who came from Bombay and sickened in Surat, 16,137.
The danger from infected persons of the poorer classes in India has been much overestimated, 987.
The disease not generally spread by human agency, 1165.

Railways, spread along:

Baroda: Plague imported by railway passengers from Bombay, 15,194.
Case of conveyance of plague along the railway by sick persons, 20,086.
Carried chiefly by the railway, 5508.
Carried chiefly by railway passengers, 1307.
Carried by railway from district to district, 1644.
Jeypur: Case of plague at Jeypur in December 1896 in a man who came by rail from Bombay and then sickened, 6406–10.
Poona: First cases imported by railway passengers from Bombay, 12,857.

See Bangalore.
,, Calcutta.
,, Hubli.
,, Railway measures.
,, Importation of cases.

Sea, spread over:

Daman: Infected in 1897 by a coasting vessel from Karachi, 16,348, 16,386.
Daman: Infected by sailors from Karachi, 15,959.
Risk of passengers bringing plague by sea much less than by rail, 12,199.
Tamatave not infected by ships going direct from Bombay, 25,494, App. LXXVI., Vol. IV.

See Bombay.
,, Karachi.
,, Ships.

SPREAD OF PLAGUE—*cont.*

Spread of Plague slow:

Slow spread in first epidemic, Karachi, 11,105,
Slow spread in Hubli, 1645.
Spread slow and infection localised both in towns and over the country, 26,537.

Theories and Observations regarding the Spread of Plague by agencies other than men and rats:

Hubli: Plague spread by continuing to appear just outside the limits of an evacuated area, 1645, 1710.
Karachi: Plague spread to the houses next evacuated blocks, 11,315.
Plague spread by clothes, rats, and some undetermined factor in the grain shops, 11,278, 11,430.
Porbandar: Disease spreading from a centre gradually outwards, 13,696.
Proceeds along the ground, 2252.
Suggestion that plague may spread from a centre by growing outwards along the ground, 1707.
Theory that plague cases spread at Jawalapur in concentric rings round about the contaminated focus, 9276-8 (9480, 9579).

See Inoculation with Haffkine's plague prophylactic.
,, Wind.

SPUTUM:

Clinical Features of Plague:

Description of sputum in pneumonic plague, 7192.
Diplo-cocci common in the sputum of plague patients in the first stage of the disease, 25,339.
Early stage at which the sputum becomes fœtid one of the characteristics of pneumonic plague, 7465.
In cases of hypostatic congestion little sputum, 20,822.
Only two cases of pneumonic plague in which the sputum was copious, 9551.
Pneumo cocci found as frequently in the ordinary normal sputum as in plague cases when the lungs and bronchi are affected, 26,301.
Sputum in pneumonic plague offensive, 7464.
Sputum in pneumonic plague very profuse and mixed with much blood, 1514.
Sputum resembles sometimes that of ordinary pneumonia, in others is thin and watery, 7193.

Discovery of Bacillus in Bubonic Plague:

Bubonic patients, not found in sputum of, 10,443, 17,265.
Bubonic patients, no cultures from sputum, though baccilli microscopically like plague present in many cases, 26,257.

Discovery of Bacillus in Pneumonic Plague:

Bacillus found in sputum several days before death, 17,196.
Bacillus recoverable from sputum during life, 1436, 1789, 7196.
Found in pure cultures in the sputum of pneumonic plague, 20,406.
Found in the sputum of patients with pneumonic plague, 10,437, 17,258, 17,268, 25,305.
In one case plague bacilli found in the sputum of pneumonic plague patients 28 days after lung symptoms had developed, and 3 days after the temperature had become normal, 25,342-6.
Isolated from floor scrapings contaminated with sputum, 4547.
Results of experiments to determine period of survival of bacillus in grain mixed with sputum, II. 18.

Spread of Infection by:

Danger of infection from expectoration of patients, 26,720.
Floor, clothes, and pneumonic sputa the only factors which have proved to be infective, 21,717.

SPUTUM—*cont.*

Infection of bubonic plague through sputum and saliva, 17,985.
Infection carried through the air by dry sputum, 20,626.
Pneumonic plague, infection communicated by breath and sputum, 504.
Sputum of plague patients most important means of infection, 22,371.

See Habits of people affecting liability to plague.
,, Pneumonic Plague, *Infectiousness of.*

SQUIRRELS:

Affected in Kaira district, 14,076.
Affected at Banga, 10,136.
Affected at Bangalore, 2600, 2654.
Artificially inoculated die of plague, 11,523.
Died during plague epidemic in Poona cantonment, 21,295.
Died of plague at Ankleshwar, 14,243, 14,492.
Died of plague in Baroda, 14,641-94.
Died of plague at Bhiwandi, 14,493
Died at Hubli: On microscopical examination one found to have bacilli like plague, 3116, 3119.
May have some influence in spreading plague, 22,064-9.
Seen dropping dead from houses, 3597.
Seem to die off more quickly than rats during the epidemic, 3120.

STAFF, PLAGUE:

Details of:

Anand: Detention camp, details of staff, 14,152-7.
Banga: List of staff employed in the operations against plague, 10,272.
Bombay: List of staff employed in the Health Department up to the end of September 1896, and that to the end of February 1899, III. 313.
Bombay: Population of "C" ward 140,000; only 150 men to work it with, 10,950.
Broach: Abkari inspection, village watchmen employed at Broach on plague measures, 15,483.
Dharwar district: Staff on plague duty in, 2164, 23,163.
Hardwar: Statement of number and pay of persons employed in the special medical establishment at, during the two epidemics, II. 51.
Hardwar Union: List of officials employed in, between June 1st, 1897, and April 1st, 1898, II. 51.
Health Inspectors on their rounds obtain information of cases from residents or sweepers, 14,435.
Panjab: Establishment employed in, 10,272.
Poona: Enormous staff of soldiers and civilians, European and Native, 21,269.

Efficiency of:

Bangalore: Breakdown of Health Department employés' strike in Bangalore, 2556.
Continual change of plague officers in the wards is prejudicial to the success of the measures, 17,961.
Insufficient staff the principal cause of the failure of plague measures, 22,084.
Most men now engaged in plague work are absolutely incapable of diagnosing case of septicæmic plague, 20,135.
Strike of conservancy establishment in Calcutta, I. 471.

Employment of Soldiers and Police on:

Ahmedabad: People prevented from leaving detention camps at, by police supervision, 13,898.
Bangalore: Police and soldiers necessary to accompany the medical officer on plague duty, 2573.
Bangalore: No complaints against the soldiers, 2633.
Calcutta: Police activity in discovering cases objected to, I. 469.
Cases among police and Hospital Assistants on plague duty frequent in the Panjab, 9,968.

STAFF, PLAGUE—*cont.*

Cases among police on plague duty, 7220.
Hyderabad State: Soldiers posted in every infected village to control movements of the people, 5465.
Hyderabad State: Staff employed in looking after people taken out of their houses usually four soldiers; sometimes eight employed, 5858.
Khandraoni: Four hundred and fifty-six soldiers employed on the plague measures, 9694.
Kotri: Willingness to co-operate with the Government from dread of the military, 12,677.
Malegaon: Soldiers employed as patrols, 13,803.
Malir camp surrounded by thorn fence and guarded by police and Sepoys, 12,441–5.
Natives have greater fear of the soldiers than of the police, 13,804.
People more afraid of plague officers than of plague, 15,130.
Poona: Disinfection done under supervision of British soldiers, 21,289.
Poona: Soldiers employed on the plague staff, 21,494, 21,766.
Rohri: Soldiers employed, 12,607.

European Supervision, Necessity for:

Measures cannot properly be carried out without European agency, 23,660.
Number of European staff insufficient everywhere, 24,030.
Special European health officers employed on plague duty, 1621.
Supervision should be carried out strictly by Europeans who understand the natives and respect their prejudices, 18,487.

Native Agency:

Native agency not reliable without European supervision, 8068–9, 22,915.
Native officers indispensable in dealing with the prejudices of the people, 8821.
Native subordinates apt to levy blackmail if left alone, 8271.
No complaints against native officials, 3956.
Reliance on native agency only admitted to a certain extent, 23,269.

Supervision of Medical Men:

Duties of Civil Surgeon leave him no time to look after plague, for which measures must be supervised by civil officers, 7913–4.
Medical Officer alone should be the organiser and director of plague measures, 20,089.
Non-medical men as inspectors a great drawback for the right diagnosis of cases, 9963.
Plague Commissioners sometimes laymen through lack of medical men, 7969.

See Flying columns.
,, Disinfectors.
,, Volunteer agency.
,, Ward system.

STAINING CHARACTERISTICS OF BACILLUS OF PLAGUE:

Bi-polar:

Bi-polar staining not alone sufficient as a differential diagnostic of the plague bacillus, 8658, 27,333.
Bi-polar staining a very characteristic feature, 5720, 27,331.
Bi-polar staining very much less marked in the microbe of culture than in that obtained from blood of plague patients, 26,125.

Gaffky's Method:

Gaffky's method the best for polar staining, 8660.

Thionine blue:

Bacillus of plague stains readily, I. 441.

STALACTITE FORMATION OF BACILLUS OF PLAGUE:

Characteristic stalactite formation, 27.
Disputed plague cases, stalactite formation obtained from cultures in, 8424, 8426, 8428.

STALACTITE FORMATION OF BACILLUS OF PLAGUE—*cont.*

Haffkine's test most reliable for differentiating the stalactites of plague bacillus from those of other microbes, 8663.
In Jawalapur, bacilli at beginning of outbreak formed typical stalactites, but did not do so at end of the outbreak, 8662.
Stalactites not distinguishable by mere inspection from plague stalactites formed by other microbes, 8663.

STANDARDISATION OF HAFFKINE'S FLUID:

See Inoculation with Haffkine's plague prophylactic.

STEAM.

Clothes, personal effects, or leather goods not spoiled by steam disinfection, 12,189.
Clothes disinfected under steam pressure for 30 minutes on railway, 14,513.
Clothes disinfected by steam at Karachi since the beginning of 1898, 12,154.
Clothes disinfected by steam at temperature of 225° on railways, 1315, 1318.
Clothes disinfected at railway station by steam at a pressure of 15 lbs. to the square inch for least a quarter of an hour, 25,397.
Clothes of railway passengers at Poona disinfected by steam, 4027.
Clothing disinfected in Anand Hospital by steam, 14,127.
Clothing imported from infected places sent to Kiamari camp for disinfection by steam, 12,017.
Disinfection by steam recommended, as personal effects are not spoiled by it, 12,159.
Gunny bags imported from infected places sent to Kiamari camp for disinfection by steam, 12,017.
Method of disinfection by steam on railway at Tungabhadra, 4528–40.
Steam treatment for plague, Vol. II., App. A.

STERILITY OF HAFFKINE'S PLAGUE PROPHYLACTIC.

See Haffkine's plague prophylactic.

STOMACH:

Post-mortem Appearance:

Abdomen in septicæmic cases, I. 439.
Digestive system in, septicæmic case, I. 440.
Petechiæ of the stomach a noticeable feature in post-mortems after bubonic plague, 10,419.
Post-mortem appearances of intestines, 1420.
Post-mortem examination of stomach, 1420, I. 367.

Possibility of Infection by Stomach:

No post-mortem evidence that bacillus had had entered by the stomach, I. 375.
No post-mortem evidence to show that food brought infection, I. 368.

STRENGTH OF HAFFKINE'S FLUID:

See Inoculation with Haffkine's prophylactic.

SUBSOIL WATER:

Backergunge:

The water-logged condition of, accounts for the purely pneumonic type of outbreak, I. 262.

Bombay:

Connexion between the epidemic and high sub-soil water, 26,108, 26,111.
Damp soil makes it unhealthy in Bombay, 15,972.
Excess of sub-soil moisture, &c., the predisposing conditions to plague, 17,354.
Plague cases mostly abound where the soil is water-logged, 18,340.
Plague in Bombay followed in the course of the sub-soil water, 17,956.
Rise of sub-soil water one of the conditions preceding outbreak of plague in Bombay, 25,268.

SUBSOIL WATER—*cont.*

Water-logged condition of the soil in Bombay accounts for the outbreak, 19,195.

Effect on Plague:

Places with good and bad drainage compared, 23,363.

SULPHUR:

Daman: Quicklime and sulphur used, and considered quite as effective as expensive disinfectants, 13,458, 25,448.
Experiments show that sulphur fumigation is useless, II. 12.
Tried in Rohri at commencement of epidemic, but abandoned as useless, 12,029.
Used in Baroda: comparative statistics of efficiency, II. 258.

SULPHURIC ACID:

Madras: Used for disinfecting slimy mud of court yards, 3927.
Malegaon: Used as disinfectant; to re-appearance of plague, 18,180.
Result of tests for disinfecting with, II. 8.
Surface drains, sulphuric acid dilute most suitable for, II. 13.

SUN:

Action of Sunlight on Plague Bacillus:

Growth could not be recovered in any instance from cultures exposed to sunlight for four hours, 26,342.
Heat of the sun sufficient to destroy plague microbes, 814.
Plague infected calico rendered sterile by exposure to sunlight, 26,342.
Three hours' exposure to strong sunlight of infected flannel, cotton wool, and cloth greatly retards the development of the bacilli, 26,342.
Vitality of the bacillus of plague diminished by the sun, 17,031.

Clothes, disinfected by Sunlight:

Clothing dipped in phenyle and spread out in the sun used as disinfecting method, 10,048.
Cotton or clothes exposed to the sun for six hours, 10,317, 10,935
Disinfection of crews kit and clothes by exposure to sun and air, 738, 814.
Nassarpuri camp: Exposure to sun the only method of disinfection used, 11,490.
Silks, &c. exposed to sun and air for disinfection in Karachi, 11,650.
Sun and air sufficient for disinfecting cotton goods, 11,484.
Sunning and washing clothes sufficient for disinfection, 24,037.

Grain disinfected by Sunlight:

Grain exposed to the sun for six hours, 10,317, 10,935.
Grain sun-dried at Hinganghat to disinfect it, 6066.
Grain infected by the excreta of rats disinfected by exposing it to sunlight, 9459.

Efficacy of Disinfection by Sunlight:

Benefits of disinfection by exposure to sun and air shown in Salaya, 13,474.
Exposure of infected area to sun and air the most beneficial measure of disinfection, 13,643, 17,646.
No plague after exposure of dug-up floors to sun, 23,778.
Sun does the work much better than chemicals 24,342.

See Unroofing.
,, Untiling.

SUPERNATANT FLUID IN HAFFKINE'S PLAGUE PROPHYLACTIC.

See Haffkine's plague prophylactic, *constituents of.*

SURVEILLANCE:

Ahmedabad: Municipal inspectors to keep arrivals under observation are laymen, 13,871.
Bombay: System applied to persons landing from infected ports or ships, 772.
Broach: Guards at railway stations kept out people from infected areas; people coming in were kept under surveillance, 15,483.
Hardwar Union: Large area placed under an organised system of observation, 8869–70.
Nasik: Notification of arrivals from infected places within six hours, and inspection works well, 24,515.
Poona: System adopted at, 21,528, 21,769–71.
Surat: Passenger kept under surveillance, 2062.
See Observation Circles.

SURVIVAL OF BACILLUS OF PLAGUE.

See Period for which plague bacillus can survive.

SYPHILIS:

Belief that syphilis protects against plague, 8694.
General belief that prostitutes under syphilis are immune, 8693, III. 43.
People who have had syphilis survive a much more severe type of plague than a person who has not, 22,487.

TEMPERATURE:

See Cold weather.
,, Cultures.
,, Hot weather.

TEMPERATURE IN PLAGUE CASES:

In one case, 106, 1861.
Mild case, 99·4–101, 4550.
Pyrexia of plague remittent; of glandular fever intermittent, 6982.
Regular course much affected by complications. I. 379.
Remittent; difference of 1 or 1½ degree between morning and evening, 20,694.
Rises more quickly and is greater in children than in adults, 20,689.
Rises sometimes to 107 or more before death, I. 380.
Severe symptoms not always corresponding with a rise in temperature, 11,574.
Sudden fall generally associated with collapse and death, 20,699.
Temperature no criterion in plague cases, 18,312.
Temperature variable; no criterion of gravity of cases, 20,686–94.
Virulent cases 107 or 108, 20,686.
See Haffkine's curative serum.
,, Inoculation with Haffkine's plague prophylactic.
,, Lustig's curative serum.
,, Maps and charts.
,, Medical treatment, European.
,, Yersin's curative serum.

TEMPERATURE AFTER INOCULATION WITH HAFFKINE'S PLAGUE PROPHYLACTIC.

See Inoculation with Haffkine's Plague Prophylactic.

TONGUE:

Clinical Features of Plague:

Appearance of tongue varies with the character of disease, 20,831.
Appearance of tongue the only difference between the disputed cases at Bombay and Calcutta, 8214–5.
Condition of tongue most important, 8215.
Furred and patchy, 8222, 12,398, 12,937, 15,294.
Glossitis, 20,835.
No raw tongue seen at Bombay, 8224.
Paralysis of the tongue, 16,537.

Discovery of Plague Bacillus:

Found twice in the fur at the back of the tongue out of 20 cases, 27,055.

TRADERS.

See Banniahs and Traders.

TREATMENT OF THE SICK IN THEIR OWN HOUSES:

Ahmedabad: Isolated in the houses of the patients, first cases at, 13,866.
Bangalore: Measures at, relaxed to allow of home segregation, 3293.
Belgaum: Sick treated in their houses; epidemic increased, 23,815, 22,821–3.
Belgaum: In second epidemic patients allowed to remain in their own homes, with good results on reporting of cases and prevention of scattering of people, 23,138.
Bhiwandi: 1,625 sick treated in their own houses, and only 153 in hospital; results not good, 22,116–9, 23,359.
Bombay: Good results of isolating the sick in their own homes, 17,870.
Bombay: Isolation of plague patients in their own houses impossible in the chawls, 25,564.
Bombay: Under the present system of not removing patient to hospital, except by the desire of his friends, concealment of cases is the exception, 25,815.
Bulsar: Concessions, namely, treatment of sick in their own houses, given to inoculated, prevented the concealing of cases, 16,291.
Calcutta: Airy houses in Calcutta licensed as family hospitals with good results, 6588–9.
Calcutta: Second epidemic; policy of treating sick in their own houses adopted, II. 532.
Constant intercourse between the sick and healthy outside, the evil of home treatment, 12,178.
Home treatment does not tend to spread plague, and renders carrying out of disinfection easier, II. 537.
Home treatment of people sick with plague a very bad measure with regard to the spread of the epidemic, 12,332–6.
Home treatment ought not to be allowed in houses of a long row, 25,831.
Isolations in people's own houses under favourable conditions and proper precautions not dangerous, 22,510.
Permission to some people to treat their sick in their houses makes it more difficult to enforce isolation of others, 19,665.
Poona: Home treatment allowed with antiseptic precautions, 21,940.
Poona: In two cases where patients were allowed to be treated in their own houses, the results were so disastrous that the trial had to be given up, 25,828–9.
Poona: Parsees in Poona treated at home successfully, as they adopt hygienic measures while treating the sick at home, 12,879.
Treating patients in their houses a very bad measure, 22,118.
Treatment of sick in their houses at Mysore successful, as people reported cases, and were not impelled by fear to scatter and spread the plague, 24,960.
Unless a private house can be placed under the conditions of a hospital, home treatment of patients should not be attempted, 25,827.

TYPES OF PLAGUE:

See Atypical forms of plague.
,, Bubonic plague.
,, Bullæ.
,, Clinical features of plague.
,, Pestis minor.
,, Pneumonic plague.
,, Post-mortem appearances in plague.
,, Septicæmic plague.

TYPES OF PLAGUE IN PARTICULAR EPIDEMICS:

Anantapur district: Pneumonic cases not more than 4 or 5 per cent., 4462.
Ankleshwar: Very few pneumonic cases, 14,268.
Backergunge district: Course of pneumonic epidemic, I. 262–6.
Bombay: First epidemic bubonic, 19,067.
Bombay: In first epidemic cases easily distinguishable, 19,471.
Bombay: Second epidemic bubonic, and pneumonic from middle of epidemic in February and March, 1898, 19,067–70.
Bombay: In second epidemic no buboes or swellings, and cases hard to diagnose, 19,471.

TYPES OF PLAGUE IN PARTICULAR EPIDEMICS—*cont.*

Bombay: Third epidemic virulent, with much pneumonia 17,888.
Bombay: Third epidemic almost pneumonic in character, but with enlarged glands; in February 1899 mainly bubonic, very fatal, 19,071–5, 19,077.
Bombay: Epidemic 1898–9, at first primary pneumonia very frequent, at end of February very few cases, 21,043.
Bulsar: Non-bubonic plague appeared first in 1897, 16,314.
Chipagiri: Little pneumonic plague, 4461–2.
Cutch: At first of a virulent type, then chiefly pneumonic, then chiefly bubonic; in second epidemic more bubonic and less virulent, 13,488–93.
Cutch: In Salaya chiefly pneumonic and septicæmic, 13,490.
Cutch: In the epidemic at Sarli no pneumonic cases 13,619.
Daman: Epidemic of 1898; a form of plague noticed, accompanied by bullous inflammations, 16,794.
Daman: Pneumonic plague with other types of plague found, 18,794, 18,842.
Gharibabad: Was infected with pneumonic plague, 11,163.
Hardwar: Majority of cases bubonic, pneumonic cases noted after January 1898, 9170–1.
Hyderabad (Sind): In 1897 epidemic bubonic, with few pneumonic cases, 18,093–4, 18,151–3.
Hyderabad (Sind): A fairly large number of pneumonic cases, 18,439.
Kotri: Cases mostly bubonic, 12,700.
Nasik: Only 5 pneumonic cases which did not occur in the same house, 14,705–11.
Poona: Virulence of type of imported cases since February 1899, shown by the proportion of deaths, 25,827.
Porbandar: Only 6 pneumonic cases treated in hospital, 13,724–7.
Satara: Pneumonic plague cases not numerous, 22,153.
Sukkur: Pneumonic plague fairly common, 18,439.

Pneumonic Plague: Prevalence of Pneumonic Cases in Particular Epidemics:

Cases with lung symptoms vary in frequency at different periods of an epidemic, 21,042.
Cutch: Pneumonic cases most prevalent in, at height of epidemic 18,202–4, I. 352.
Palanpur: Pneumonic cases observed in, chiefly in the height of epidemic 13,104–5.
Poona: Pneumonic cases more frequent in, when the epidemic most severe, 12,915.

See Pestis minor.
,, Virulence of plague in different phases of an epidemic.

UMARKHADI COMMON JAIL, BOMBAY, PLAGUE IN, AND INOCULATION WITH MR. HAFFKINE'S PROPHYLACTIC IN.

A number of cases took place in one particular spot in spite of its disinfection with quick lime, 20,332–46.
Clinical records of two persons inoculated in the Jail and subsequently attacked by plague, one case resembling mumps, 69, 7236, I. and II.
Correspondence with Mr. Haffkine regarding the correctness of the inoculation returns relating to the Umarkhadi Jail, III. 658–61.
Inoculations performed in the Umarkhadi Jail, 69.
No selection of cases for inoculation in the Umarkhadi Jail, 20,115–31, 26,500.
Particulars of the inoculations in the Umarkhadi Jail in January 1898, 17,099–112.
Prisoners not selected for inoculation, 20,311–6.
Re-inoculations in the Umarkhadi Jail, 11,714–27.
Report by Lieut.-Colonel Waters, I.M.S., on the inoculations in the Umarkhadi Jail, 113, 117.
Results of inoculation, 20,317–31.
Statement of particulars regarding inoculation and plague in the Umarkhadi Jail, Bombay, III. 441–4.
Umarkhadi Jail much overcrowded during the epidemic of plague, 20,341.

UNDHERA, PLAGUE IN, AND INOCULATION WITH MR. HAFFKINE'S PROPHYLACTIC IN:

Ages of the inoculated, 14,910, II. 510.
Census made of Undhera, and mortality figures prepared by a subordinate Medical Officer on the spot, carefully checked house by house, statistics for inoculated and uninoculated, 4,035–61.
Census taken at the beginning of the epidemic, 14,892–900, II. 504.
Deaths among uninoculated most numerous directly after the inoculations were performed, 18,708–13.
Gross mortality for three months before the outbreak of plague, 14,882.
Gross mortality from plague and other causes after the introduction of inoculation, 14,912–5.
Gross mortality from plague and other causes and plague attacks, 14,908–9, II. 510.
Inoculations performed at Undhera, 69.
No selection of cases for inoculation in Undhera, 26,500.
Report by Mr. Haffkine on inoculations in Undhera, I. 331–6.
Statement of weekly gross mortality for three months before December 22nd, 1897, II. 266.
Statistics of plague and inoculations in Undhera, 26,535.
System of selection for inoculation, 14,902–7, 14,918–9.
Table of gross mortality before the first case of plague, 14,882.
Total number of uninoculated persons, 14,885–92.
Undhera figures carefully checked, results accurate, 7872–8.
Undhera, statistics checked and investigation sheets prepared, 161–3.

UNROOFING:

Bangalore: People object to removal of roofs, 3419.
Better class houses disinfected with chemicals, poorer houses unroofed, 23,924.
Bombay Presidency: Houses unroofed, 8.
Dharwar: Houses unroofed, 23,163, 23,748, 23,773.
Dharwar: In the villages chief reliance on unroofing, 1680–2.
Entire unroofing of infected houses the most effective measure of disinfection, 22,667.
Kalindri: Resorted to as disinfecting method, 9894.
Karad: Roofs taken off and opened up, 21,078.
Panjab: Entire roof removed and ventilation holes made, 10,027.
Poona: Houses unroofed or partially unroofed, 10,933, 21,289.
Satara: Sadar Bazar in first epidemic unroofed as a precaution, and escaped; in second epidemic not unroofed, and suffered, 22,273–4.
Satara: Strips of the roof, three feet broad, taken off, 22,157.
Sholapur: Poorer houses unroofed, 23,924.
Unroofing recommended for villages as the application of the measure can be easily checked, 21,156.
Unroofing the great thing as disinfecting method, 1681.

See Houses, disinfection of.
,, Ventilation.

UNTILING:

All small houses in Bombay untiled, 1240.
Calcutta: Untiling resorted to, 6532.
Cutch Mandvi: Tiles removed about a yard in width, 13,474.
Dharwar: Houses untiled, 23,434.
Disinfection by untiling roofs at Sholapur, 8.
Guntakal: Openings made in roofs, 5099.
Hubli: Houses untiled, 2404.
Palanpur: Untiling resorted to as method of disinfection, 13,091–4
Removal of tiles must be on generous scale, 6616.
Sirohi: Roofs untiled, 9911.
The removing of the tiles from the roofs only good in the case of basement houses, 13,474.
Untiling adopted in Bangalore and Mysore, 25,003.

UNTILING—*cont.*

Untiling useful both in admitting light and air, and also in driving rats out of roofs, 1220.

See Houses, disinfection of.
,, Ventilation.

URINE:

Clinical Features of Plague:

Urine diminished in quantity, of high specific gravity, and intensely acid, I. 380.

Discovery of Bacillus in:

Bacillus found in, before death, 3556–63, 3647–9.
Bacillus found in, in 2 cases before death, 7200–3, 7270.
Bacillus cultivated after death, 1436.
Bacillus of plague will only be found in urine when it contains blood, 22,367.
Bubonic plague found in the urine of patients dead of, 17,261.
Can be cultivated from urine after death, 14,367.
Found in urine during life, 3556, 3564, 7189.
Found in urine when it contains blood, 22,367.
Not found in urine in about 15 examinations, 25,358–62.
Not found in a number of cases examined, except once, when bacillus recovered from organs of animal inoculated with the urine, 26,268, 26,336.
Only twice found in urine in 20 or 30 cases, 7206–7.
Only twice isolated from the urine in 50 plague cases, 26,389.
Results of 50 analyses at Bombay Hospital, I. 396–7.
Results of 50 examinations of urine at Bombay Hospital, I. 396–7.

Life of Bacillus in:

Bacillus of plague grows more slowly when obtained from the urine than from the blood, 26,337.
Lives 24 hours in urine at least, 3611.

Prognosis:

Free excretion of urea and uric acid good prognosis, 20,860.

See Rats.

URINARY SYSTEM:

Discovery of Bacillus in:

Recovery from the urethra of a patient dead of bubonic plague, 17,258.

Post-mortem Appearances:

Of urinary system, I. 367.
Of urinary system in septicæmic case, I. 440.

VACCINATION DEPARTMENT:

Advantages of classifying native vaccinators, and promoting by merit, 7769.
Great advantages to have Hospital Assistants among vaccinators, 7770.
Organisation for vaccination, 7751.
Qualified Assistant Surgeons in Vaccination Department would be of material help in detecting cases of plague, 8884.
Scheme by which Assistant Superintendents of Vaccination would be Assistant Surgeons with a knowledge of sanitation, 8881.

VENTILATION:

Attitude of the People towards:

Ahmednagar: People close up windows and ventilation holes made, and enforced opening of windows necessary every morning, but people may in time come to appreciate ventilation openings, 24,203–9, 24,361–2.
Bangalore: People now ask for their houses to be ventilated, 3269.
Bangalore: People object to openings in their houses, 3419.
Baroda: The people, except the Machis, seem to approve of improvements in ventilation, 19,159–65.
Desire to secure privacy excludes ventilation, 867.

VENTILATION—*cont.*

Native servants close up all ventilation openings in their quarters, 20,539.
Panjab : People close up ventilation holes as soon as possible, 10,271.
People apt to close up the openings made in their houses when allowed to return, 12,077.
People close up ventilation openings at night, 19,515.
People plaster up holes made for ventilation, 23,404.
Satara : People more inclined to ventilation, 22,432-4.

Disinfection by :

Ahmedabad : Ventilation resorted to as disinfecting method, 13,923.
Ahmednagar : Openings made in houses to admit the sun, 24,274.
Baroda : Uninfected houses cleansed, white-washed, and ventilated as disinfecting precaution, 14,631.
Panjab : Ventilation holes made in roofs and side walls to disinfect, 10,481.
Surat : Houses opened up, and then swept out and doused with perchloride solution, 24,434.

Effect on Plague :

Bad ventilation the causes of the disease 14,716.
Bad ventilation one of the principal factors in the propagation of the disease, 14,388.
Cases less frequent among those who sleep in the open air, 7517.
Connexion between ventilation and the disease, 916.
Contagion lessened by ventilation, 12,881, 18,569.
Great difference in the intensity of plague in ill-ventilated and well-ventilated houses, 14,390–1.
Infective material retains its vitality for a long time in badly-ventilated houses, 9725.
No plague after ventilation of dug-up floors in Kalgeri, Dharwar, 23,778.
Over-crowding and bad ventilation the causes of the disease, 14,716.
Plague at Kiamari principally in badly-ventilated houses, 11,971.
Remarks on conclusions derived from experiments as to the efficacy of ventilation, II 13.
Satara Jail : Infection did not spread on account of good ventilation, 22,330.
Statistics of effect of ventilation on disease, 916.

In various Places :

Ahmednagar : Ventilation arrangements in houses bad, 24,275, 24,347.
Bangalore : Ventilation in houses bad, 3254,
Bombay : Houses badly ventilated, 26,645–8.
Bombay : Houses inefficiently ventilated from narrow galis, 835.
Bombay : No ventilation at night in bad houses, 847.
Bombay, Kamatipura : Houses low and badly ventilated as well as over-crowded, 17,834.
Cutch Mandvi : No ventilation in houses, except by the door, 13,355.
Dharwar : Ventilation bad, 1711, 23,185, 23,518.
Hubli : Houses remarkable for their bad ventilation, 20,144, 20,207.
Karachi : No free passage for air in houses at Kiamari, 11,971.
Karachi : Ventilation much improved since epidemic, 22,664.
Nasik : No ventilation except by the door, 13,786–7, 16,983.
Satara district : Many houses in the Taluka have not been ventilated for years, 22,734.
Surat : Most localities absolutely without ventilation, 15,937, 16,107–8.
Surat : Only ventilation often through door, 15,937.
Thana district : Houses poor, with no outside opening but door, 19,690–3.

Opinions regarding Ventilation as a Plague Measure :

Chemical disinfection unnecessary if vacated for three months and ventilated, 24,040.
Disinfection by ventilation, II. 13.

VENTILATION—*cont.*

Houses should be permanently improved by ventilators and windows, 22,667.
Ventilation as effective as disinfection by chemicals only slower, 23,259.
Ventilation best method of disinfecting, 23.662.
Ventilation holes in roofs very useful way of disinfection, 10,026.
Ventilation the most important sanitary measure to be enforced, 19,515.

See Air and Light.
,, Desiccation.
,, Sanitary Conditions.
,, Unroofing.
,, Untiling.

VIRULENCE OF BACILLUS OF PLAGUE :

Attenuated through the effects of involution, 8520.
Attenuated by being passed through rats, 8675, 26,311–4.
Change in the bacillus of plague after it has left the human body suggested to account for infection not spreading in camps, 10,488.
Increased by a series of intra-peritoneal passages through guinea-pigs, 26,434c.
Increased by filth, 18,635.
Increased by filth : Weak or attenuated germs require environment of filth to cause development of plague, 18,633.
Increased by passing through animals, 18,641.
Increased by passage through monkeys, 26,547-8
Increased by passage through rats, 17,423.
Increased by passing through mice, 8677.
Maintained by passages through rats, 26,464.
Plague germs become virulent after the rains, 22,356.
Plague germs may be of a non-pathogenic nature, and of different degrees of pathogenic viralence, 18,630.
Test of virulence by inoculation into the peritoneum surer than by subcutaneous injection, 17,413.

VIRULENCE OF PLAGUE IN DIFFERENT PHASES OF AN EPIDEMIC :

Lessened towards Decline of Epidemic :

Cases live longer towards the end of an epidemic, 17,714.
Disease becomes milder in form towards the end, 18,102.
Larger percentage of patients recover at the end of an epidemic, 21,047.
Most marked decrease in virulence at the end of the epidemic in Savali, 14,667.
Virulence abates towards end of epidemic, 15,907.
Virulence in Baroda lessened at close of epidemic, 14,242, 14,634.
Virulence of epidemic always subsides towards the end, 15,112.
Virus becomes weaker towards the end of the epidemic, 13,741.

Not Lessened towards Decline of Epidemic :

Cases as virulent during the subsidence as at the beginning, 12,512.
Does not decrease towards close of epidemic, as in cholera, 6938.

Statistics bearing on :

Ankleshwar, 14,404.
Igatpuri, 19,493.
Ilkal, 19,493.
Porbandar, II 484.

See Types of plague in particular epidemics.

VITALITY OF BACILLUS OF PLAGUE.

See Period for which plague bacillus can survive.

VOLUNTARY EVACUATION :

Advantages of :

Although evacuation is only partial in voluntary camps, it decidedly reduces the number and virulence of the attacks, 11,901.
Intelligent voluntary action of the people will soon reduce the expenditure involved in, 26,543.

VOLUNTARY EVACUATION—*cont.*

Securing of all contacts one of the advantages of voluntary camps, 11,821.
Voluntary camps of great help to the Government officials, no pressure being needed, 11,903.
Voluntary evacuation works much better than coercive measures, 11,265.

Arrangements for:

Baroda City: Forty thousand people in fields round the city, not in Government camps, 14,677.
Baroda: Unauthorised camp at, under no organised control or supervision, 14,627.
Broach: Have their own organisation and administration at, 15,503.
Broach: Camp arrangements at, voluntarily and successfully carried out, 15,484.
Cutch Mandvi: Borahs went into segregation camps in, and suffered little, although under no control, 473, 566.
Cutch Mandvi: People refused to go to Government camps, but 20,000 left the city, and, as they were prevented by guards from scattering, camped in gardens around, 13,378–9.
Karachi: Boundaries of voluntary camps at, 11,869.
Karachi: Conditions under which voluntary evacuation was allowed, 11,868.
Karachi: Largest voluntary camp at, that of the Baluchis, containing 2,851 persons, 11,911.
Karachi: Trans Lyari, good success of people appointing their own plague committee in the voluntary camps of the, 11,258.
Karachi: Thefts being frequent in voluntary camps, the people applied for regular police protection, 11,883.
Karachi: Twenty-five thousand people in voluntary camps, 11,260.
Karachi: In most of the voluntary camps some Banniahs' shops allowed at the extreme limit of camp, 11,882.
Kotri: Health camps started in second epidemic at, by Seth Vishandas and Muhammadans, 12,655.
Mat huts for the sick in voluntary camps, 11,888.
Not a good plan to have one large camp; the more broken up the better, 5459.
Parsees freely resorted to evacuation at Bombay, 8294.
Supervision: Inspection of the voluntary camp at Nagar by the Abkari police, 18,982.

Attitude of the People towards voluntary Evacuation:

Bangalore: Done promptly and voluntarily by villages around, 3303.
Baroda villages: Voluntary evacuation as soon as rats were found dying in the villages, 14,664.
Carried out by villagers of their own accord after some experience, 9.
Cutch Mandvi: 20,000 persons segregated themselves of their own accord in the gardens round, 13,383.
Karachi: Nassarpuris: Voluntary evacuation, 11,113, 11,120.
Karachi: Lyari, voluntary camps across the, popular, 12,525.
N.W. Provinces: Voluntary evacuation following an outbreak of epidemic among rats, 8839.
Palanpur: People of, built themselves huts in the Mango groves outside the town, 13,084.
Surat: People at, refused to go to Government camps, but made camps of their own, 15,914.
Twenty-six thousand at one time in camp at Karachi, 11,631.
Voluntary evacuation of a whole village at the first appearance of plague, 21,642.

Efficacy of:

Baroda: Mortality in the unauthorised camps at, much less than if people had remained in town, 14,680.
Cutch Mandvi: Not a single plague case among 1,000 persons camped for 2½ months along the seashore, 13,389.

VOLUNTARY EVACUATION—*cont.*

Impossible to prevent people in voluntary camps from going backwards and forwards to their houses, 11,679.
Karachi: Death-rate rapidly decreases in voluntary camps in, compared with the total mortality in the town, 11,784.
Karachi: Mortality in voluntary camps in, compare favourably with the mortality in the town, 11,682.
Karachi: The securing of all the contacts one of the principal advantages of voluntary camps in, 11,821.
Karachi: Table of total number of cases in the voluntary camps at, II. 149.
N.W.P.: Jawalapur: Voluntary evacuation not so effective as Government camps, as huts crowded and not ventilated, and property taken out without disinfection, 9179.
Rohri: The unsanitary condition of the ground in the date plantations the cause of the persistence of the plague in the camp, 12,120.
Surat: In the unauthorised camps at, huts crowded and plague as rife as in the town, 16,016.
Surat: Voluntary camps closed at, as supposed to spread infection, 24,419.
Surat: Plague at once ceased in the voluntary camps at, as soon as they were placed under the control of the ward system, 16,018.

See Camps: *Provision of Accommodation, Food, &c. by the People.*

VOLUNTEER AGENCY:

Bangalore: Volunteer agents failed altogether at, 2553, 3273–6.
Bombay: Native gentlemen serve on plague committees, 5, 1344.
Bombay: Nagpada, one of the best native committees, 1345.
Bombay: Plague committees organised by natives far from efficient in some districts, 1347.
Bombay: Reports from volunteers at present principal source of notification, 25,556.
Bombay: 300 Native assistants do valuable work; description of services, 1345.
Bombay: Voluntary system of reporting plague cases very imperfect, 25,553.
Calcutta: Formation of Vigilance Committee, I. 467.
Calcutta: Vigilance Committee fails to remove contacts, 7610.
Evidence of the relative merits of carrying out plague measures forcibly, and of leaving them to be carried out by the people under a voluntary system is unmistakably in favour of the latter, 24,980.
